The Arris and Gale Lectures

ON

MORPHOLOGY OF THE EXTERNAL GENITALIA OF THE MAMMALS

vered at the Royal College of Surgeons of England on March 4th and 6th, 1914,

FREDERIC WOOD JONES, D.Sc. LOND.,
CTURER TO AND HEAD OF ANATOMICAL DEPARTMENT AT THE LONDON SCHOOL OF MEDICINE FOR WOMEN

264

LECTURE I

Delivered on March 4th

R. PRESIDENT, LADIES, AND GENTLEMEN,—One of atural outcomes of the efforts of naturalists anise the study of the lower forms of life has the desire, manifested in many different ways, sify and arrange the vast wealth of material is available for study. The orderly arrange t of the living world into properly labelled has been the aim of a very long line of nts of nature. There is an attraction about marshalling into ordered array which has ged the attention of even the greatest of alists, has limited the activities of lesser; and has cramped, confined, and stultified whole life work of some of the least among

stems have come and gone, first one set of butes and then another has been claimed as shing the true guide to the position of a living in the vast assemblage of the forms of life. It t proposed to follow the rise and fall of the methods of classification, for it is only with omparatively modern that the present investi- n has any concern. It is assumed that the m of classification into the fabric of which an pt has been made to weave one definite thread Huxley expressed it some 40 years ago, ed upon purely structural considerations, and be designated a morphological classification.' wing this guide we may limit ourselves to a deration of the arrangement of living things by dy of their structure.

STRUCTURE AND FUNCTION

w the "structure" of an animal or plant con in the ordered disposition of an assemblage of ns to constitute one composite body, and it is efore obvious that any classification by struc is in reality a classification by organs or the mblage of organs. Of the work of John Hunter, ley said, "the classification which he adopted classification by organs, and that is true; but st not be lost sight of that the summation of s' constitutes 'structure.' This fact, I , has been somewhat overlooked, indeed, ey himself seems to have been inclined to re it when he said of John Hunter's system, s admirably adapted to the needs of the com tive physiologist." Looked at in the way I am vouring to present the problem Hunter's m is equally adapted to the needs of the com ive anatomist. Huxley also observed truly the unrivalled collection of John Hunter intended to illustrate the *modifications* the great physiological apparatuses undergo animal series; and here in the midst of collection it is unnecessary to remind anyone Hunter—more than any other anatomist—demonstrated that the whole form and disposition of organs is dependent on the function of the organs. We have therefore come back—as every excursion in search of truth in living economy will inevitably bring us back—to the starting-point that "structure" depends upon "function." Unfortunately, such reasoning also leads to the apparently hopeless conclusion that since classification is effected by consideration of structure, and structure is dependent on function, classification itself depends ultimately on function. It is, however, only when dealing with the simplest forms of life that the very paucity of organs in which to note differences and likenesses allows us to see that the systematist is in reality separating and grouping his material by reference to function.

It is the increasing complexity of the assemblage of organs—and that alone—that saves the museum specialist from having to make the humiliating confession that he is endeavouring, under the worst possible conditions, to arrange his specimens according to the functions which they possessed during life. Hand in hand with increasing complexity there is manifested a wonderful conservatism in the living type which admits of functional alteration of structure in one organ or system of organs, while some other system retains its ancestral and primitive condition. It therefore comes about that, functional considerations producing alterations in any one system, it is by a comprehensive study of the whole of the organs of an animal that classification is achieved. It must be apparent, however, that such a method is only to be regarded as thoroughly reliable on the assumption that no functional needs can affect a complex living thing so profoundly as to alter every part of its body in harmony. It must also be noted that it is only by the complete knowledge of the entire anatomy of any form that real certainty of its position in any scheme can be secured.

How completely function may modify such a complex thing as the structure of a mammal we do not know, but there is evidence that the completeness with which it may do so may be a pitfall to the systematist. A well-marked and peculiar specialisation—such, for instance, as the dependence upon ants as a source of food—has produced profound alterations of structure in a large number of animals. It was only precise anatomy as distinct from mere superficial examination that separated Echidna from the Myrmecophagidæ with which it was originally placed, and it is still open to question if the common habit of eating ants rather than true zoological affinity is not the real bond of some of the divergent forms grouped together as the Edentata. Again, a completely aquatic life has produced far reaching modifications of the whole body of many creatures. And though no one with any anatomical knowledge would be in danger of classifying the dugong and manatee with the whales or with the seals, still it may be doubted if the modifying effects of such a life have been properly realised in separating the Sirenia so far from the elephants and tapirs. In these instances there has been an alteration in the structure of many systems in response to the same functional need, but there are still enough organs left retaining their ancestral condition to put the true affinities of the animals beyond doubt. But it is, perhaps, not beyond the range of possibility to imagine that the modifications could become more complete and that very little indeed might retain its primitive characters.

TRENDS OF THOUGHT IN CLASSIFICATION

The *fact that functional* modifications of any one set of organs *may render* them unsuited to the purpose of universal classification has produced two definite trends in the study of living forms In the first place, it has resulted in the specialist in one restricted group selecting the characters of one set of organs for his criteria of classification, while the worker in another, and perhaps nearly allied, group arranges his material by reference to an entirely different set of organs This inconstancy of standard is apt to strike an amateur and un specialised student of nature rather than a highly trained specialist In the second place it has resulted in compelling the man who takes a more comprehensive view of living things to embark on a search for the underlying "type" which is modified, here in one direction, and there in another It is unnecessary to follow the evolution of the theory of an essential plan which, old as Plato, received a fresh stimulus from the work of Goethe, and culminated in one direction with the researches of Richard Owen and others which produced the conception of the "archetype"

These two trends of thought must be briefly noted Concerning the second, it is frankly outside the province of this paper, although it provides a most interesting study Plan—or ancestral type—of course there is, it was almost the *perfection* of the development of this idea *that brought about* its relegation to the background of scientific thought The "archetype" grew so complex that it became more a creed than a part of knowledge The criticism of Herbert Spencer decreased its vitality, the advent of the ideas of Darwin caused it to be neglected, and added to its decrepitude, and the study of embryology has reduced it to day to the position of a dead ideal of a past generation. And yet the death is no more than apparent, for its own offspring has demonstrated its vitality As Dwight has said, "*embryology*, which 50 years ago was in its infancy, confirms distinctly the view of the archetype." Even if we abandon the use of the many terms and phrases that grew up around this central idea, we must still retain the fundamental principle involved We have shifted our ground rather from the notion of an adult "unity in variety" to the conception of an embryological recapitulation

With the other tendency of efforts at classification we have, however, more direct concern.

CRITERIA OF CLASSIFICATION OF VERTEBRATES

For the moment we will pass by the organs and systems most used in the comparison of the lower forms of life and turn at once to the vertebrates, and especially the mammals with which this paper deals The most superficial examination of the methods used to determine affinities among the representatives of higher orders reveals the extent to which reliance is placed upon features of the skeleton, the teeth, and the *integument* This is, of course, *owing to the* fact that these are the parts most readily capable of preservation, and therefore most commonly available for study by the museum specialists who are responsible for most classifications Again, since place has to be found in any scheme for the material contributed by the paleontologist, it is essential that bones and teeth should be accepted as criteria of rank The question is, Are these undoubtedly convenient, and often sole available criteria, ideal ones upon which to base affinities?

The Skeleton

If we regard the skeleton, as some an have apparently regarded it, merely as a scaffolding upon which the body is built, t may feel comparatively safe in presumin similarities in the design of this scaffoldi point to relationships between the bodies o the scaffoldings were the frame work Bu regard the osseous system as a highly plasti organs, which shows a wonderful *ability t* itself, by *beautiful adjustments, to every den* stress or *strain resulting from each function* and *purpose* of the limbs and trunk, then w have doubts as to the validity of these assum Every modification of gait, every alterat muscular adaptation produces its change habits swimming, running, climbing, and b ing all—bring about modifications regard zoological affinities Even the skull is prof altered by such simple functional factors method by which food is conveyed to the Numerous instances of skeletal adaptabilit occur to every one, but one, which bridge such wide space that real confusion wou impossible, may be given The tarsometatar typical birds is an elongated bone into whic elements of tarsus and metatarsus have b fused In the penguins (Spheniscidæ), which or waddle in mammalian *fashion*, the ele are *partially* separated and the composite is short as in the mammals, in the je (Dipodinæ), which *hop* like birds, the avian portions, and even the fusion of the element present This is an extreme instance that gross *that it could* never deceive, but it shows bones adapted towards the same functional could possibly be taken as indicating zool affinities between forms which, though w separated, are members of the same order

The Teeth

It is the same with teeth, for these organs serve the all important function of dealing wit food of the animal, and, in addition, may be loped *for* killing prey, for catching prey that n no special killing, for cutting herbage, for fig rivals, as tools employed in life processes un nected with feeding, and even as organs of motion. Now, *of course*, any organ connected the feeding habits of an animal—in fact, any of the alimentary system—must be expected to in response to the nature of the food taken, and method employed in taking it A wide seri facts fulfils this expectation It is *recognised* admitted at the outset that far *more than* functional adaptations are considered in *any* cl fication by teeth, still, it is *impossible to* es the conviction that *too great a reliance* upon characters of these organs may very easily mis

The Integumentary System

With the integumentary system *it is* unnece to deal at length, it is the happy hunting gro of the systematist Colour, pattern, a few h more or less here or there, a stripe or a spot or have often been enough, as we *might* make head or a bald one, a grizzled beard, or a fre face the criteria *for* species making among kind, so has the systematist used the integume system *There is something* far more *subtle* in outer *covering* of an animal than such trea can take into account As a huge sense organ reflecting surface of the central nervous sy and as a medium for the display of everythin which the life processes of the animal demand a canvas, the skin of every living creature must be considered Among the Edentata alone we have animals with a normal hairy covering (Myrmecophagidæ), animals with coats of specialised hair (Bradypodidæ), with skins the condition of which has prompted the familiar name of "pigs" (Orycteropodidæ), with armour plates (Dasypodidæ), with protective shells (Glyptodontidæ), and with imbricated horny scales (Manidæ) In the integumentary system, again, we even have the strange fact that so conspicuous a part as the tail may become entirely lost as a normal process in functional life The aberrant porcupine (Trichys), found in Borneo, starts life with a tail, as *T guentheri*, but the female, at any rate, loses it, and ends as the tailless *T lipura*

Systems of Varying Degrees of Constancy

Passing at once from these systems which, owing to the varying ways in which the functions that they subserve may be carried out, are plastic, and ever ready to be shaped in the varying mould of habit, to those organs which possess one function carried out on constant lines, we note immediately an enormous difference

The teeth have to deal with food which may be of almost any character, obtained in almost any way, but the essential organ of sight or of hearing subserves one definite function effected in one constant way throughout the whole series of animals Animals see or hear in only one way, they feed, progress, breathe, and become protected by colour, armour, or pattern in a very great number of different ways

The constancy of the structure of the internal ear, even in widely divergent forms, has been noted by many workers, among them especially by Dr Albert Gray, the same authority has noted the greater variability of the middle ear, while the external ear is the delight of the systematist, so many are its modifications

The whole optic apparatus, including its accessory parts, is profoundly modified by function, but the essential organ of vision is so remarkably constant in its structure that though one might make a shrewd surmise that the eye belonged to an animal of diurnal, crepuscular nocturnal, or subterranean habit, it would tax the powers of the systematic zoologist to assign an excised eyeball to a member of any of the main divisions of the mammalia

It would seem, from such a point of view as I am attempting to take, that in the animal body there are systems with highly variable functions, and consequently with such highly variable characters as to form unreliable criteria for any classification other than a frankly functional one Again, it seems there are systems of such constancy of function, and consequently of such uniformity of structure, as to furnish no clues to the finer gradations of affinity such as are required for a satisfactory scheme of classification It is not likely, and it is not reasonable to expect, that there is any one system in the animal economy which would strike the mean between these two extremes and form in itself an absolute and safe standard by which to assign an animal to its proper place in the scheme of living things Yet there are undoubtedly some systems which have special claims in this direction

The brain has great title to be regarded as an organ which notes the rank of its possessor Since it is true, in a great measure, that all evolution, the whole scale of animal types, consists in an increasing perfection of the brain, it may be said that the state of the brain will indicate at once where in the scale its possessor should be placed The brain may be said to sum up in its complex structure all the functions and attributes of an animal, and increasing completeness of the knowledge of the brain would mean increasing perfection of classification The work of Elliot Smith especially has made this clear If we had to depend upon one organ only to provide all the materials for a scheme of universal classification no better choice could be made than the brain

The Reproductive System

Another system which has long seemed to me to deserve special attention in this connexion is the reproductive system, its functions are so simple, its needs for change so infrequent, and yet the changes that have been produced in it are obviously so profound The reproductive system has not by any means been passed over as a guide in classification The botanist places reliance on it, to the zoologist who deals with parasites it may furnish the most valuable guide, since even if most of the other systems of the body become reduced to mere rudiments, the reproductive system must persist in full functional development Even in the mammalia the characters of the uterus and of the placenta are commonly used to make fundamental distinctions of the greatest importance "So far back as the year 1816 M de Blainville pointed out that the mammalia might be divided into three primary groups, according to the character of their reproductive organs, especially the reproductive organs of the female" It is from this work of M de Blainville that we have inherited the divisions of ornithodelphia, didelphia, and monodelphia

Classification by placental characters does not so directly concern us here, but Huxley has recorded his opinion of the taxonomic value of this structure in the most emphatic terms "It appears to me that the features of the placenta afford by far the best characters which have yet been proposed for classifying the monodelphous mammalia" The study of these portions of the reproductive system has therefore already yielded important results for the systematist, but I do not think that the taxonomic value of the system is exhausted by the study of these two characters In most instances it is practically certain that a complete study of the fœtal and adult genitalia of any debated candidate for classification would clear up all doubts as to its real systematic position

A detailed study of the development and the adult condition of the genitalia of the whole mammalian series is obviously a stupendous task and one that is limited at every turn by the lack of suitable material It has therefore been my aim to examine a series of types of which sufficient material could be got together, and to attempt to determine any principle which underlay the modifications that were met with Put quite briefly, it has been forced upon me that two very different tendencies are seen in the modifications of this system (1) the marked conservatism of the type upon which the genital system is formed, and (2) the complete transformations of which it is capable in functional emergencies These tendencies which at first sight seem to be opposed need some explanation and it is necessary to follow, briefly the modifications of the genital system up to the point at which we commence its detailed study in the mammalia

MODIFICATIONS OF THE GENITAL SYSTEM IN VERTEBRATES

We may take as a simple type of vertebrate genitalia, a system which consists, in both sexes, of bilateral genital glands, which may or may not shed their products into the cœlom, but which ultimately pass these products to the cloaca, and so to the exterior, by ducts which are primarily bilateral Such a system is found, with only minor modifications, throughout the fishes and amphibians, and, functionally, we may say that such a system is found where the ovum is extruded as a more or less gelatinous mass either into water or into some damp place It is the simplicity of the female genital products, extruded under such circumstances, that has served to retain the simplicity of the genital system. As long as a soft gelatinous ovum is extruded into water so long may the spermatozoon penetrate its envelope and effect fertilisation after extrusion External fertilisation, therefore, merely requires a system of genital glands and excretory genital ducts by which the genital products may escape to the exterior, and meeting in the surrounding medium insure fertilisation But such a genital system will only suffice for aquatic animals, or animals which are aquatic or semi aquatic during their breeding season, for an egg, so delicate that a spermatozoon may penetrate it, is far too perishable an object to be extruded in ordinary circumstances into the open air

When an animal becomes completely terrestrial in habit it is essential that the extruded egg cell should have some protective covering to insure it against destruction by the ordinary agencies that come into play in terrestrial life It is the addition of this protective covering that produces such great primary changes in the genital system, for the protective covering prohibits the entry of the spermatozoon after the extrusion of the ovum, and internal fertilisation becomes a necessity This is the first great modification brought about in the genital system—a modification due to the alteration of life habit

The vertebrates which first became, in part, independent of their aquatic environment still retained their ancestral habit of laying unprotected eggs, and this being so it was necessary for them to return to the water during the period when they were laying their eggs It is the breeding season, and that alone, that kept, and keeps, the amphibia in touch with their ancestral environment Some few have solved the problem by retaining the ovum within the genital passages until some degree of development has taken place (*Salamandra atra*, *Caecilia compressicauda*, &c) Such forms must effect internal fertilisation in some way, and the modifications that have taken place especially in Caecilia among the Gymnophiona are of peculiar interest and will need future reference

Other aquatic animals that have attempted to colonise the land have encountered the same disabilities, and here we may note, as we shall repeatedly have occasion to do, parallel developments in the invertebrates Among the Isopoda, *Birgus latro* has become apparently a purely terrestrial form, and yet though its whole body is admirably adapted to its new life, its ancestral habit is retained, and once a year it has to return to deposit its eggs in the element from which it has so successfully emancipated itself in all other respects A whole series of crabs showing intermediate stages of terrestrial adaptations exists, and in other invertebrate orders [illegible] could readily be multiplied

Of the vertebrate stock it is the reptiles as a class that first become so completely terrestrial as to be able to deposit eggs on land Even those members of the class that lead aquatic lives return to the land to lay their eggs The factor which permits this complete reversal of habit is the addition of the protective covering—the membranous or calcareous egg shell—to the ovum to enable it to withstand the desiccating influences of subaerial incubation But since this protective membrane is laid down in the female genital passages it is essential that the spermatozoon should reach the ovum when still within the passages and before the protective membrane is deposited With this functional change great structural alterations must be brought about, for the male must evolve some means for injecting the spermatozoa into the female genital passages, and the female passages must be modified for the reception of this

Changes in Structure to Secure Internal Fertilisation

We may see the initiation of these changes in non terrestrial forms, for the elasmobranchs, though thoroughly aquatic, have found it necessary to lay protected eggs (the familiar "mermaid's purses') or even to retain the ovum and embryo during certain phases of development within the maternal genital passages In them fertilisation must of necessity be internal. In response to this need the male fish has developed the "claspers" (though the name is by no means a good one) for insertion into the female cloaca. By these claspers or seminal guides the spermatozoa are conducted from the male cloaca into the female cloaca and genital ducts, and internal fertilisation is effected This seminal guide becomes the functional type of the male copulatory organ of the higher terrestrial vertebrates

We have a parallel evolution among the invertebrates, many of which lay protected eggs and have to secure internal fertilisation Among the Insecta, the development of copulatory organs has reached a high state of perfection, and it is to be noted that in many orders these organs have provided the systematist with very satisfactory guides for classification In the invertebrata again the production of living offspring has been adopted in many forms

Although analogous structures, the claspers of the elasmobranchs are morphologically quite distinct from the copulatory organs of the mammals The first hint of the mammalian condition is afforded in the Gymnophiona and in Salamandra among the Amphibia This fact has been noted by Gegenbaur, who says "Un indice d'un organe copulateur se remarque chez les amphibiens (*Salamandrines*) sous la forme d'une papille faisant saille dans la cloaque' Gymnophiona has long been recognised as an amphibian which everts a portion of its cloacal wall as a copulatory organ which is some 5 centimetres long

In the most generalised of the Reptilia (Sphenodon) no definite copulatory organ is developed, and doubtless some everted portion of the cloacal wall suffices as an intromittent organ But in all other reptiles a specialised copulatory organ is present

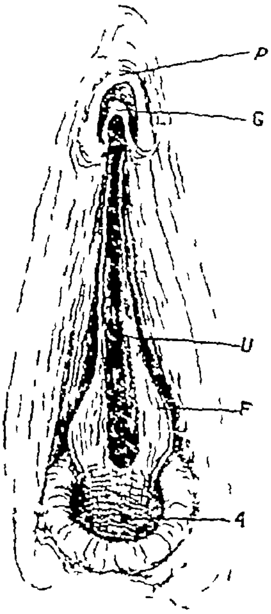
Reptilian Types of Organs

It is of the utmost importance to note that tw distinct types of copulatory organs are developed ar the reptiles The first type concerns us mos directly, since it is so obviously a stage that i in advance of that shown in the Gymnophiona or in Sphenodon, and yet is so easily interpreted as being a stage that is but little behind that seen in the monotremes, or in the more primitive insectivores among the mammals This is the type of copulatory organ developed in the chelonians and crocodiles (See Fig 1.) The second type—that belonging to the snakes and lizards—we may dismiss from this inquiry with a brief statement of its general condition Copulatory organs of this type consist of paired eversible sacs, each furrowed by a seminal groove, which are devoid of cavernous tissue and which are not developed within the cloaca They are extremely reminiscent in some ways of the claspers of the elasmobranchs and are difficult or impossible to homologise with the copulatory organs of the mammals

The genitalia of the chelonians and crocodiles, however, need careful study, since they seem so patently to carry on the process which, initiated in the gymnophiona, culminates in the mammalian condition (See Figs 1, 2, and 3)

The marine chelonians possess an intromittent organ that is far more highly developed than anything seen in the amphibians Specialisation of the ventral wall of the cloaca has resulted in the production of an erectile thickening which is marked by a median groove—the seminal groove—which runs from the cloacal orifice of the uro genital sinus almost to the distal end of the erectile body In some forms this ventral erectile mass becomes raised from the cloacal wall, and altogether free of it at its most caudal limit, and a projecting penis, grooved on its dorsal aspect, is produced In many tortoises this intracloacal penis becomes further developed The distal portion which is free of the cloacal wall becomes longer and at the same time specialised and prominent lips are developed along the sides of the seminal groove

FIG 1

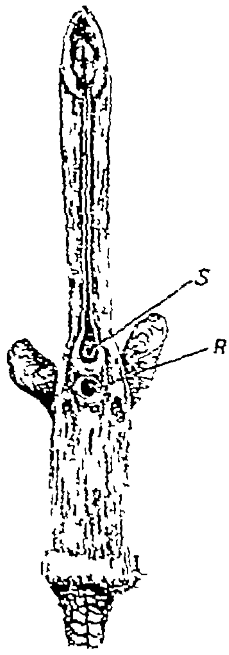


The penis of *Testudo elephantina* freed from its connexions with the cloacal wall In the male of this species the "seminal guides" pass within the anal margin P Fold over terminal portion (*prepuce*) G Terminal portion (glans) U Seminal groove (penile urethra) F Seminal guides (inner genital folds) A Anus (From a specimen in the Museum of the Royal College of Surgeons of England)

FIG 2

U Seminal groove P Penis F Seminal guides. S Uro-genital sinus R Rectum (From a specimen in the Museum of the Royal College of Surgeons of England)

FIG 3



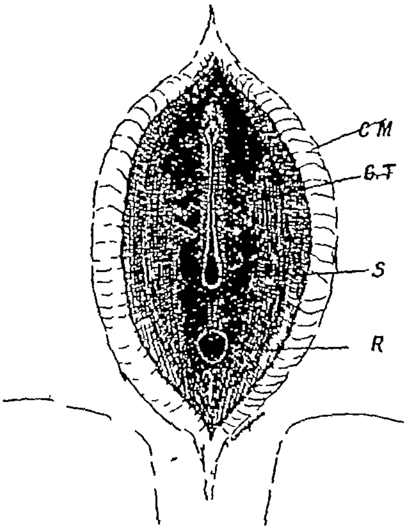
Penis of a species of *Emys* The cloaca has been split into an anterior and a posterior portion by incisions along its lateral margins and the anterior wall (penis) turned upwards S Orifice of uro-genital sinus R Orifice of rectum

The condition present in these reptilian types is singularly like that seen in some of the least specialised birds; for the Ratitæ possess copulatory organs obviously akin to those described, and other avian orders show rudiments or modifications of this condition The perfection of this reptilian copulatory organ is seen in some of the larger tortoises, such as *Testudo elephantina* (Fig 1) In these animals the organ is extremely large, and indeed in all the tortoises the mechanical difficulties imposed by the rigid carapace appear to be the functional cause of the great development of the penis The cloacal orifice is a transverse slit situated at the root of the tail, and in the ordinary quiescent condition the copulatory organ is entirely hidden within the cloaca, but even in these circumstances a very slight eversion of the cloacal margins reveals the free extremity of the penis in the male In the female the whole structure is considerably reduced

Comparison of Mammalian with Reptilian Organs

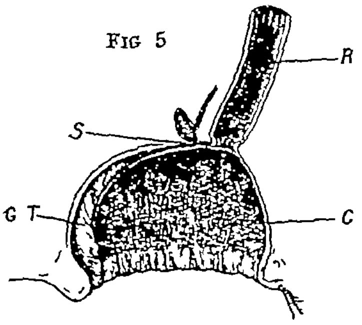
In the copulatory organs of these animals all the essential parts of the mammalian external genitalia may be recognised The penis stretches from the uro genital sinus orifice to its free tip just within the cloacal margin, and the proximal portion of its erectile tissue obtains a skeletal fixation point on the pelvic girdle within the carapace It is obviously strictly comparable with the whole of the erectile mass of the mammalian penis Its dorsal surface is marked with a groove—the seminal groove—which is continuous with the uro genital sinus orifice and runs towards the free extremity of the penis, but comes to an end some little distance short of that extremity Along the margins of this groove bilateral free folds are developed, these are sometimes termed the plicæ recto urethrales, but seminal guides is the best name that we can give them at this stage These folds terminate towards the tip of the penis at the point at which the *groove* ceases, towards the root of the penis they become more prominent and, skirting the sides of the uro genital sinus, they disappear within the margins of the anus or meet slightly in front of the anus The free tip of the penis shows several interesting features The seminal groove and its ridges end at a spongy swollen mass of tissue which is distinctly marked off from the rest of the body of the penis by a deep groove which surrounds its lateral and distal aspects The free tip of the penis distal to the surrounding groove is a narrow margin of tissue which may be said to constitute a hood encircling the spongy erectile mass in which the seminal groove ends This terminal hood I imagine may be taken as the chelonian representative of the human prepuce, and in harmony with this the distal spongy mass appears to be the equivalent of the human glans The seminal groove becomes the penile aspect of the human urethra and the fused seminal guides constitute its floor In the female these structures are reduced as a whole, the seminal guides are not so well developed, and it is to be noted that, as a rule, they do not extend further back than the orifice of the uro genital sinus The copulatory organ is smaller in the female and the seminal groove is not so deep as in the male

FIG 4



The cloaca of a chelonian opened to show the cloacal roof and the intracloacal genital tubercle *in situ* (semi-diagrammatic) C M Cloacal margin G T, Genital tubercle S Uro-genital sinus R, Rectum.

FIG 5

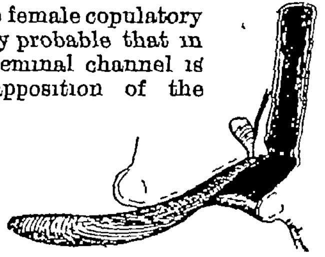


The chelonian cloaca seen from the left side in section The penis is in the quiescent intracloacal condition The products of the uro-genital sinus in this state are shed into the cloaca R Rectum C Cloaca S Uro-genital sinus G T Genital tubercle

Of the functional significance of the parts there can be no doubt The erectile copulatory organ of the male is protruded and everted from the cloaca, and in this action the seminal guides tend to close over the deepened seminal groove and to convert what is, in the unerected condition, a mere depression, into a complete tunnel. As the male copulatory organ is passed into the female cloaca it comes into contact with the dorsal aspect of the female copulatory organ, and it is highly probable that in these creatures the seminal channel is completed by the apposition of the seminal groove and guides of the male with those of the female

In the ordinary quiescent condition of the parts the products from the male uro genital sinus merely pass out of the orifice of that chamber into the cloaca, and so to the exterior (Fig 5) In this special act it is necessary that they should be conveyed into the corresponding orifice of the female, and this is effected by the closure of the male seminal guides, possibly assisted by those of the female (Fig 6)

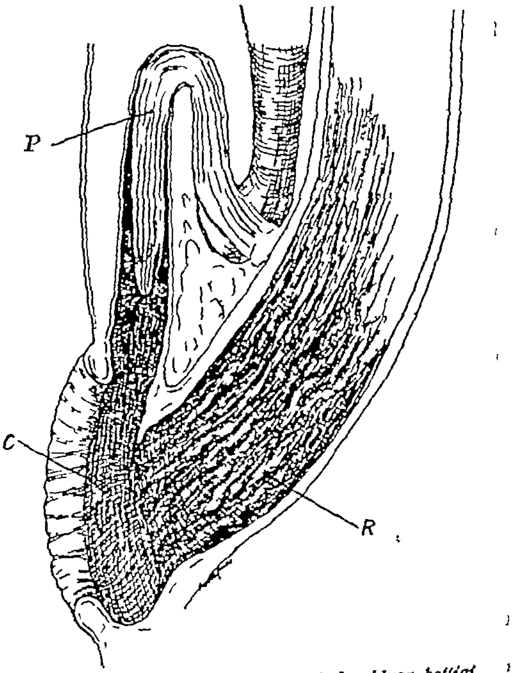
FIG 6



Chelonian cloaca seen from the left side in section The penis in the functional extroverted condition The seminal guides now meet and convey the products from the uro-genital sinus to the end of the penis.

Now, between this stage and the condition seen in the Monotremes there is no very wide difference, nor for that matter is there any very sudden transition to the type of cloacal genitalia of some of the Insectivora Speaking broadly the advance made consists of the closing over and meeting of the seminal guides in the male, so that the seminal groove is closed in whole (Insectivora) or in part (Echidna), but the cloaca

FIG 7



A reconstructed section of the cloaca of *Crocidura bottigi* (shrew from Abyssinia) showing the intracloacal penis P Penis C Cloaca R Rectum still exists, and in the quiescent state the external genitalia are still retained within the cloaca.

In Echidna the intracloacal genital tubercle of the male presents a completed penile channel in distal portion, but at its proximal end the seminal guides have not completely united over the seminal groove and a state of normal hypospadias exists at the root of the penis, this deficiency being obliterated with erection of the organ In the cloacal Insectivora, such as *Blarina* and *Crocidura*, the closure of the seminal canal is completed in the male, and the hypospadic condition of Echidna is lost (Fig 7)

We have therefore in some of the mammalian orders a retention of a cloacal condition, and in these an advance has been made on the chelonian condition mainly by the closing in of the seminal groove In the cloacal Insectivora the penis has reached a high degree of development and is usually remarkable for its great length, so much so that it is retained, more or less coiled, in a diverticulum of the ventral part of the cloaca. It is very important to recognise that the cloacal condition *does* exist among the Insectivora, and I have come to think that the appreciation of the differences to be detected in the methods of formation of the external genitalia within the limits of this group forms a basis for a better understanding of the inter relations of the other mammalian groups To this point it will be necessary to revert later on. It is equally important to recognise that the chelonian condition is not only practically identical with the lowest mammalian type of external genitalia, but it is also represented as an early stage in the embryonic development of the external genitalia of all mammals From a simple stage in which an intracloacal genital tubercle, bearing a seminal groove marked laterally by seminal guides, is present, the adult external genitalia of all mammalian orders are derived, but the method of derivation and the final condition produced present very striking differences, first, within the limits of the group Insectivora, and second, within the whole compass of the mammalia It is necessary to describe the stages of the development from this simple condition as they are displayed in various mammalian embryos

I have come to believe that there are two main types of development and two main types of resulting external genitalia, that all mammals may be placed in the one group or the other, and that an examination of the adult genitalia will generally, and an examination of the embryonic stages will always, reveal definitely into which group a particular species falls

---

A POST-GRADUATE COURSE IN VENEREAL DISEASES.—A special course of lectures and demonstrations for post graduate and advanced students will be given at St Mary's Hospital on Mondays and Thursdays at 4 P M, beginning April 27th and ending July 2nd Dr Sidney P Phillips will deal with syphilis of the abdominal viscera, Mr J Ernest Lane with the treatment of venereal diseases and syphilis of the tongue, Dr Wilfred Harris with syphilis of the nervous system and parasyphilis Dr W J Gow with syphilis in relation to obstetrics and gynæcology Dr E G Graham Little with syphilis and the skin, Mr A Fleming with the biological and laboratory aspects of syphilis and Mr Leslie J Paton with the ophthalmology of syphilis Applications for admission to the course, for which the fee is 4 guineas should be made to the school secretary a reduction being made in the case of former St Mary's men

AN ANALYSIS OF THE PROBLEM OF THE MINIMAL LETHAL DOSE AND ITS RELATIONSHIP TO THE TIME FACTOR *

BY GEORGES DREYER, M D,

AND

E W AINLEY WALKER, D M OXON

(*From the Department of Pathology, University of Oxford*)

IN a previous paper[1] evidence has been brought forward to show that over a wide range of weight in any given species animals of different size can readily be employed for the standardisation of toxic substances and antitoxins, instead of animals of an arbitrarily selected weight as has hitherto been necessary All that is required is that the doses given shall be calculated in relation to the body surface and blood volume of the individual animals employed For this purpose we have suggested the use of the formula $D = \frac{d}{W^{0\,72}}$, where D represents the dose in relation to the surface of the individual, W is the weight of the animal, and *d* is the actual quantity of drug administered From this formula one calculates with equal readiness the "surface dose" † (D) for any actual quantity of drug (*d*) administered, or the quantity (*d*) of drug which must be given in order to produce a dosage (D) in relation to the surface of the individual animal concerned But in the standardisation of toxins, antitoxins, and drugs by means of animal experiment another factor of the greatest importance comes into play—namely, the time to death. Accordingly, it has hitherto been the accepted custom not only to employ animals of an arbitrarily selected weight, but also to fix upon an arbitrary time to death as a means of rendering such experiments comparable *inter se* This method, the only accurate one hitherto available, we owe to the pioneer work of Ehrlich, which has been fundamental for the study of the problems involved in the phenomena of protection and the action of toxins But how far this method of comparison actually falls short of affording a true measure of relative toxicity will appear from the following considerations, which in our opinion have long demanded a detailed investigation

First, if one takes two samples of diphtheria toxin and determines the dose of each toxin which will kill a guinea pig of standard weight in standard time (and would therefore be considered equivalent doses), it is found that equal multiples or submultiples of these doses are no longer equivalent in their action in the animal body Accordingly, the equivalence thus determined is merely a coincidence, and not in any sense a real equivalence, since if any other lethal times be chosen the equivalent doses experimentally determined will be found to have an entirely different ratio to each other

Thus, taking two samples of diphtheria toxin, we arrive at the following results for the equivalent doses at different times:—

---

* A more detailed account of this work is published in the Biochemi che Zeitschrift 1914 vol lx p 112.

† Dose calculated in relation to body surface (and blood volume)

TABLE I.—*Showing Comparative Strengths of Diphtheria Toxins (B) and (C)*

To kill a guinea pig of 250 grm in hours	Toxin B Dose in relation to surface × 10^7 in c.cm.	Toxin C Dose in relation to surface × 10^7 in c.cm.	Ratio between equivalent doses $= \frac{\text{Dose of B}}{\text{Dose of C}}$
36	3519	3233	1·09
48	2860	2241	1·28
60	2632	1867	1·41
72	2522	1672	1·51
96	2413	1472	1·64
120	2359	1366	1·73
144	2327	1303	1·79

It will at once be seen that the ratio of the equivalent doses of the two toxins increases steadily as the time to death is increased. Thus, when the standard time for death—namely, 96 hours—is taken, the equivalent dose of toxin B is about 65 per cent. greater than that of toxin C. But if 36 hours is selected as the lethal time the equivalent dose of toxin B is only about 9 per cent. greater than than of toxin C, while if 6 days is taken as the death time, the dose of toxin B is approximately 80 per cent. larger than that of toxin C.

Again, if instead of comparing the effect of two different samples of toxin on a given species we take the observations of Wolfgang Ostwald and Dernoscheck[2] on the small crustacean Gammarus poisoned by immersion in sea water of varying *concentration*, and thus compare the effect of one and the same toxic substance on the male and female animal respectively, we find the following results:—

TABLE II.—*From Wo. Ostwald's Observations on Gammarus*

Concentration of sea water in °/oo	Time to death in the male animal in minutes	Time to death in the female animal in minutes	Ratio between death times $\frac{♂}{♀}$
58·7	36	36	1·00
47·2	48	46	1·04
40·1	79	53	1·49
35·4	120	77	1·56
33·0	147	86	1·71
28·3	326	185	1·76
25·9	lives	328	∞

Table II. thus shows that for the same concentration of the toxic fluid the ratio between the lethal times for the two sexes steadily increases as the concentration of the toxin is diminished. Thus, with a concentration of 58·7 the time to death is the same in the two sexes while with a concentration of 40·1 it takes about 50 per cent. longer to kill the male than the female, and with a concentration of 28·3 over 75 per cent. longer.

Accordingly, whether we take times to death in a given species of animal, and compare the equivalent doses of two toxins which will kill in these times, or take different concentrations of one and the same toxin and compare the times to death in male and female animals of the same species, we find that the standard method hitherto employed cannot afford a true measure of relative toxicity. This conclusion necessarily follows from the fact that with different death times the ratio between the equivalent doses of the toxins is found to vary, and with different concentrations of the toxic fluid the ratio between death times is also found to vary. As these respective variations are extremely marked it is evident that the point requires no further elaboration.

It follows that a method of calculation must be sought by means of which toxicity can be estimated quite independently of any arbitrarily selected death time or any particular dosage chosen from comparison. After a prolonged consideration of a large mass of material one of us (G. D.) arrived at the following formula for the relationship between concentration and quantity of dose and the time required to cause death (or to produce any other desired effect in animals of any given species)—namely, $\frac{1}{D_0 - a} - \frac{1}{D_1 - a} = k\,(T_0 - T_1)$, where D_0 and D_1 are "surface doses" (doses expressed in relation to body surface corresponding to the times T_0 and T_1, in which the death of the animal (or other desired effect) is produced, a is a figure the value of which is dependent both on the particular species of animal employed and the particular toxin, and k is a constant to be determined for the particular toxin and the particular species of animal employed. Expressed in words, the formula simply states that *to every equal increment in time there corresponds a definite decrease in the active dose* $(D - a)$.

This formula we have tested over a very extensive series of observations of the most diverse character, and find that it affords an extremely satisfactory method of calculation. As will be shown below, it allows equal significance to be placed on each individual observation in a long series of animals of different weights, entirely independent of the dose and death time.

Before proceeding further it is now desirable to consider briefly the quantity a. In determining the minimal lethal dose of any toxic substance (or the dose required to produce any given effect) one arrives, by gradually diminishing the dosage, at a quantity less than the critical dose in question, which appears to be inactive. The animal does not die, or the other desired effect, whatever it may be, is not obtained. How closely the size of a, as determined by our method, approaches the size of the minimal effective dose (M.L.D. or other) depends not only on the character of the particular substance under investigation, but also on the character of the effect desired—whether this be death or any other manifestation of toxic action. But to the precise meaning of a we shall return.

The importance of discovering the relation between the concentration or quantity of dosage and the corresponding time to death has been fully realised by several of previous workers, and especially by Arrhenius,[3] Warren,[4] Wolfgang Ostwald,[5] and Ostwald and Dernoscheck.[2] Of these, Warren, Ostwald, and Ostwald and Dernoscheck suggest definite formulæ for the case of small crustaceans poisoned by immersion in solutions of various salts.

Warren's formula is $\frac{1}{T} = k\,(c - n)$, where T is the time to death, c the concentration of the salt solution, n a number constantly subtracted from c, and k a constant. This formula states that the time to death is inversely proportional to the concentration diminished by n But this is not the case

Ostwald and Dernoscheck's formula is $\frac{1}{T} = k\,(c-n)^m$, and it is clearly a generalisation of Warren's formula (which they criticise), obtained by the introduction of a varying power m instead of the power 1 This formula they substitute for Ostwald's original formula $\frac{1}{T} = k\,c^m$, in recalculating his observation on Gammarus They show how much more satisfactory is the agreement between observed and calculated figures when this formula is used instead of Warren's formula or even Ostwald's own earlier formula

As regards the significance of n Warren appears to consider it to represent the concentration of salt *normal* to the animal observed (Daphnia), while Ostwald and Dernoscheck arrive at its value by a process of calculation It does not, however, appear that the latter observers attach any rational significance to the meaning of n in their formula

One of us (E W A W) in 1901,[6] in attempting to clear up the difficulty which obtained regarding the relation between the amount of antitoxin or antibody required to neutralise one M L D in the body of an animal, and the amounts required to neutralise multiples of the M L D showed that a certain non effective dose (a) must always be subtracted in calculating the amount of antitoxin required As, however, no attention was then given to the time factor, the results obtained by administering doses on this system only held good over a quite short range of multiples of the M L D But in the formula devised by the other of us (G D) the value of (a) is made to be dependent on the *rate of killing*, and not merely on the fact that death does or does not occur

We now proceed to show how successfully this formula may be applied, not only to our own experimental results, but also to a mass of diverse published observations In all the cases which we have examined where a sufficient range and number of observations is provided to afford a material suitable for calculation the formula holds good, and represents the experimental findings in an extremely satisfactory manner

In Table III is given a series of our own experiments with a diphtheria toxin (B) The doses (D) are given as calculated in relation to surface by the formula $D = \frac{d}{W^{0.72}}$ where W is the weight of the animal in grammes, and d is the *actual dose* administered

The results in Table III show clearly that the formula proposed represents the experimental data for the grouped experiments in a very satisfactory manner Although the animals employed cover a range of weight from 200 grm to 530 grm, the difference between the death times calculated by the formula and those actually observed averages only 0 38 per cent Similar results were obtained for two other samples of diphtheria toxin (A) and (C) In the case of toxin (A) it was found that $k \times 10^7 = 330$ and $a = 1140$, while for toxin (C) $k \times 10^7 = 316$ and $a = 1045$ For toxin (A) the average death times ranged from 85 to 220 hours, and for toxin (C) from 67 to 148 hours

But as has already been pointed out above, it is impossible to draw any reliable conclusion regarding the actual strengths of the three samples of diphtheria toxin A, B, and C from a comparison of the doses required to cause death in any given fixed time, for, as already stated, their ratios to one another vary for each particular time A measure of relative strength can, however, be obtained by comparing the size of the three different constants k, which are dependent on the size of the effective doses of the toxins These constants vary in this sense, that in toxic substances of the same quality the weaker toxin has a larger k in the formula while the stronger toxin has a smaller value for k This comparison is the only one that can be obtained, which is independent, not only of the weight of the animal (in any given species), and of the dosage, but also of the time factor It gives an expression for the relative strengths of the three samples of toxin These are related to each other as k_A k_B k_C Expressing the facts in words, one is able to say that if we have two samples of toxin P and Q where—for example, two diphtheria toxins P and Q where the value of k for P is the *double* of that for Q—then for each given increment of time the *increase* in the reciprocal of the effective dose in the case of P will be the double of the *increase* in the reciprocal of the effective dose in the case of Q The effective dose is given in each case by the expression $(D - a)$

In regard to the significance of a in the formula this quantity represents the 'non effective' portion of the dose—that is to say, the dose which in itself

is insufficient to cause death (or other desired effect) Accordingly, its size varies with the resistance of the sex and species, being larger for the more resistant type and smaller for the more susceptible Further, with one and the same toxic substance, *a* is greater the less the toxicity of the particular sample which is employed Thus, in the case of the three samples of diphtheria toxin dealt with above it was found that for C, the most active toxin, *a* had a value of 1045, while for A, which was somewhat less active, it was 1140, and for B, much the weakest sample, it was 2200

In Table IV is given an analysis of experiments by W H Schultz[9] with a synthetic adrenalin (ethyl amino aceto catechol) in the mouse. Twenty five experiments done about the same time (Jan. 5th and 16th, 1909) on animals not previously injected with the drug are taken from his series (his Table XIV) The observations were made on mice varying in weight from about 12 grm. to 25 grm After they had been arranged in order according to "surface dosage" they were collected into five groups by averaging the "surface doses" and lethal times From these data the constant *k* was determined, and by its use the theoretical time to death was calculated for each group It was found that the average difference between the calculated and the observed lethal times was only 2 68 per cent From this it follows that the formula proposed also applies very satisfactorily to the case of synthetic adrenalin, where the death times are extremely short (minutes), as contrasted with the long death times (up to several days) with diphtheria toxins

The value of employing the method of calculation here brought forward is well illustrated by comparing the observations of Madsen and Noguchi[10] on filtered and unfiltered samples of cobra venom. As already pointed out, it takes account not only of the size and surface area of the animal concerned, but also of the time required to produce the desired effect (e g, death), while at the same time it gives results which can be applied (within a given species) quite independently both of lethal time and of the size of the individual animal employed

Madsen and Noguchi came to the conclusion from their experiments with *cobra venom* that the toxicity of the venom was not sensibly diminished by filtration through a Chamberland filter This result contrasted strongly with their further observation, that after similar filtration *crotalus venom* was diminished in toxicity by as much as 50 per cent The data for cobra venom (from their Tables XIX. and XXIX) were, therefore, calculated by our formula For the unfiltered venom *k* was found to be 110 and *a* 185, while for the filtered venom *k* was 130 and *a* 270 These results show that the toxicity of the cobra venom was in reality greatly reduced by the process of filtration, since the "surface dose" of filtered venom which is needed to kill a guinea pig with certainty is much greater than the surface dose required for unfiltered venom.

In view of the evidence which has now been given it is unnecessary to adduce further detailed calculations of experiments in support of the method and formula here proposed for dealing with questions of dosage and toxicity But it should be mentioned that the formula is in excellent accord with all the published observations which we have analysed where an adequate series of data is available Among the observations which we have examined from this point of view and which we find to fit the formula are the following Knorr's experiments with tetanus toxin injected subcutaneously in the mouse[11], Elliott, Sillar, and Carmichael's experiments with krait venom injected subcutaneously in rabbits[12], Fraser and Elliott's experiments with the venom of Enhydrina valakadien injected subcutaneously in rabbits[13], natural adrenalin in the mouse, Schultz[9], sulphate of physostigmia subcutaneously in rabbits, Fraser[14], caffeine subcutaneously in guinea-pigs and cats, Salant and Rieger[15], cobalt nitrate subcutaneously in guinea-pigs, Bock[16], and potassium chloride injected intravenously in rabbits, Hald[17]

From these facts we conclude that so far as evidence at present goes the formula is one of general application in regard to dosage and death time in warm blooded animals That it holds not only in regard to lethal effects but also in the case of ordinary pharmacological and toxic action in general is seen from the experiments of Schultz[9] on the mydriatic action of synthetic adrenalin in the excised frog's eye These experiments are analysed and calculated below in Table V, where it is seen that the percentage differences between Schultz s observed times and the times calculated by our formula are in every case but one very small indeed, and even taking in the one obviously divergent figure give an average error of only 2 73 per cent

TABLE V—*Mydriatic Action of Synthetic Adrenalin on the Excised Frog's Eye (Schultz s Experiments)*

$$\frac{1}{D_0 - a} - \frac{1}{D_1 - a} = k(T_0 - T_1) \; - k \times 10^4 = 805, \; a = 2\ 2,$$

$$(T_0 = 20, \; D_0 = 500)$$

Group (Schultz)	D = relative dose—i e concentration of the solution employed.	Time to maximum mydriatic effect = T observed minutes	Time to maximum mydriatic effect calculated = T calculated minutes	Percentage difference between T calculated and T observed
1	1000	21	18 8	11 70

One further example of the application of the formula may be given in a case where the animal

Standardisation in the ordinary hæmocytometer chamber 0 1 mm deep—The vaccines were standardised before sterilisation in case the heating for half an hour at 60° C produced agglutination. The optically plane polished coverslip supplied with the apparatus is too thick for use with an oil immersion, or even with most types of 1/6th inch dry lenses Leith Murray in 1908 to remedy this defect suggested using a thin coverslip chosen from those supplied for ordinary microscopical work in the following manner "A series of slips is cleaned and applied successively to the cleaned and dried plate glass slip provided with the apparatus after breathing on the opposing face of each Pressure is applied to make them adhere, and the slips which show Newton's rings well distributed over the surface are selected for use" This ingenious method, however, is not satisfactory if scientific accuracy is demanded Many oil immersion lenses depress such a coverslip and consequently diminish the depth of the counting chamber, thus a No 2 coverslip of about 0 17 mm is too thick for an ordinary 1/12th achromatic oil immersion lens supplied by Leitz, Swift, or Beck with a free working distance of 0 17 mm, while even a No 1 coverslip of about 0 12 mm is too thick for an achromatic 1/12th supplied by Zeiss or Bausch and Lomb with a free working distance of 0 15 mm

The pressure of the lens upon the coverslip can easily be demonstrated by the to and fro movement of the bacteria in the counting chamber which occurs with slight alteration in the fine adjustment Even if the lens does not actually touch the cover slip, alterations in the fine adjustment may cause movement of the bacteria in the counting chamber from suction or adhesion between the two surfaces owing to the immersion oil. This suction effect may be very marked with thick oil and certain types of lens mount It can easily be demonstrated in another way by taking an ordinary microscope slide, placing a drop of oil in the middle, and pressing the lens down gently till it almost touches the glass If the lens is quickly raised the slide will be lifted with it This suction action can be diminished if very thin immersion oil is employed.

Another point may be alluded to Even if a thin coverslip of 0 15 mm. or less does give Newton's rings in some part when pressed down upon a moistened glass plate, it by no means follows that the surface is mathematically plane when a large portion forms the roof of a counting chamber The elasticity or want of rigidity of such a coverslip, when in position over the filled chamber may be easily appreciated by making a very gentle pressure upon its centre with the point of a pencil This will cause the fluid to bulge over the edge of the chamber No one would think of using an ordinary microscopical cover slip which is neither rigid nor optically plane for enumerating red blood corpuscles or leucocytes, why, then, should it be employed for the standardisation of bacterial vaccines when accuracy is of even more importance? Zeiss manufacture an optically plane cover glass for counting chambers of 0 18 mm thick, strengthened with a "cemented cylindrical glass cell." "The lower side of this cover glass is polished accurately plane" This slip gives Newton's rings without difficulty We have found, however, by actual experiment that it is too thick for all ordinary oil immersion lenses when used with a hæmocytometer chamber 0 1 mm deep In order to understand the reason of this it is necessary to discuss the free working distance of an oil immersion lens

Free working distance—Zeiss[5] has defined the free working distance "as the distance between upper surface of a cover glass 0 17 mm thick and the lower surface of the lens mount, the lens being sharply focussed for an object situated immediately below the cover glass" The free working distance of a Zeiss achromatic 1/12th oil immersion lens when oil is employed is stated to be 0 15 mm, thus the "actual distance" *between the metal* mount of the front lens and the object is 0 32 mm Fig 1 shows that a lens with a free working distance of 0 1 has an actual distance of 0 27 It is important to note, however, that these figures are approximate because the "metal mount of a front lens is necessarily subject to unavoidable slight variations" (Zeiss[5]) The free working distances of a 1/12th oil immersion achromatic objective supplied by other makers are as follows Ross, 0 15 mm, Swift, 0 17mm, Watson, 0 17 mm, Baker, 0 17 mm, Leitz, 0 17 mm, Reichert, 0 15 mm., Bausch and Lomb, 0 15 mm, Zeiss, 0 15 mm. The free working distance of many apochromatics is frequently much less than 0 15 but apart from their expensiveness they are hardly suitable for such work as the standardisation of vaccines owing to the greater care required in using them Leitz manufacture a 1/12th oil-immersion fluorite objective 1 32 N.A, and Watson a 1/12th with a free distance of 0 12 and 0 09 mm respectively

These figures indicate at first sight that the free working distance of the ordinary 1/12th immersion lens likely to be used in the laboratories with the exception of the special lenses made by Leitz and Watson is theoretically never less than 0 15 mm Unfortunately, we found by actual experience when working with coverslips of known thickness that the free working distance of many lenses is in reality very much less than stated in the catalogues Thus a well known firm tested one of their own new lenses with a reputed free working distance of 0 17 and found it only 0 10, while a lens by another maker stated to be 0 15 was only 0 08 The free

IMPROVED METHODS OF STANDARDISING BACTERIAL VACCINES IN HÆMOCYTOMETER CHAMBERS[1]

BY ERNEST E GLYNN, M A., M D CANTAB, F R C P LOND,
ROFESSOR OF PATHOLOGY UNIVERSITY OF LIVERPOOL BACTERIOLOGIST AND PATHOLOGIST TO THE ROYAL INFIRMARY, LIVERPOOL
AND
A ARMSTRONG REES, M D, B Ch Liverp, M R C S Eng, Formerly Thelwall Thomas Fellow, MILDRED POWELL, M D Liverp, Formerly John Garrett Fellow, and G LISSANT COX, M A, M D Cantab, Senior Tuberculosis Officer, Lancashire
(*From the Thompson Yates Laboratories, University of Liverpool*)

THE simplest scientific method of standardising bacterial vaccines is the direct enumeration of the bacteria in some form of hæmocytometer chamber It was first suggested in 1908 by Mallory and Homer Wright,[2] who employed a well 0 02 mm deep, an optically plane coverslip, a 1/6 inch dry lens, and no staining fluid, also by Leith Murray[3] (1908), who used a common Thoma-Zeiss hæmocytometer with a well 0 1 mm deep, an ordinary coverslip for microscopical work which, though specially chosen, is not optically plane, a 1 12th oil immersion lens, and a staining solution of weak Giemsa Owing to certain defects in these methods Glynn and Cox[4] in January, 1911, advised using the Helber chamber 0 02 mm deep with a special optically plane rigid coverslip 0 18 mm thick, and a diluting fluid of weak carbol thionin The Helber chamber was originally designed for the enumeration of blood plates, it and the cover slips are made by Zeiss Obviously as every laboratory worker possesses a Thoma-Zeiss hæmocytometer it is more economical to use this same apparatus for standardising vaccines But for reasons to be subsequently stated the Thoma-Zeiss chamber, which is 0 1 mm deep, is less suitable than the Helber chamber, which is only 0 02 mm deep Both these pieces of apparatus, however, give more accurate results than Wright's method of mixing measured volumes of bacterial emulsion and normal blood When standardising bacteria with a hæmocytometer chamber it is essential in order to diminish eye strain and increase accuracy first to stain the bacteria, and second to count them with an oil immersion lens The ordinary coverslips supplied with a Thoma-Zeiss chamber are too thick to permit the use of an oil immersion lens, and it has been necessary to devise a new coverslip suitable for use with most oil immersion lenses

Three points, therefore, have been considered (1) The most suitable staining fluid for diluting the bacterial emulsion in a hæmocytometer pipette, (2) the most suitable optically plane rigid coverslip for use with the Thoma Zeiss hæmocytometer chamber 0 1 mm deep and an oil immersion lens, and (3) the most suitable form of Helber chamber 0 02 mm deep and optically plane rigid coverslip for use with an oil immersion lens

Staining of the bacterial emulsion—After trying various methods we recommend a diluting fluid for the hæmocytometer pipettes of weak carbol thionin prepared as follows—Stock Solution A saturated thionin blue (Grubler) in absolute alcohol Stock Solution B 1 per cent of pure carbolic acid in clear tap water Before use take 1 part of Solution A to about 40 of B for most organisms, or 1 part of A to about 20 of B for streptococci The mixture will keep a considerable time, but should always be filtered before use, frequent filtration, however, may weaken the stain unless the filter paper is saturated with thionin It is important to keep the bacterial emulsions, stock solutions, counting chamber, and pipettes absolutely free from dust, particles of cotton wool, &c The most satisfactory method of preparing an absolutely dust free carbolic acid solution is to allow a large quantity to stand for a few days in a glass measuring cylinder, when the dust sinks to the bottom or rises to the top The capacity with which bacteria take up the carbol thionin stain varies somewhat with the type and sometimes the strain of the organism, or with the age of the culture Streptococci require stronger stain than most bacteria. If the proportion of thionin is too high the bacteria are stained almost instantaneously, and an abnormal number adhere to the under surface of the coverslip, agglutination also occurs

Agglutination is always present if too much thionin is employed. We have found by actual experiment that it does not depend upon the small quantity of alcohol or carbolic acid present in the solution, but upon the intensity of the staining Agglutination will also occur if the diluting pipette has been washed out with absolute alcohol and is not properly dried before use We are convinced that carbol thionin is superior to any other stain as methylene blue, fuchsin, or even the fashionable Giemsa It stains more intensely and is quite free from precipitate, further, the proportion of thionin can easily be adjusted to the staining capacity of the organism The great defect of the Giemsa solution is the tendency of the stain to precipitate even after filtration if the amount of Giemsa is strong enough to more than faintly colour the bacteria. We have been unable to remove the precipitate by substituting prolonged centrifugalisation for filtration

Brownian movement may be troublesome This, as can easily be demonstrated, is always more marked with *strong* emulsions, or when the bacteria are faintly stained, it ceases completely when the stain is strong enough to cause some agglutination, but agglutination is undesirable Brownian movement can be avoided in properly stained emulsions by not having more than an average of about half a dozen bacteria per square, a much larger number, even if motionless, is difficult to count The movement is more troublesome in counting chambers 0 1 mm than 0 02 mm deep

Bacteria adhering to the under surface of the coverslip—A certain proportion of the bacteria always adhere to the under surface of the cover slip and the number is increased by overstaining. In a series of over 100 observations made by the different observers it was found that the average number of staphylococci and colon bacilli adhering to the under surface of the coverslip was about 15 per cent. One point must be alluded to in the enumerating of bacilli like typhoid or colon—viz, they not infrequently stand at right angles to the coverslip or floor of the chamber, and consequently appear as round blue dots.

chamber or in the correct adjustment of the cover-slip is more serious

Settling of the bacteria in the counting chamber —One slight disadvantage of the chamber method is the difficulty of counting the bacteria when first introduced owing to their movement After a few minutes, however, the great majority settle at the bottom of the chamber and remain motionless, though some may continue in Brownian movement indefinitely Obviously the settling will take longer in a 0 1 mm than in a 0 02 mm chamber A large number of observations made upon the different strains of colon bacillus and staphylococcus indicated that whereas in a 0 02 mm. chamber the great majority of the bacteria had settled in 15 minutes, in a 0 1 mm. chamber a considerable number were still moving after half an hour A further series of observations showed that quite accurate accounts could be made with a 0 1 mm. chamber after the contents had settled for 15 minutes, provided that great care is taken to hunt for floating organisms Hunting for the floating bacteria takes a considerable time if many are present, far longer than in a 0 02 mm chamber Another advantage of the 0 02 mm. chamber is the greater facility with which the bacteria adhering to the under surface of the coverslip may be counted First, because only a slight turn of the fine adjustment is necessary to focus them, and second, because the outlines of the squares are still seen when the bacteria are focussed, and consequently there is no difficulty in ascertaining to which squares they belong

Summary of the advantages of the 0 02 mm chamber —Obviously it is more economical to standardise vaccines in the ordinary hæmocytometer counting chamber 0 1 mm. deep, but the 0 02 mm. chamber is preferable for the following reasons (1) The apparatus is suitable for all achromatic oil immersion lenses, even if the free working distance is as low as 0 09, (2) the cover slip being 0 18 mm thick is more durable, (3) almost all the bacteria settle at the bottom of the chamber in 15 minutes when accurate counts can be made, whereas in the 0 1 chamber a considerable number are still moving after half an hour, (4) bacteria adhering to the under surface of the cover slip and any still floating in the chamber are much more easily enumerated, (5) the optical definition of the bacteria is better owing to the smaller quantity of fluid, and (6) the difficulty of accurately adjusting the drop of emulsion in such a shallow chamber has been entirely removed by widening the safety trench for holding surplus fluid to 2 5 mm

The relative accuracy of the Wright and counting chamber methods for standardising vaccines —It is now 12 years since Wright[1] introduced his simple and ingenious method of standardising vaccines Though the method has been of great service to vaccine therapy we are convinced it suffers from two serious defects, first, it is usually very inaccurate, and second, it usually seriously underestimates the strength of the bacterial emulsion In order to ascertain whether the Wright or the chamber method gives the more accurate results, two observers independently standardised bacterial emulsions by each method, and the *percentage deviation from the arithmetic mean* of their counts was taken as a measure of the error in the method This is a more practical test of the accuracy than that obtained by two observers enumerating the bacteria in the same series of squares or microscopical fields Forty-four bacterial emulsions made from different strains of colon bacillus, staphylococcus and streptococcus were tested in duplicate in this manner We found that the average error was less than 5 per cent, with a minimum of 0 5 per cent and a maximum of 21 per cent for the chamber method, and more than 15 per cent, with a minimum of 1 1 per cent and a maximum of 54 per cent for Wright's

The error with a 0 1 mm chamber, though a little more than with a 0 02 mm., is also much less than in Wright's method In six bacterial emulsions of colon bacillus and staphylococcus standardised in a 0 02 mm and 0 1 mm. chambers and by Wright's method the average error was 3 1 per cent, 5 4 per cent, and 34 1 per cent respectively The average time occupied in counting these emulsions in the 0 02 mm chamber (64 squares) was 8 minutes, in the 0 1 mm chamber (64 squares) 10 minutes, with Wright's method (50 fields) 12½ minutes This further demonstrates the superiority of the hæmocytometer method, especially the 0 02 mm chamber

Wright's method usually underestimates the strength of the bacterial emulsions —This serious defect has been attributed to various causes In our opinion the chief are, first, a large number of isolated bacteria are usually left behind at the beginning of the smear, as we have shown elsewhere, second, small groups of bacteria mixed with blood platelets and leucocytes are drawn to the end of the film, where they are usually unnoticed unless specially looked for with a low power In both cases these bacteria almost certainly escape enumeration. It is no use trying to remedy this defect of unequal distribution of the bacteria and red cells by counting indiscriminately fields selected from all parts of the smear

A series of emulsions were standardised by the 0 02 mm chamber and Wright's method We found that the average percentage increase in 15 staphylococcus emulsions standardised by the 0 02 mm chamber over Wright's method was 76 per cent, with a maximum of 192 per cent, and in 12 emulsions of colon bacillus the average increase was 72 per cent, with a maximum of 228 per cent Additional figures are given elsewhere Rarely the chamber method gave a lower count than Wright's This is only to be expected on account of the unequal distribution of bacteria and red cells

Summary and Conclusions

1 The most scientific method of enumerating the bacteria for vaccines is in some form of hæmocytometer chamber

2 An optically plane and rigid coverslip must be used with such apparatus, for it is recognised as essential when counting blood and is still more essential when counting bacteria, where accuracy is of greater importance Owing to the small free working distance of oil immersion lenses most optically plane coverslips are too thick

3 Two types of hæmocytometer chamber may be employed (*a*) The ordinary chamber 0 1 mm deep, with an optically plane coverslip 0 13 mm thick. This is suitable for all oil immersion lenses with a free working distance of 0 17 mm and some of 0 15 mm (*b*) A chamber 0 02 mm deep, with a special safety trench 2 5 mm. wide and optically plane coverslip 0 18 mm. thick This is suitable for all achromatic oil immersion lenses, even if the free working distance is as low as 0 09

4 The 0 02 mm chamber is much superior for the following reasons (*a*) Almost all the bacteria

---

[1] Wright The Lancet July 5th 1902, p 11.

working distance of a lens partly depends upon the refractive index of the medium—air, water, or oil—between its under surface and the object examined. The greater the refractive index, the greater its free working distance Thus, the free working distance of a 1/12th Zeiss oil immersion lens is much *less* than 0 15 mm if no oil is used, as the refractive index of oil is 1 515 but that of air only 1

Professor Wilberforce kindly ascertained that the refractive index of the watery carbol thionin solution we employ was exactly the same as that of water, and may be taken as 1 333, the refractive index of the immersion oil supplied by Zeiss is 1 515 The substitution of 0 1 mm of water for 0 1 mm of oil will diminish the free working distance of the oil immersion lens according to the fraction $\frac{0\ 1 \times 1\ 515}{1\ 333} = 0\ 1136$—i e, 0 1 mm. of carbol thionin *is equivalent to* 0 114 *mm of immersion oil*—and the lens must be brought 0 014 mm. nearer the object than it otherwise would have been if the chamber contained oil instead of water (Fig 2) After a large number of experiments we have found that cemented coverslips of 0 18 mm and 0 15 mm are too thick for a 0 1 mm well, while those of 0 10 mm are liable to warp after much use Warping of the coverslips can easily be demonstrated by observing the images of the window frame reflected from its surface, when it will be noted that the lines of the frame are no longer straight

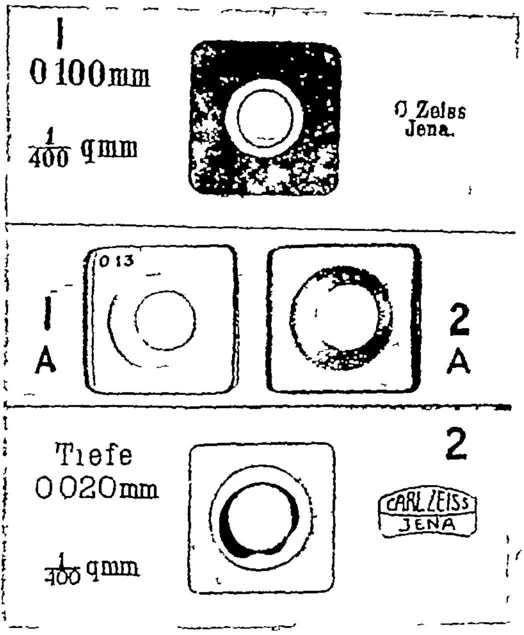
We have found, however, that a coverslip 0 13 mm thick is not only durable but also suitable for all achromatic oil immersion lenses *stated* to have a free working distance of 0 17 mm. and for those by most makers stated to have a free working distance of 0 15 mm The lens already alluded to with a reputed free working distance of 0 15 mm, but when *actually tested of only 0 08 mm.*, could not be used with a 0 1 mm chamber without *causing movement of the bacteria floating in the* fluid As the lens mount could not touch the coverslip, being 0 006 *mm* distant, the movement of the coverslip is explained by the immersion oil causing adhesion between it and the lens mount In order to make full allowance for the over estimation of the free working distance by some makers we have illustrated diagrammatically in Fig 2 a lens with a free working distance of 0 1 mm used with a hæmocytometer chamber 0 1 mm deep This lens has a corrected free working distance of 0 026, which is ample for ordinary purposes

Messrs Zeiss make such a coverslip, price 3*s*, which can be sterilised in formol or corrosive sublimate solution, but not with alcohol or xylol, for these substances dissolve the *cement* and cause warping We have found these coverslips still optically plane after several *months'* use, they are easily repaired if the cement is damaged.[7]

Standardisation with a hæmocytometer chamber 0 02 mm deep—The easiest and best method of eliminating the defect of the small free working distance of an oil immersion lens is to diminish the depth of the counting chamber instead of diminishing the thickness of the coverslip After experimenting with specially made counting chambers of various depths we have come to the conclusion that a 0 02 mm chamber with an optically plane cemented coverslip 0 18 mm thick as catalogued by Zeiss is the best, and suitable for all practical purposes This apparatus can be used with all achromatic oil immersion lenses, even with one by Watson N A 1 30, having a free working distance of 0 09 mm

Fig 3 shows that a lens with a free working distance of 0 1 mm used with such a counting chamber and coverslip has the corrected free working distance of 0 068 mm, which is ample The only disadvantage of the 0 02 counting chamber was the difficulty of spreading the drop, especially if the glass is slightly greasy We have completely remedied this defect by increasing the width of the trench from the usual 0 15 mm to 2 5 mm., for this provided a larger cistern for the overflow of surplus when the drop is a little too big (See Fig 4) If, however, the surplus of fluid is so great that it comes in contact with the opposite wall of the trench, then, as is well known, it spreads by capillary attraction everywhere under the coverslip, Newton's rings disappear, and *the depth of the* chamber is increased[8]

FIG 4



1 and 1A.—Ordinary 1 mm hæmocytometer chamber with new 0 13 coverslip suitable for all immersion lenses with a F W D of 0·17 mm and some of 0 15 mm 2 and 2A — New 0·02 mm chamber with wide safety trench and cover slip 0 18 mm thick suitable for all immersion lenses with a F W D *from* 0 17 mm *to* 0·09 mm. (*Note*—Too large a drop of methylene blue has been placed in 0·02 chamber and the excess is bulging *over* into the trench but owing to its extra width the fluid has not touched the opposite wall and so run under the coverslip by capillary attraction and increase the depth of chamber)

Calculation with a 0 02 mm chamber, the number of bacteria per square is multiplied by 20,000 instead of 4000 Bodley Scott[9] has recently recommended a counting chamber 0 01 mm deep and an optically plane coverslip, though he does not state how such a coverslip is obtained The disadvantage of such a counting chamber ten times shallower than the ordinary Thoma-Zeiss and twice as shallow as the Helber are two (1) The greater the difficulty in spreading the drop accurately, and (2) any error in the depth of the hour and the reading is taken, doubtful tubes being centrifugalised.

---

[7] Zeiss now make a 3 5 mm achromatic oil immersion lens with a free working distance large enough to take a 0·1 mm chamber with a coverslip 0·18 mm thick.

[8] This apparatus will be catalogued by Zeiss under the name of the Helber-Glynn chamber, price 15*s*

[9] *Scott T Bodley and Scott* G Bodley: THE LANCET Sept 28th 1912, p 879

Before determining the anticomplementary power of a substance it is important that the re-agents used be accurately standardised. The usual method of estimating the anticomplementary power of a substance by exposing it to two units of complement we consider to be very inaccurate, for before any interference with hæmolysis can be observed one whole unit of complement will have to be absorbed. Thus small but, as we have shown, important anticomplementary phenomena are continually not observed by workers who use the usual method.

3. *Antigenic factor.*—To each of a series of 10 tubes containing 1 c.c. of normal saline, 2 units of complement and 100 c.mm. of inactivated syphilitic serum are added, then graduated quantities of the antigenic emulsion, thus: 100, 80, 60, 40, 20 c.mm., and 100, 80, 60, 40, 20 c.mm. of 1 in 10. The tubes after mixing are placed in the water-bath at 38° C. for one hour, and at the end of this time 2 units of amboceptor and 100 c.mm. of 10 per cent. red cells are added and the tubes incubated for a further half hour. Readings are then taken, doubtful tubes being centrifugalised. The value of the antigen is expressed in the least quantity of the antigenic emulsion which will completely inhibit the hæmolytic action of 2 units of complement.

Standardisation of Amboceptor and Complement.

Amboceptor, antisheep[2] or antihuman, may be obtained in the usual way from rabbits; a convenient stock dilution may be kept in the ice-chest for three months. Complement may be obtained by decapitation of a guinea-pig (not pregnant), the blood being collected in a Petri dish to clot and separate for 24 hours in the ice-chest. (No vivisection licence is required for humanely killing an animal.)

The serum obtained in this way will have a constant titre provided that the animal has been kept in a cage with an excess of oats and green food always present. The clear serum is diluted half and half with normal saline.

The red cells, either sheep or human, are washed three times in the centrifuge with 0·9 per cent. saline. On the last washing the centrifugalisation is continued until the volume of the deposited red cells is constant. A 10 per cent. emulsion of corpuscles is made by adding 1 c.c. of this deposit to 9 c.c. of saline. Before proceeding with the actual Wassermann reaction an estimation of the amboceptor and complement should *always* be performed. The usual method is to estimate each separately. This wastes much time. If the approximate titre of each is known a simultaneous estimation of the two may be made. (Table I.)

Table I.—*Simultaneous Estimation of Amboceptor and Complement.*

Approximate titre of amboceptor, 70 c.mm.—30 c.mm. of 1 in 1000.
Approximate titre of complement, 50 c.mm.—30 c.mm. of 50 per cent.
Series of 12 tubes containing 1 c.c. of normal saline.

Tube No.	Amboceptor (1 in 1000).	Complement 50%.	Red cell suspension 10%.	Result after ½ hour in water-bath at 38° C.
1	70 c.mm.	50 c.mm.	100 c.mm.	Complete hæmolysis.
2	„	40 „	„	„ „
3	„	30 „	„	„ „
4	„	20 „	„	Marked hæmolysis.
5	50 c.mm.	50	„	Complete hæmolysis.
6	„	40 „	„	„ „
7	„	30 „	„	Marked hæmolysis.
8	„	20 „	„	Slight hæmolysis.
9	30 c.mm.	50 „	„	Very marked hæmolysis.
10	„	40 „	„	Slight hæmolysis.
11	„	30 „	„	„ „
12	„	20 „	„	„ „

In the above table the unit of each is contained in tube 6.

Table II. gives a scheme for the Wassermann reaction in which every factor is absolutely controlled. Further, we would draw attention to the increased delicacy of the reaction by using large quantities of the serum, 500 c.mm. (cerebro-spinal fluid 1000 c.mm.). These large quantities can only be employed with accuracy when a non-anticomplementary antigen is used since the serum is nearly always anticomplementary in these quantities.

Table II.—*A Wassermann Reaction.*

Test (front row).					Control (back row).				
Tube No.	Normal saline.	Antigen emulsion 1 in 10.	Complement units.	Serum inactivated 55° C. ½ hour.	Tube No.	Normal saline.	Antigen.	Complement units.	Serum inactivated.
	c.c.	c.mm.		c.mm.		c.c.			c.mm.
1	1	100	1½	100 A*	1	1	*Nil.*	1½	100 A*
2	1	100	1½	500 A*	2	1	*Nil.*	1½	500 A*
3	1	100	1½	100 B*	3	1	*Nil.*	1½	100 B*
4	1	100	1½	500 B*	4	1	*Nil.*	1½	500 B*
And so on for other sera.									
Further Controls.									
10	1	100	1½	*Nil*	10	1	*Nil.*	1½	*Nil.*
11	1	100	1½	100 normal.	11	1	*Nil.*	1½	100 normal.
12	1	100	1½	100 syphilitic.	12	1	*Nil.*	1½	100 syphilitic.

* A, B, &c., sera to be tested.

Mixed, incubated 1 hour at 38° C. in water-bath. Then 2 units of amboceptor and 100 c.mm. of 10 per cent. red cell suspension added to each tube. Re-mix, return to water-bath for half an hour, read.

In using large quantities of serum (0·5 c.c.) it might be urged that: (1) such quantities would alone interfere with complement and so render a reading impossible or dubious; (2) zone phenomena might arise—that is to say, that with larger quantities a less powerful fixation would occur; and (3) since it is said that between normal and syphilitic sera there is no qualitative difference, but only a quantitative one with regard to the Wassermann reaction, fixation might possibly occur with large quantities of normal serum.

Now dealing with (1), there is no possibility of error arising from this source in perfectly controlled systems, using a non-anticomplementary antigen. Here with an anticomplementary serum the same degree of inhibition of hæmolysis occurs in the test and control tubes, whereas if the serum is also syphilitic the test tube shows more inhibition than the control, thus rendering the reading obvious and free from fallacy.

(2) Browning and McKenzie demonstrate that with their antigen larger quantities of serum may fix less complement than smaller ones. Using our antigen, however, we have never been able to obtain this result, but have always got more fixation with the larger quantities of serum than with the smaller. Though we have carefully experimentally endeavoured to provoke zone phenomena

---

[2] Sheep hæmolytic serum may also be obtained from Messrs. Meister Lucius and Bruning.

in this way we have never been able to obtain them.

(3) Using even still larger quantities (1 c.c.) of normal sera and our purified antigen, we have never been able to demonstrate any true fixation. Thus, using a carefully controlled system, with a non-anticomplementary antigen, these large quantities of serum may be used with advantage without fear of error, especially as a smaller quantity—viz., 100 c.mm.—is simultaneously tested.

Any organ can be used for the purpose of extracting a good antigen, provided that the degree of autolysis which the organ has been allowed to undergo is the suitable one for that organ. It has been stated that the antigenic value of a phosphatid depends upon the tissue from which the phosphatid has been extracted. The observation that one organ has been found to give a better antigen than another is of no value, if the question of the degree of autolysis has not been considered. It must be remembered that different organs autolyse at different rates. Autolysis not only increases the antigenic value of the extract, but also the hæmolytic and anticomplementary properties. This fact has prevented other observers from obtaining a suitable antigen by this process; we have shown that purification of the phosphatid removes these complicating hæmolytic and anticomplementary factors.

The increased antigenic value of a phosphatid, extracted from a suitably autolysed tissue, is not due to the phosphatid forming an additive combination with cholesterin.

1. It is perfectly true that autolysis increases the amount of cholesterin, but this increase in the short time during which the tissue has been allowed to undergo autolysis (24–36 hours) at the room temperature is very slight.

2. We have experimentally demonstrated that our purified phosphatid does not contain cholesterin.

3. And that a phosphatid extracted from a fresh organ in the presence of a saturated alcoholic suspension of cholesterin does not possess antigenic properties.(*1)

With regard to extracts from congenital syphilitic organs, we have found that the antigenic value has no connexion with the spirochæte content, but depends upon the degree of autolysis of the organ.(*2) The antigenic properties of extracts of these organs are in no way superior to extracts from autolysed normal organs. These antigens are suitable for use, providing that their marked hæmolytic and anticomplementary properties are removed by purification.

All experiments relating to "the remarkable action of cholesterin in increasing the action of lecithin as *antigen*" (*3) are open to the criticism that an accurate quantitative analysis has never been performed. We have constructed an experiment (*4) exactly reproducing experiments of Browning and McKenzie (*5), and have shown that cholesterin produces identically the same effect whether added to a syphilitic serum and antigen mixture or to a non-syphilitic serum, which by itself would cause the same amount of complement inhibition as the syphilitic serum with lecithin antigen alone. That is to say, that the action of cholesterin is not specific to syphilis, but enhances anticomplementary properties whether pre-existing or brought about by a syphilitic serum and antigen mixture, and thus cholesterin may occasionally cause a normal serum to be diagnosed as positive. Thus our statement that "the use of cholesterin ...... is not only unnecessary but introduces a serious source of error" (*2) is not based on theoretical considerations, but on experimental work where the subject has been fully considered (*1).

Finally, "certain methods are admitted to yield too high a percentage of positives, and these to any logical mind must be completely disregarded so far as their employment for diagnostic purposes is concerned; it is obvious that any form of the test which is liable to return positive reactions in cases which are not syphilitic is useless for diagnosis, however valuable such a method may be as an indication for the continuance of treatment in known cases of syphilis" (*3). There has recently appeared an article (*6) by McIlroy and Watson, who examined by the method of Browning, Cruickshank, and McKenzie 100 cases of women mainly from the obstetrical out-patient department "not selected from the point of view of the Wassermann test."

The cases were from the respectable working-class; obvious cases of syphilis were not included. They found—

Positive to the reaction	43
Doubtful...	9
Negative...	48

Of these 48 negatives, 7 had children which gave a positive, thus making more than half of the population of the respectable working-class syphilitic. That these results are suspiciously high must be self-evident, and they make an impartial observer suspicious of a method that gives so many positive results.

In conclusion, the method of performing the Wassermann reaction that we bring forward in this paper is exceedingly simple, quick, and absolutely controlled. It will be noticed that no vivisection licence is required, a matter of considerable importance in many laboratories. The antigen has been used now in several thousands of cases and has consistently given excellent results.

NOTES ON DIABETIC RETINITIS.

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THERE is much difference of opinion on the subject of diabetic retinitis. Some maintain that there is no such a thing; others that the retinitis which occurs is albuminuric and due to the association of diabetes with granular kidney; while others hold that there is a form which is perfectly characteristic and pathognomonic.

I have seen many cases of retinitis in diabetes, and I may say at once that I have failed to observe anything whatever characteristic in it—that is to say, nothing by which from the change in the retina diabetes could be diagnosed as granular kidney can. I have had cases shown me more than once which were said to be typical, but they did not convince me, and so far as my own experience goes I should say that it was impossible to diagnose diabetes from anything that can be seen in the retina.

I agree, too, with the statement that many cases of so-called diabetic retinitis are typically albuminuric, and are due to the association of diabetes with granular kidney, an association which is by no means rare. But this does not exhaust the subject.

There are two forms of albuminuric retinitis, which I have called the degenerative and the exsudative respectively.

The degenerative form is the familiar and well-recognised type characterised by the white glistening patches of degeneration of varying sizes, and grouped especially round about the yellow spot, but whether large or small equally characteristic and quite pathognomonic, for they occur with no other disease.

In the exsudative form there is exsudation involving the disc and extending from the disc outwards in any direction; the patches of exsudation may be of larger or smaller size, but if small never present the bright glistening appearance characteristic of the other form, but are of a dull yellowish colour, and a woolly or fluffy character, with no sharply defined margins. There is nothing in this form to distinguish it from the neuro-retinitis of other affections—e.g., that which occurs with cerebral tumour. This form may occur in acute nephritis as well as chronic. It may disappear entirely as the nephritis recovers, while the degenerative patches are persistent and practically never disappear, probably because the renal lesions are permanent.

The exsudative form is in all cases, I believe, of toxic origin, and might therefore arise in the course of diabetes, just as it does in the course of acute nephritis, and this, in my opinion, is the fact, for I have certainly seen cases of this kind in which there was no evidence of granular kidney.

The view I am expressing would reconcile and explain the different opinions held. The degenerative form would be characteristic of granular kidney, whether associated with diabetes or not. The exsudative form would be of toxic origin and indistinguishable from that which is seen in other toxic states, and be due to some poison produced in diabetes which attacks the optic nerve and retina just as it sometimes does the peripheral nerves. What the poison is we know no more in diabetes than we do in nephritis.

Wimpole-street, W.

THE THERAPEUTIC VALUE OF THE POTATO.

BY HEATON C. HOWARD, L.R.C.P. LOND., M.R.C.S. ENG.

IN considering generally the results of the treatment I am about to describe, there are two facts which stand out most prominently, and which emphasise in a marked degree the peculiar properties of the raw potato juice. The first is the prompt relief from pain, acute or subacute, which is shown to have occurred, and the second is the rapid absorption of the fluid in cases of synovitis. These results, so unexpected when the investigation was commenced, have been so constant and so thoroughly tested in the many cases under my care that I now feel justified in bringing them before the medical profession hoping that the treatment, if carried out as recommended, will meet with similar success at the hands of other practitioners.

My investigations of the therapeutic uses of the potato, though carried on for some years, are not yet completed. The initial difficulty of ascertaining the kind of complaint the potato would relieve and of deciding upon the part of the plant to be used and then of the method of making the preparation will be appreciated.

Preparations.—It seems on investigation of the juice of the potato that there is no alkaloid in it and that the chief ingredient is potash salts, which are present in large quantity. The basis of all the preparations is the liquid extract; "extractum solani liquidum" is the name given to it. It is made as follows:—The raw potatoes are put into a hydraulic press and the liquid is squeezed out. About half the weight of the potato comes away as juice. The starch and the nitrogenous matter are removed, leaving the juice with the salts only in it. It is then concentrated down by heat and some glycerine added in order to preserve it, until it is made five times the strength of the juice, therefore ten times the strength of the potato itself. The ointment is made the same strength as the extract, and is prepared chiefly with lard. A liniment is made by taking equal parts of the extract and lin. saponis co., or 2 of extract and 1 of soap liniment. The plaster is made as ordinary plaster and is of the strength 10 to 1. The ampullæ contain the pure extract, which is five times the strength of the juice and properly sterilised. I have as yet not had much experience in the hypodermic use of the remedy. All these preparations are made by Messrs. Baiss Brothers and Stevenson, of Grange-road, Bermondsey, and are sold at a moderate price.

Pain.—In the following notes for purposes of description pain is divided into two large sections, active and passive, thus:—

PAIN.

Active.	*Passive.*
Severe.	Severe.
Moderate.	Moderate.
Slight.	Slight.

Active pain is felt when the body is quite still, as in acute gout of the toe, neuralgia, pain after injury, headache, &c., and the exact character can be further described by prefixing adjectives such as tearing, gnawing, stabbing, shooting, &c.

Passive pain is that felt on movement of a part or limb, as in rheumatism and gouty joints after the active pain has gone, also in subacute rheumatism, fibrositis, &c. Other further descriptive adjectives can be added.

Synovitis.

The action of the liquid extract on acute synovitis (with effusion) of the knee-joint, whether traumatic or gouty, is speedily to relieve the pain, which does not recur, and to cause absorption of the fluid in four, five, or six days. After the fluid has disappeared the slightly thickened synovial membrane can usually be felt for a day or two. One or two days' application of the ointment will remove it. At the end of a week the patient can get up, using the knee as little as possible. The knee should have a flannel bandage put on, and in about 14 or 16 days from commencement of treatment the patient will be able to resume his work. If he gets about too soon the fluid is liable to return. This mode of treatment is simple, speedy in its result, and appears trustworthy in its action.

the origin of this particular growth seems only explicable on the "cell-rest" theory of Cohnheim. The patient's wife told me that he had had a cough all his life. The discharge from the sinus in the antrum merely aggravated the symptoms, and cannot be considered to have any bearings on the etiology. I sent one of the enlarged cervical glands to Dr. Eastes's laboratory, where a very beautiful section was made revealing the features of a typical, rather large round-celled sarcoma. Sir William Osler states that the usual duration of primary lung sarcoma is from six to eights months and that sarcoma is rarer than carcinoma. This particular case appears to be unique in its slowness of development

Briton Ferry, Glam.

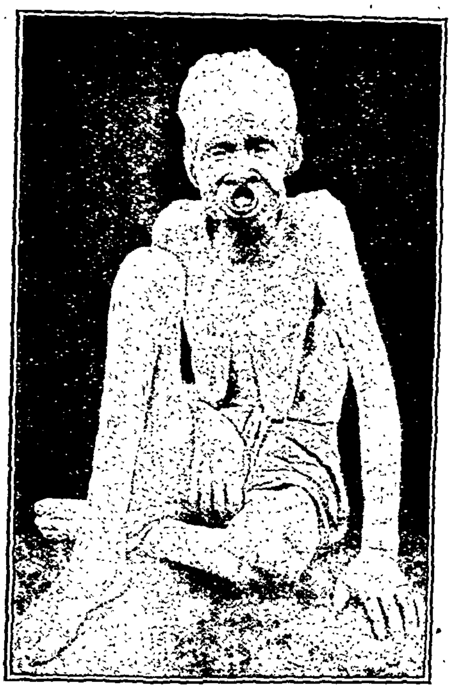
THE LIFE-SPAN OF NEGROES.

By HUGH S. STANNUS, M.D. LOND., D.T.M. & H. CANTAB.,
MEDICAL OFFICER, NYASALAND ADMINISTRATION.

IN an annotation in THE LANCET of Nov. 29th, 1913, under the heading "Mortality Among African Negroes," there are some references to observations made by Dr. R. Mouchet in the Congo published in the *Archiv für Schiffs- und Tropen-Hygiene*. Your annotator asks the question: "At what age does a negro in tropical Africa die?" and appears content to accept Dr. Mouchet's observations as the answer to that question. I, unfortunately, have not got the original article to refer to here, but as a medical man with some nine years' experience of another part of tropical Africa, I write to put down a few observations of my own on natives of Nyasaland, in order to prevent readers of your annotation going away with the idea that all the conditions mentioned in the above article are true for the whole of tropical Africa. Dr. Mouchet is of opinion that natives die far younger than Europeans. He says a grey-haired native is rare; "cataract, tumours, atheroma, and kidney disease are hardly ever found."

In Nyasaland (the natives are all of Bantu stock) white-haired natives are to be commonly seen in any village, and search among them reveals quite a fair proportion of cases of senile cataract. It is true that it is impossible in the absence of official birth registration to ascertain the exact ages of these individuals, but in some the approximate age can be deduced from relative facts and dates. A well-known Yao chief, Chemposa, whose age must be approximately 60–65, is a grey-haired man, but still quite active, and in his village there are many who appear older than he.

That natives may live to a very old age is, I think, borne out by the photograph of a white-haired old woman met with near Lake Amaramba, the subject of a double cataract, whose pulse had slowed down, owing to her not having moved for many years, to 40 per minute. Her son and daughter were grey-haired old people, and her grandson, a man of middle age, had a son who might have had children. May I suggest that Dr. Mouchet's observations were possibly limited to certain classes of natives, and that he had not in Léopoldville opportunities for seeing the old people who remain in their villages? The same thing, I think, probably accounts for his statistics as to the cause of death. In 37 out of 100 necropsies he found tuberculosis as the cause of death, but these figures cannot surely be true for the whole population of the country. Judging by this country, it is the over-civilised, over-clothed males of young adult age who travel and live in townships that are most likely to come to the post-mortem table, and it is exactly among this class of native that tuberculosis is seen. I agree with Dr. Mouchet that atheroma and kidney disease are comparatively rare among natives, but judging by my own clinical experience I am inclined to the opinion that malignant growths are not so uncommon as is generally supposed. That natives may die younger than Europeans may be true, but that none or few reach old age I look upon as one of the many myths about natives which have been believed in the past and are very difficult to eradicate.



Zomba, Nyasaland.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.—The annual general meeting of this society was held at 32, Craven-street, Strand, London, W.C., on March 25th. Mr. C. M. Fegen took the chair in the absence of Dr. G. A. Heron, the President. The chairman, in presenting the annual report, which was referred to in THE LANCET of March 21st (p. 842), pointed out that, with the passing of the National Insurance Act, the work of the society had increased, and would materially increase in the future. He referred with pleasure to the financial statement at the end of the report, which showed that the society was in an excellent position having regard to the number of members. The society had always been solvent, but its position was strengthened owing to the establishment of the insurance scheme. The members were asked to pay an addition to their usual subscription, and that addition had provided a great deal of protection which they did not have before from the society. Dr. W. Knowsley Sibley criticised the conduct of the council in the action against St. John's Hospital for Diseases of the Skin, and the chairman and the financial secretary replied, maintaining that his criticisms were founded on misconceptions as to the facts of the case. The report and balance-sheet were then adopted, and Dr. Heron was appointed president of the society for the ensuing year. The vice-presidents, the treasurer, the retiring members of council, the secretaries, and the auditors were re-elected, and the meeting terminated with a vote of thanks to the chairman.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Laryngeal Tuberculosis.—Tonsils and Adenoids in Children.

A MEETING of this society was held on March 30th, Sir **DAVID FERRIER**, the President, being in the chair.

Sir **STCLAIR THOMSON** read a paper on Three Years' Sanatorium Experience of Laryngeal Tuberculosis. He said that the outlook for patients suffering from tuberculosis of the larynx is less gloomy than it was 32 years ago, but that it is still a serious complication. The following conclusions were advanced: 1. The larynx is frequently involved in pulmonary tuberculosis. Even in the selected cases sent to a sanatorium it is met with in 25·6 per cent. 2. A considerable number of cases (102 out of 795) are sent to a sanatorium without their showing active tuberculosis. These cases, if included in statistics, would largely help to invalidate conclusions. 3. In patients of the middle class laryngeal tuberculosis is met with just as frequently in females (28·3 per cent.) as in males (24 per cent.). 4. Laryngeal tuberculosis occurs much more frequently (13·7) in the early favourable cases of phthisis than is generally recognised. 5. In the more decided cases this proportion is doubled (27·1 per cent.), and in the advanced cases it is trebled (40·8 per cent.). 6. The expectation of life amongst consumptives is markedly decreased by the complication of laryngeal tuberculosis. 7. As a factor in prognosis, the laryngeal condition deserves much more regard than it has hitherto obtained. 8. Laryngeal tuberculosis may not infrequently be present, although the patient makes no complaint of the throat and although the voice is unaltered. Hence—9. The larynx should be carefully inspected in every case of pulmonary tuberculosis. 10. Arrest of laryngeal tuberculosis can be effected in a sanatorium in 20·7 per cent. of all cases. 11. Improvement in the lung and the larynx frequently, but not invariably, progress *pari passu* in a sanatorium. 12. In certain cases the larynx improves while the lung retrogresses. The converse takes place rarely. 13. Limited and slight laryngeal lesions, particularly in mild and moderately severe cases of phthisis, may become arrested *spontaneously* with sanatorium treatment. 14. The galvano-cautery is the best weapon we have at present for local treatment. It was only indicated in 20·22 per cent. of all cases, and it completed the cure in 41·66 per cent. of the cases in which it was employed. 15. These satisfactory results have not, so far as the author knew, been secured by any methods outside a sanatorium. 16. Sanatorium treatment is at present the first and most valuable method we have for arresting laryngeal tuberculosis. 17. Local measures are much more promising under sanatorium conditions. 18. At present the diagnosis of tuberculosis is too long delayed, or the patient is sent to a sanatorium much too late to effect a cure. Hence—19. With our present methods of therapeutic resources we must, for progress, urge the importance of early diagnosis and then prompt sanatorium treatment.

Dr. **F. DE HAVILLAND HALL** said that in the past he had been pleased by the beneficent effects of lactic acid of gradually increasing strengths. No doubt the results would have been still better if sanatorium treatment had been employed as well.

Dr. **T. D. ACLAND** remarked that he was glad to hear Sir StClair Thomson's opinion of the effect of tuberculin. The author had said that he had not seen any benefit from it, but he (Dr. Acland) was quite certain that he had seen harm result.

Dr. **P. HORTON-SMITH HARTLEY** asked which cases were the most suitable for galvano-cautery, and what treatment was used for those with definite ulceration. He spoke of the difficulty which the physician experienced in detecting cases early enough for the most favourable prognosis without swelling the numbers of the patients at the sanatorium who could not be classed definitely as tuberculous.

Dr. **S. VERE PEARSON** was also anxious to have formulated the indications for the use of the galvano-cautery. He referred to the question of punching out or removing the epiglottis. He had seen cases where only the epiglottis was affected. Should the epiglottis be removed under those circumstances? In cases of doubtful diagnosis he thought that the patients should be given the benefit of the doubt, which to-day meant sending them to a sanatorium. He also spoke of the possibility of treatment by nascent iodine. By this method sodium iodide was given internally, and either the larynx sprayed with hydrogen peroxide or ozone inhaled. In this way nascent iodine was set free.

Dr. **N. D. BARDSWELL** said that at the King Edward VII. Sanatorium the cases were subjected to the following examination: first, the sputum was examined by all modern methods for bacilli; secondly, the complement-fixation test was employed; thirdly, the opsonic index was estimated both at rest and after exercise; and fourthly, if these tests were negative the subcutaneous tuberculin test was used. If the results of the last three procedures were negative the patient was probably not tuberculous. A choice had often to be made between the general clinical picture and the laboratory tests, and the whole question of diagnosis was still unsettled. Although at present the cases which could not be shown to be actively tuberculous were excluded from statistics to disarm criticism, it was probable that in the future some of them might be shown to be examples of latent tuberculosis. He would go farther than Sir StClair Thomson and say that the larynges of all patients suffering from pulmonary tuberculosis should be examined, not once, but periodically. With regard to local treatment, the galvano-cautery gave the best results, but was of very limited application. He had seen ill effects from its use. It might do harm if applied to active lesions when the general condition of the patient was unfavourable and the pulmonary disease was not quiescent.

Dr. **H. TILLEY**, speaking of active treatment, said that he never interfered with a laryngeal lesion if there were active signs in the chest, and the only lesion in the larynx suitable for local treatment was a limited one. The galvano-cautery was only applicable for a small percentage of cases. Rest was so essential that everything should be done to prevent coughing. Few methods gave more relief in this respect than the inhalation of vapours such as those containing creasote. He had seen good results with the use of nascent iodine in chronic lesions of the lupoid form. He had not used lactic acid for the last five years.

Dr. **G. WILLIAM HILL** pointed out that the paper dealt with statistics of a very limited group of cases—namely, those of patients who obtained admission to a sanatorium, and questioned whether the earlier statistics could be regarded as vitiated if this fact were taken into account. He spoke of the difficulties of determining the presence of active disease in the lung.

Mr. **E. B. WAGGETT** said he would be interested to hear a comparison between the results of private cases and those in sanatoriums. His experience was that tuberculomata were benefited by the galvano-cautery whilst the pseudo-œdematous form of laryngeal tuberculosis did badly.

Dr. **W. CAMAC WILKINSON** said that from a consideration of the statistics one must be impressed by the hopelessness of the treatment of laryngeal tuberculosis by ordinary methods. He had given up the use of lactic acid in 1897 because he found that tuberculin gave much better results than other methods. It was not necessary to take selected cases, but he had obtained good results with tuberculin, even in those which had been rejected. He was convinced that tuberculin, given in large doses and in no other way, would in future prove to furnish far better results than any other method, including the galvano-cautery. The results were infinitely better than those mentioned in the paper. The question was a difficult one, as all such statistics lacked relativity.

Mr. **H. W. CARSON** spoke of the value of rest and of continuous inhalation for reducing cough. There was a stage when the lung condition was quiescent but where no improvement continued in the laryngeal condition. In these cases the galvano-cautery did good service. He had found that only in those patients who could respond to tuberculin were good results obtained.

Sir **STCLAIR THOMSON**, in reply, said that there was very little call in sanatoriums for symptomatic treatment. One could be more certain of what one was doing with the galvano-cautery than with lactic acid. Its use was to start Nature's process of healing by fibrosis. It was indicated for localised indolent lesions, and where the general condition was favourable and the signs were not those of active tuberculosis. The presence of tubercle bacilli was not necessarily a contraindication.

Mr. T. B. Layton read a paper entitled "Tonsils and Adenoids in Children: a Plea for Fewer Operations," which will appear in full in a later issue.

HUNTERIAN SOCIETY.

The Causes and Treatment of High Blood Pressure.

A MEETING of this society was held on March 25th, Mr. W. J. M. Ettles, the President, being in the chair.

The annual discussion of the society was opened by Dr. F. de Havilland Hall, who read a paper on the above subject. He pointed out that blood pressure normally varied with the age and sex of the individual. A ready method of remembering the average blood pressure was to place 1 before the age of the person, and this would give in millimetres of mercury the pressure appropriate to the age in question, but over 40 the figures were too high. In women the pressure was usually 10 mm. below that of a man of corresponding age. A wide range of variation in pressure was met with in individuals. Dr. Hall quoted with approval the custom of certain American life insurance companies, who require a record of the systolic pressure whenever the age of the proposer is 45 years or over, and fix a limit of about 150 mm. at and over which no life is accepted on normal terms. The time of day and the condition of the nervous system, he said, influence blood pressure. A strong, healthy man has normally a blood pressure 5 to 15 mm. above that of a weakly individual. Active muscular exertion causes an increase of blood pressure, as does also the ingestion of a large amount of liquid, and especially beer. The onset of acute fever and severe pain are accompanied by increased blood pressure. Great stress was laid on the toxæmia of gastro-intestinal origin due to over-eating as a very important cause of increased blood pressure. The constant strain to which the arteries were thereby exposed led to arterio-sclerosis, and that which at first was only a temporary condition, the pre-sclerotic stage of Hachard, became a permanent state of high tension. Kidney disease was stated to be one of the most certain causes of increased blood pressure, and a repeated and constant pressure of over 200 mm. would suggest the presence of some form of nephritis. Gout, lead-poisoning, malaria, syphilis, and oral sepsis were mentioned as causes of increased blood pressure. Alcohol, either directly or by its effect on the gastro-intestinal tract, was a cause of high pressure; tea and coffee had also some action in raising the pressure. Tobacco caused an increase of pressure, but the habitual smoker had usually low pressure. Finally, mental strain and worry, especially if combined with deficient exercise and too rich living, were stated to be potent causes of high blood pressure. Before entering upon the question of treatment Dr. Hall insisted upon the importance of recognising that so far from high tension being the enemy which was to be met and overcome, it was often the patient's great ally, and was the means whereby the functional activity of the kidneys was maintained and life preserved. He laid stress upon the disastrous effects resulting from the injudicious employment of measures to reduce high pressure; and also upon the danger of a stimulating plan of treatment in arterio-sclerotics with high pressure. Among the measures capable of reducing high pressure rest, he said, takes a prominent position, and in patients with a pressure of 200 mm. and upwards, especially if combined with any signs of heart failure, a period of absolute rest should be enjoined. Many cases, however, of high pressure occur in people who take too little exercise, and for them suitable exercise, such as riding, cycling, walking, and golf, should be prescribed. The methods of Schott and Oertel were alluded to. Massage was recommended in cases in which sufficient exercise could not be taken. The condition of the skin required careful attention; warm baths or Turkish baths might be ordered in suitable cases. The electric light bath and the D'Arsonval current of high frequency often gave good results. If obesity were present the Bergonié system might be warmly recommended. In many cases the Nauheim treatment gave excellent results. Diet was all-important; the quantity as well as the quality of food required careful supervision. Substances rich in nitrogen, such as butcher's meat, should be avoided. Soured milk was useful in dyspeptic cases. Tea and coffee should be taken with great moderation. Alcohol was almost always prejudicial in cases of high pressure. An abundant supply of pure water, preferably distilled, to drink was indicated. Tobacco should be indulged in with the greatest moderation, and if there were anginal symptoms it should not be allowed. Drugs played a secondary part in treatment. Calomel, blue pill, and the saline aperients were most useful. Iodides given in small doses and for a considerable period of time had a very beneficial effect. In patients giving a positive Wassermann reaction mercury should be administered, preferably by inunction. Salvarsan was not recommended. In cases of high pressure at the menopause attended with obesity small doses of thyroid extract, together with a combination of bromide and iodide of potassium, would be found most useful. If the iodides were badly borne sodium nitrite in doses of 1 to 2 grains in chocolate tablets might be given. The hippurate of lithium in doses of 1 to 2 grains given twice daily would be found to have a good effect. The more powerful and more quickly acting vaso-dilators, such as amyl nitrite, nitroglycerine, and erythrol tetranitrate, should be reserved for emergencies—e.g., anginal or dyspnœal attacks—rather than for regular use. Blood-letting was a remedy which was of the greatest possible service in certain cases of high blood pressure. Nature itself seemed to indicate the appropriate remedy in many cases by the onset of copious epistaxis.

Dr. W. Langdon Brown called attention to the difficulty in getting a correct record of the blood pressure in nervous subjects, in whom the mere attempt to make the observation raised it temporarily, and also to the drop in the pressure which occurred as old age advanced. Men of over 80 usually had a pressure of about 140 mm. Other factors in producing high pressure were over-action of certain ductless glands, such as the pituitary and suprarenal, and the putrefactive diamines formed in the bowel, which had been shown to be definitely pressor in action. The great and abiding difficulty which beset treatment was that the pressure requisite for any given degree of arterio-sclerosis was not known. What was known was that the rise of pressure was a conservative measure and must not be antagonised without reference to the cause of the rise. But just as hyperpyrexia might have to be treated, whatever the cause of the fever, so hyperpiesis might have to be treated as an emergency. Then, and then only, was the time for nitrites. Amyl nitrite was best for immediate lowering of pressure, as in anginal attacks; nitroglycerine would only lower pressure for 40 minutes, while erythrol tetranitrate in ½-grain doses could do so for six hours. The chief drawback to its use was the severe headache it sometimes caused. Iodides did not lower pressure by vaso-dilatation, but by eliminating toxins, and were therefore not included in this condemnation. Sulphates acted not only as aperients, but by combining with putrefactive substances had an antitoxic action as well. The most important thing was to detect these cases in the presclerotic stage, before organic changes had occurred, and then to treat them by putting them in the way of physiological righteousness rather than by depressor drugs.

Dr. S. Russell Wells emphasised the importance of recording the diastolic as well as the systolic arterial pressure. In cases of aortic regurgitation, for instance, the systolic pressure as recorded by the Riva-Rocci instrument might be very high and the diastolic pressure very low, so that the continuous strain to which the arterial wall was exposed was not nearly so great as it was in cases of arterio-sclerosis with much lower systolic and higher diastolic pressures. He referred to some experiments which he had made with specially constructed rubber tubes, showing that these tubes could stand a very high systolic pressure, provided that the diastolic pressure was small, while a high diastolic with a comparatively low systolic produced aneurysmal dilatations. He then detailed some experiments and observations made by Professor Leonard Hill and himself which led them to suppose that the character of the blood stream at the threshold of any capillary area materially depended upon the state of the wall of the artery supplying that area. If the arteries going to a part had hard and more or less rigid walls the blood pressures would approach those in the aorta and show high systolic and low diastolic readings; while if the arteries were soft and distensible the blood stream would be broken down to something more approaching a continuous flow, the systolic pressure being much lower and the diastolic higher than in the previous case. Since all the arteries and to a greater extent the arterioles were contractile and under the influence of the nervous system and with an increased tone or contraction their walls became harder and less labile, it might well be that the organism could with the same heart-force vary the pressure at the threshold of any capillary area between an intermittent pressure with a high systolic beat and an almost continuous one with a lower systolic pressure. In the one case there would be a hammerlike percussive wave beating open the capillaries, and in the other a more continuous pressing in of the blood at a lower tension. It was suggested that the throbbing felt and the capillary pulse observed in an acutely inflamed area might be due to an increased tone of the walls of the afferent artery which lessened their resilience; hot fomentations relieved this throbbing by relaxing the contraction of the vessel walls. The observations of Leonard Hill and Martin Flack on blood and secretory pressures in secreting salivary glands were alluded to, and it was pointed out that under certain conditions a temporary rigidity of the arteries of the arm might give a raised systolic reading by causing the full systolic crest of the aortic pressure to be conducted down to the armlet without there really being any rise of the systolic pressure over the body generally. Dr. Langdon Brown uttered a word of caution against too lightly attempting to lower even a very high systolic pressure in cases of arteriosclerosis without regard to the patient's general condition, and instanced the case of a patient of his own who for the last four years had shown systolic readings, taken with the Riva-Rocci instrument, of 300 mm. of mercury, whose general condition became notably worse when these readings fell to 250, and improved again when they returned to their former level.

Dr. O. K. WILLIAMSON said that, as regards diagnosis by means of a sphygmomanometer, cases were met with in which, owing to arterial thickening associated with spasm at the site of compression, the instrument yielded a high reading when the actual blood pressure was certainly not above normal. For instance, a case of hemiplegia more or less sudden in onset might be met with in which such a condition of the arterial wall was present, and in which the instrument yielded a high reading but in which the blood pressure was actually low, and in which the symptoms were due to spasm of a branch of the middle cerebral artery. If in blind obedience to the instrument depressant treatment were adopted the condition might easily pass into one of cerebral thrombosis, whereas by using the finger as well as the sphygmomanometer such a grave error could be avoided and the correct treatment adopted—viz., the use of a vaso-dilator combined with a cardiac stimulant. Hence the vital importance of using the finger as well as the instrument in the examination of the pulse. In regard to treatment naturally cases in which the pressure was temporarily raised yielded better results than did those in which the condition was persistent, and in which the arterial changes were more widespread. It was often impossible to tell from one examination which of these two classes was being dealt with, for in a case in which there were extensive changes involving especially the splanchnic arteries the arteries accessible to superficial examination might not reveal obvious disease. In cases in which there was no special symptom which called for treatment, although he agreed with Dr. Hall and Dr. Langdon Brown that it was undesirable to make a routine practice of reducing the pressure, still it seemed to him advisable to try cautiously the effect of reducing the pressure, inasmuch as the continuance of the condition was, other things being equal, in itself harmful. Great caution was, however, necessary in such cases, and the effect of such treatment on the patient's general health and symptoms should be noted, as many of these patients would not bear reduction in their blood pressure. Treatment was also called for in cases in which high blood pressure was associated with marked local spasm of arteries and consequent interference with function in areas which these supplied; it then became, especially in the case of the heart or brain, an urgent matter. In regard to treatment by rest, whilst rest in bed was in many cases invaluable, he would add a word of caution against overdoing it. He had seen cases which had been treated by rest in bed for several weeks without showing any appreciable fall in pressure, but when the patients had been allowed to get up and walk about they had quickly experienced a fall. As regards drugs, it was of great importance to secure a regular free action of the bowels by means of saline aperients, and an occasional dose of calomel was of great value. He had obtained good results from small doses of iodide of potassium, and in cases in which this was ill borne, from iodipin, and especially from sajodin, the last-named being given in tablet form in doses of 7½ grains. Of the vaso-dilators he had found erythrol tetranitrate the most useful. He had found guipsine serviceable in some cases; it was given in pill form in 5-grm. doses, and in amounts varying from 6 to 25 pills in the 24 hours.

Dr. LIONEL C. E. CALTHROP (Woodhall Spa) said that many cases of high blood pressure were sent to Woodhall Spa for treatment owing to the fact that it was the only mineral water in Great Britain which contained potassium iodide, the value of which in this condition was now established. The water also contained a certain quantity of bromide of potassium, constituting a useful adjunct to the iodides in irritable states. The action of this water on the bowels and kidneys assisted its beneficial effect. He thought with Dr. de Havilland Hall that though in some cases Nauheim baths were suitable, yet in others the ordinary hot mineral baths or the electric light baths, which were more eliminative in character, afforded greater relief. Diet and drink were important factors, also rest and moderate exercise, such as golf. Owing to its special features he thought this spa admirably adapted for the treatment of these cases.

Dr. LESLIE C. THORNE THORNE said that his investigations of blood pressure in cases of cardiac disease, including a large number of patients undergoing the Nauheim treatment, had convinced him that the record of minimum blood pressure was almost as important as that of the maximum, as there existed two very distinct classes of cases in which hypertension was present, and these two classes could only be differentiated by a comparison of the ratios of the maximum and the minimum blood pressures. In the first class both the maximum and the minimum pressures were raised, but the ratio of the two pressures was altered, there being a greater difference between them than in a normal case. The normal difference between the maximum and the minimum pressures was about 50 mm. Hg, but in a case of this kind there might be a difference of over 100 mm. Hg between the two readings; for example, the minimum pressure might be 120 mm. Hg and the maximum 250 mm. Hg. A difference in ratio of this kind, he believed, indicated definite vessel degeneration. In the second class, both the maximum and the minimum pressures were raised, but the ratio between the two was unaltered; for example, the maximum pressure might be 150 mm. Hg and the minimum 100 mm. Hg. He was of opinion that readings of this kind indicated a raised pressure due solely to hypercontractility of the arteries and capillaries—a presclerotic condition. In the first class, suitable treatment might lower the pressure to a certain extent, and would undoubtedly relieve dangerous symptoms, but the decrease in pressure would not be maintained, and if drugs were pressed to try to maintain it the patient would be rendered worse rather than better. In the second class, suitable treatment—notably, Nauheim baths and dietary—would, by improving nutrition and increasing metabolism, bring the pressure down to normal, and this condition might, with care, be maintained for years. He was convinced that many of the symptoms accompanying hypertension were due to cardiac failure and consequent dilatation, and he found that if this dilatation was treated and cured dangerous and painful symptoms were relieved. He had treated a number of cases of hypertension due to chronic nephritis with Nauheim baths, and had obtained very satisfactory results, but it was necessary in this class of case to maintain the baths at a temperature higher than usual, ranging from 93° to 95° F., and to give the still baths and not the carbonated. The fact that many medical men were under the erroneous impression that a Nauheim bath was necessarily a carbonated bath, and therefore started a course with CO_2 baths, was responsible for many failures where such methods were tried.

LIVERPOOL MEDICAL INSTITUTION.

Pathological Specimens of Tuberculosis.—The Rôle of Tuberculosis.—Pulmonary Tuberculosis in Children.

A pathological meeting of this society was held on March 26th, Professor R. J. M. Buchanan, Vice-President, being in the chair. The meeting was devoted to tuberculosis, and an extensive exhibition of specimens was shown of tubercle as it affects the human body, as it occurs naturally among animals, and the lesions which are produced experimentally in animals.

Mr. C. Thurstan Holland showed a complete series of radiographs of lesions in all parts of the body.

Dr. Edgar Stevenson, Mr. R. E. Harcourt, and Professor Buchanan exhibited specimens and illustrations of Tuberculosis of the Eye.

Mr. K. W. Monsarrat, Professor E. E. Glynn, Dr. W. Hanna, and Dr. Nathan Raw showed lesions of both man and animal, while Dr. Raw also showed cultures of human, bovine, and avian tubercle bacilli.

Professor H. Briggs exhibited specimens of five cases of Tuberculosis of the Uterus and Uterine Appendages.

The exhibition of local material was enhanced by the loan of a series of specimens of human and animal tuberculosis prepared by Professor S. Delépine by his special arsenious jelly method.

Dr. A. Stanley Griffith (Cambridge) lent specimens demonstrating the experimental lesions produced in the larger animals.

Dr. Eastwood and Dr. F. Griffith lent a complete series of cultures of the various types of bacilli, a series of rabbits' lungs showing the "rabbit test" of virulence, and also specimens of lesions in larger animals, natural and experimental.

Dr. Raw read a note on the Rôle of Tuberculin in Tuberculosis, and confined himself to the pathological effects of tuberculin when injected into the human body. He gave his methods of dosage and his reasons for using opposite strains of tuberculin in his "bovine" and "human" cases. His conclusion after extensive experience was that tuberculin was good in localised tuberculosis, but not if there were secondary infections.—Dr. T. R. Bradshaw thought that tuberculin would never revolutionise tuberculosis.—Dr. G. A. Crace-Calvert found that patients receiving tuberculin showed distinct improvement in many ways—improvements which were not so visible in patients not so treated.—Professor Buchanan thought that the multiplicity of tuberculins on the market led to confusion.—Dr. Raw replied.

Dr. S. W. McLellan read a paper on the Incidence of Pulmonary Tuberculosis in children. He pointed out the danger of error arising in statistics from the personal factor of the collector, and how this might be controlled. The methods of investigation were considered, and also the fallacies of the various specific tests. The question of glandular and pulmonary disease was gone into, and how the former predominated. He considered that pulmonary tuberculosis in children was by no means so common as was generally supposed, and suggested various means whereby the diagnosis might be checked. He analysed 162 cases which had been personally investigated at the Liverpool Chest Hospital, all of which had been previously diagnosed as phthisis, and traced their after-history, pointing out that cases of chronic fibroid pneumonia, or bronchiectasis, frequently gave all the so-called classical signs of phthisis, but that the process of these diseases was very chronic and no tubercle bacilli were ever found in the sputum.—Dr. C. Rundle discussed the paper, saying that in his opinion anatomical diagnosis was better than clinical.—Dr. J. R. Logan had used Moro's test with success. In his opinion tuberculosis was common in children and the majority recovered.—Dr. C. J. Macalister, Dr. N. P. Marsh, Dr. H. Armstrong, Dr. W. B. Warrington, and Professor Buchanan agreed that pulmonary tuberculosis was rare in children.—Dr. McLellan replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Exhibition of Specimens and Reports of Cases.—Malaria as a Complication of the Puerperium.—The Use of Pituitary Extract in Labour.

A meeting of this section was held on March 6th, Dr. M. J. Gibson, the President, being in the chair.

Dr. Alfred J. Smith showed a specimen of Fibromyoma presenting unusual features. The patient consulted him for painful tumour in the lower abdomen. On opening the abdomen difficulty was experienced owing to adhesions between the tumour and the abdominal walls, and it was necessary to open higher up. It was then found that there was a coil of small intestine attached to the top of the tumour. Peculiar peritoneal folds were found hanging from the tumour simulating intestine.

The President reported a case of Combined Intra- and Extra-Uterine Pregnancy. The patient, aged 36, married 14 years, had had seven children and two abortions. The youngest child was now three years old. She aborted at the fourth month in September, 1912, and again at the sixth month in August, 1913. On Nov. 26th she stated that she had not menstruated since Sept. 17th. Pain, not severe, in her right side low in the abdomen and extending to her back had begun about ten days previously. No bleeding. Examination revealed an enlarged, softened uterus, acutely anteflexed. To the right of it was a very tender, mobile, non-pulsatile tumour of the size of a small hen's egg. The patient came into hospital three days afterwards. She had had very severe pain in the interval. Periodical attacks of acute pelvic pain continued. A tubal pregnancy complicating an intra-uterine pregnancy was diagnosed. On opening the abdomen free blood was found in the pelvis with clotted blood in Douglas's pouch, an enlarged tube, and a pregnant uterus. The tube was removed, and the patient made an uninterrupted recovery for two weeks, when she expelled the other ovum. She left the hospital ten days later. Whether the tubal pregnancy was due to the second ovum becoming impregnated after the first, and consequently finding its passage to the uterus impeded by the decidual reaction in the tube, was an interesting question.

The President also reported a case of Early Tubal Pregnancy and one of Unruptured Interstitial Tubal Pregnancy.—Dr. E. Hastings Tweedy wished to know what was done with the tube in the case of interstitial pregnancy. He presumed the tube was broken in order to clear out the ovum.—The President, in replying, said that as regarded the unruptured interstitial pregnancy he did not interfere with the tube at all; the incision was made low down, and the ovum turned out of its capsule. He did not believe that he closed the interstitial portion of the tube when suturing the capsule. With regard to the combined intra- and extra-uterine pregnancy, there was no doubt whatever about the tubal pregnancy, as the microscopical examination proved the presence of a recent ovum.

Dr. Bethel A. Solomons read a note on Malaria as a Complication of the Puerperium, in which he commented on the scarcity of cases to be found in the literature. The chief case which had come under his notice was that of an Indian official's wife with a history of an attack of malaria two years previously. The confinement was complicated, and there was an extensive laceration of the perineum and vagina. The diagnosis between sepsis and malaria was extremely difficult. The absence of growth after lochia and blood had been cultured, and the presence of the plasmodium malariæ in the blood clinched the diagnosis. The patient recovered after a stormy puerperium.—Dr. Tweedy said he had seen two or three cases of malaria in his practice, and he also saw one of Dr. Solomons' cases, in which he suggested malaria as a possible cause of the temperature. He emphasised the importance of taking uterine cultures early. With a temperature like that in the case cited by Dr. Solomons, if the culture was negative no time should be wasted in getting a specimen of the blood, and he advised that a good quantity of blood should be taken. He was convinced that the case was not one of pure malaria, but that some septic infection was associated with it.—Dr. Solomons, in reply, said that with reference to Dr. Tweedy's suggestion that the malaria was not the only cause of the temperature, he considered that the vaginal condition possibly aided in keeping up the temperature for a longer period than in an ordinary case of malaria.—Replying further to questions by Dr. STEVENSON, Dr. V. J. MCALLISTER, and the PRESIDENT, he said that Dr. R. J. Rowlette had examined the blood, but the variety of parasite was not stated. It would be interesting to know if the baby, which was a particularly fine specimen with no abnormality, was immune. The mother had been healthy during the whole pregnancy.

Dr. D. G. MADILL and Dr. R. M. ALLAN communicated a paper on the Use of Pituitary Extract in Labour, in which they reported the results of 147 cases. Referring to its effect on the uterus, they found that the contractions resulting from the drug retained their physiological character, and they regarded this as the fundamental principle governing its use in labour cases. They had never observed a tonic contraction. The interval between pains was diminished by about one half, and the effect of the drug lasted 50 minutes. There was an earlier detachment of the placenta. Regarding the effect on the fœtus, they often noticed an effect on the fœtal heart following the injection, but the child was born healthy. They reported four cases of fœtal death which might be due to the injection of the drug. It was tried unaided in one case to induce premature labour, and in two cases in conjunction with Champetier de Ribes' bag, all being successful. They considered the second stage, with the head well through the brim, as the best time for its administration, and in most of their cases the drug was given at this time. They had good results with it in post-partum hæmorrhage in combination with ergot. Its use was contraindicated in heart lesions, but probably not in nephritis. It was a valuable adjunct in cases of placenta prævia where version had been performed. They had six instances of post-partum atony of the uterus of a slight degree.—Professor A. C. SMITH said his only experience of pituitrin was in gynæcology. He was at present using it in cases of infantile uterus and the menorrhagia of young girls. Young rats who were fed on pituitrin extract grew to great size, and their genital organs were hypertrophied, and it was for this reason that he was using it. He also mentioned its utility in connexion with intestinal stasis after laparotomy. Pituitary extract had an action on the mammary gland.—Mr. SPENCER SHEILL had given the drug intramuscularly in about 27 cases; it took eight and a half minutes to act. Was the difference between the three and a half minutes experienced by the writers of the paper and his eight and a half minutes accounted for by the difference in the site of injection? He considered the drug less effective after scopolamine morphina.—Dr. TWEEDY recommended the use of pituitrin where curetting failed to stop hæmorrhage, and suggested using it before resorting to larger operations. He disapproved of its employment in contracted pelvis, and mentioned a case of rupture of the uterus, following quickly upon the administration of pituitary extract, brought under his notice by a doctor in America. He had found half of the contents of the 1 c.c. phials sometimes produced extremely good labour contractions. He always injected half and gave the remainder if it was not effective. He did not consider that cases delivered by forceps in the Rotunda Hospital could be compared with the cases where pituitary extract was given.—Dr. SOLOMONS said that most authorities agreed that whilst the drug was useful in cases of active abortion it was useless as an abortifacient. He was surprised that there were no lacerated cervices or ruptured uteri in any of the cases, as De Lee, in the "Year Book of Obstetrics," commented on these results of the drug. Where contracted pelvis was suspected pelvimetry should be done before administering pituitrin. He had given pituitary extract with excellent effect in cases of amenorrhœa with chlorosis.—Dr. MCALLISTER said undoubtedly these preparations increased the uterine contractions, but he did not consider that the contractions preserved their physiological character, the interval between the pains becoming too short. He considered the drug at its best where there was slight obstruction. The general opinion was that it was most useful and safest for the child during the expulsion stage. He was not sure that the results from pituitrin in the third stage were as satisfactory as those from ergotin. He had found the injection of pituitrin into the uterus preceding Cæsarean section very useful. Pituitrin markedly increased excretion of urine. In cases of retention of urine after operation his experience in the Coombe Hospital showed that it was useless.—Dr. HENRY JELLETT thanked Dr. Madill and Dr. Allan for the amount of work they had performed and for the valuable results brought forward. It had been found that the use of pituitary extract in 140 cases had not been followed by any bad results. As to its increasing fœtal mortality the results brought forward were strikingly directed to prove the contrary. In a large number of cases in which forceps were applied the necessity arose out of a delay in the second stage; if pituitary extract avoided this morbidity should be lower. In ante-partum hæmorrhage he emphasised the fact that delay after the hæmorrhage was checked was beneficial to the patient though not to the child. It was unwise to hasten delivery until the woman had recovered somewhat, then pituitary extract might be of value.—The PRESIDENT said he had seen two cases in which the administration of pituitary extract during the first stage had been followed by extensive laceration of the lower uterine segment. In a case of placenta prævia it was impossible to turn the child owing to the effect of the extract. He considered the extract contra-indicated in the first stage unless contractions were feeble, the stage prolonged, and the cervix neither diseased nor friable. In the second stage with uterine inertia it was excellent; after the third stage it should be combined with intramuscular injection of ergot. He had seen much trouble result from the injudicious use of the extract. It should be used not freely but with great care, and not at all in obstruction. —Dr. ALLAN, in replying to questions, said no change was noticed in the mammary gland. In the first cases the drug was given intramuscularly, but latterly subcutaneously. When given by the former method the pains came on quicker, but by the latter the pains were more gradual and at longer intervals. They had no experience of it with scopolamine morphine. The drug was never given in post-partum hæmorrhage alone, it was always combined with ergot; neither had it been administered in cases of eclampsia. In five cases the drug had failed to be of any use. In the year previous to the use of the drug there were 106 forceps cases at the Rotunda Hospital, and during the past year when it was given there were only 56 cases. No opportunity was afforded of trying the drug in a case of accidental hæmorrhage. Syringes were sterilised by boiling, and afterwards kept in sterilised water. There was no experience in any of the cases of cervical tears. It was agreed that the best results were obtained in the expulsion period. It was not considered that the drug had any advantage over ergot in cases of Cæsarean section, and the latter was always given. The drug should be used with caution, and the fœtal heart should be carefully watched.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 20th, Mr. A. Ernest Maylard, the President, being in the chair.—Dr. Alexander MacLennan read a paper on the Simplified Operation for the Cure of Hernia in Infants. He said that while the radical cure of hernia in the adult possessed a serious morbidity and some mortality, the operation in infants practically possessed neither. In the majority of text-books herniotomy in infants was advised only in cases of irreducible or strangulated hernia, or in cases where truss treatment, properly and continuously applied, had failed to retain the hernia. But truss treatment had many disadvantages, and there was no case known where an actual obliteration of the sac had followed the wearing of a truss, while in many cases in spite of apparent cure the hernia had reappeared later. Indeed, it was practically certain that no one in later life developed a hernia who had not had since infancy a sac ready formed. That the early operation was absolutely safe had been proved by the wholesale radical treatment of hernia in infants attending the Royal Hospital for Sick Children out-patient department. The credit for the initiative in doing hernias in out-patients belonged to Dr. J. H. Nicoll, and the operation which he (Dr. MacLennan) performed was so simple that the dangers associated with the radical operation had vanished. The cases selected were infants not over 2 years, in fair general health, with mothers of average intelligence, able and willing to give a little more attention than usual to the child. If phimosis was present the child was circumcised at least one month before the proposed radical operation; though in exceptional circumstances the circumcision and radical cure might be done at the same sitting. Preparatory to operation food was withheld for three hours, but the bowels were not interfered with. Chloroform was the anæsthetic employed. An incision three-quarters of an inch long was made over the internal ring, and the sac when reached and freed was treated as in Macewen's operation. No deep sutures were used. The superficial wound was closed by one or two silkworm sutures, and dressed by a roll of gauze made to cover little more than the wound and retained in position by a piece of adhesive rubber plaster. Elaborate dressings were quite unnecessary, and only annoyed the infant. After a week the child was brought again to the dispensary to have the stitches removed. Done rapidly through a small incision, with the minimum of manipulation, dissection, and stitching, and without violence to the anatomy, this operation entailed little tax on the vitality of the child, and, indeed, caused less distress than a simple circumcision.—Dr. T. P. Grant (for himself and Dr. Matthew J. Stewart of Leeds) read a short note on Myeloid Tumours of Tendon Sheaths, with report of a case. As such tumours occurred with much greater frequency in the hands than elsewhere, it was supposed that slight and frequently *repeated trauma might be of some etiological importance.* The chief diagnostic points were that the tumour was small and slowly growing, painless in the earlier stages, and, unless it attained a considerable size, interfered but little with the movement of the tendon. It was freely movable on the bone, and the skin was moved equally freely over it. In the great majority of cases these tumours were of very low malignancy, and the method of treatment in the first instance should be by local removal only. The case reported was that of a female, aged 54, who had a tumour about the size and shape of a haricot bean on the radial aspect of the second phalanx of the left ring finger. Eight months before this appeared she had received a stab from a knitting needle exactly at that spot. The tumour was excised, and on microscopic examination was found to be largely fibro-sarcomatous in structure, containing, scattered throughout it, giant cells which stamped the growth as myeloid. It showed evidence of degenerative change apparently of a fatty nature.—Dr. Archibald Young described a case of Fracture of the Carpal Scaphoid and showed the patient and X ray photographs. The case was remarkable in that the bone was divided by a vertical break into a right and a left half, and one of these was again divided horizontally into a dorsal and a palmar fragment. The injury which caused the fracture had apparently been so trifling as to have escaped the patient's notice at the time. Dr. Young, with Dr. J. Shaw Dunn, also showed a large Sacro-coccygeal Teratoma removed from an infant, aged 11 months, with relative photographs, radiograms, and microscopic sections. These latter showed tissues derived from all three primitive layers —epiblast, mesoblast, and hypoblast.

North of England Obstetrical and Gynæcological Society.—A meeting of this society was held in Sheffield on March 20th, Dr. J. H. Willett (Liverpool), the President, being in the chair.—Dr. D. Dougal (Manchester) described a specimen of Allantoido-angiopagous Twins. One twin was a typical anencephalic monster, the other belonged to the rarer group of amorphous fœtuses. Both twins communicated with one another through the umbilical vessels near the edge of the common placenta.—Dr. H. Clifford (Manchester) showed a specimen and gave details of a case of Ectopic Pregnancy occurring in the stump three months after ovariotomy. In the meantime the other ovary, which at the first operation was apparently healthy, had become cystic, the combined swellings giving rather the impression of an ordinary pregnancy on examination without an anæsthetic.—Mr. Miles H. Phillips (Sheffield) reported a case of Double Ovarian Tumour, in which acute abdominal pain during the third week after an ovariotomy was due to torsion of the pedicle of a second ovarian cyst. The patient was 68 years old and very feeble. At the first operation a huge ovarian cyst, containing 30 pints of fluid, which had extended deeply into the left broad ligament, was removed with the uterus. The second cyst, measuring 5 by 4 by 4 inches, was not seen, apparently on account of its long pedicle, of over 5 inches, and the Trendelenburg position. The second operation was easy, and the patient made a good recovery.—Dr. Arnold W. W. Lea (Manchester) related a case of a patient with a large Ovarian Cystoma causing severe symptoms.—Mr. D. Gray Newton (Sheffield) showed a case of Ovarian Tumour accompanied by ascites and pleural effusion, clinically pointing to malignancy but pathologically proving a cysto-adenoma.—Dr. R. Favell (Sheffield) exhibited a large Fibromyoma of the Uterus undergoing sarcomatous transformation in parts. The patient was aged 47 years, and had noticed the swelling increase in size rapidly for 12 months.—Dr. W. E. Fothergill (Manchester) in Prolapse with Hypertrophy of the Cervix had adopted a further modification in the technique of anterior colporrhaphy combined with amputation of the cervix. Instead of removing a portion of the anterior vaginal wall as one piece and the cervix as a separate piece he now removed a triangular portion of the anterior vaginal wall together with the cervix in one piece. This method gave very neat immediate and very satisfactory remote results.—Mr. W. W. King (Sheffield) showed three specimens of Blighted Ova of a few weeks gestation which had been passed by three different patients shortly after the delivery of full-time children. He regarded them as examples of superfœtation, but he especially emphasised their medico-legal importance.

Ulster Medical Society.—A meeting of this society was held in the Anatomical Laboratory of the Queen's University of Belfast on March 26th, Mr. A. B. Mitchell, the President, being in the chair.—Professor J. Symington showed and explained the following exhibits: (1) A model of the Abdomen and Pelvis made by Miss Rea from a series of horizontal sections; (2) a series of specimens of Tubal Pregnancy; (3) a case of V-shaped Palate, with irregularity in the position of the incisors, cleft palate, defective nasal septum, and hypertrophied inferior and middle turbinals; (4) specimens to illustrate Differences between the Sternal and Axillary Borders of the Mammary Gland; (5) Cowper's Glands exposed *in situ;* (6) Accessory Sphincters of the Bladder; (7) series of sections of the Vagina.—Mr. P. T. Crymble exhibited: (1) Reconstruction of the Intestine and Urinary Bladder of a man aged 50 years; (2) reconstruction of the Stomach and Intestine of a girl, aged 20 years, showing visceroptosis; (3) horizontal sections of an Abdomen distended with Gas; (4) an Abdomen in which the jejuno-ileum, cæcum, and ascending colon possess a common mesentery; (5) Dilatation of the Colon, associated with a kink at the splenic flexure; (6) a Posterior Dissection of the Abdomen which exposes the anterior relations of the kidneys.—Dr. H. P. Malcolm showed: (1) Section through a Dislocated Shoulder; (2) Bilateral Fusion of the Inferior Turbinal with the Floor of the Nose; (3) specimen of Bilateral Accessory Renal Arteries.—Dr. R. J. McConnell exhibited: (1) Specimens illustrating the Anatomy of the Gall-bladder; (2) Dislocation of the Ulnar Nerve; (3) specimen of Retracted Nipple.—Dr. J. E. MacIlwaine showed a beautiful specimen of Auriculo-ventricular Bundle in a Bullock's Heart, demonstrated by injection of Indian ink, and he communicated a short paper showing a method of demonstrating the auriculo-ventricular bundle.—Mr. Crymble read a paper on Anatomical Factors in Abdominal Percussion.—Dr. Malcolm read a communication on the Topographical Anatomy of the Spleen.—Dr. McConnell read a short paper on the Anatomy of the Gall-bladder and Bile-ducts, and he also showed lantern slides of an Intussuscepted Appendix.

Birmingham and Midland Hospital for Women.—In their annual report the board of management state that the number of new out-patients last year was 4633, an increase of 160, and the total number of cases treated, new and old, was 21,502. In-patients numbered 1272, an increase of 167, and of the total number 152 were paying patients. The committee acknowledge with pleasure the success of the Gertrude Myers Home at Cleeve Prior. During the year over 100 patients had been admitted, the average stay being three weeks. No cost of management had fallen upon the hospital funds, its upkeep being provided entirely by patients and subscribers. The statement of accounts showed an adverse balance of £2525. At the Maternity Hospital 532 patients were admitted as compared with 537 the previous year. The need for accommodation for pupil midwives had arisen, and premises in Corporation-street had been taken and fitted up for 25 pupils at a cost of £1175.

Reviews and Notices of Books.

The Sensory and Motor Disorders of the Heart: their Nature and Treatment.

By ALEXANDER MORISON, M.D. Edin., F.R.C.P. Edin. Senior Physician to the Great Northern Hospital; Physician in Charge of Heart Cases to the Mount Vernon Hospital for Consumption and Diseases of the Chest. London: Baillière, Tindall, and Cox. 1914. Pp. 261. Price 7*s.* 6*d.*

THE title of the work now before us sufficiently indicates its contents, and Dr. Morison has succeeded is setting forth some interesting facts and suggestions as to the nature and treatment of sensory and motor disorders of the heart.

The more modern investigations in regard to diseases of heart have been largely based upon mechanical methods of examination, and much useful knowledge has thus been gained; also ideas on the nature of cardiac sensibility and motion have had to undergo considerable change, owing to the result of the researches which have been carried out on the anatomy and physiology of the heart. Dr. Morison states that the clinical methods he has chiefly employed are those of inspection, palpation, percussion, auscultation, and pathological investigation, but the graphic method has also been used to illustrate some points. He does not emphasise the value of the tracings obtained by the electrocardiograph. Dr. Morison considers at length the nervous mechanism of the heart and the share which it takes in relation to the sensibility and movement of the heart. In the chapter on the nerve control of cardiac action he gives an instructive account of the researches which have been made by various observers. He points out that there is no doubt that the heart contains within itself the mechanism and incentives to sinu-auriculo-ventricular action, and also remarks that it seems reasonable to believe that stimulus production in cardiac muscle may be provoked or checked by the nervous system, that the conduction of muscular movement from one part to another may also be influenced by it, and that the tone of muscle may certainly be augmented or depressed by the action of the nerves supplying the muscle.

The portion of the book devoted to the sensory disorders of the heart will be found to afford interesting reading. Dr. Morison's lectures on cardiac pain, which have already appeared in our columns, form the basis of his teaching. The observations on the clinical history of cardiac pain have evidently been carefully thought out, and are founded on practical considerations. The classifying the conditions which may bring about cardiac pain is by no means easy. The terms "false" and "true" convey little meaning, and the degrees of severity or fatality denoted by such words as "gravior" and "mitior" are not much more enlightening. But we do not think that the use of the terms "vaso-motor," "arterial," or "coronary" can be dismissed so easily. He suggests a classification which endeavours to give a local habitation and a name to phenomena which cannot yet be explained with scientific precision. Although this may be a step in the right direction, yet the plan which he has evolved is too elaborate, and it will be necessary to render it less cumbersome before it will be generally adopted. The diagnosis of cardiac pain is expressed in terms which are rather involved, and careful reading is required before the author's meaning can be perceived, when his reasoning is found to be sound.

In discussing the disorders of cardiac motion an elaborate classification is also adopted, scientifically correct perhaps, but too complicated for practical purposes.

The chapters on treatment are generally in accordance with modern views, and Dr. Morison ventures to hope that some mechanical impediments to the action of the heart which are beyond the power of the physician to deal with may, by the combined efforts of the physician and surgeon, be more successfully treated now and in the future than has hitherto been possible.

This book is an interesting study of cardiac disease, expressing not only the present state of knowledge on the subject, but also original views which are well worthy of consideration.

Psychanalysis, its Theories and Practical Application.

By A. A. BRILL, Ph.B., M.D., Chief of the Neurological Department of the Bronx Hospital, New York, &c. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 337.

Dr. Brill's name is known to English psychiatrists as the translator of several of the more important works of Professor Sigmund Freud, of Vienna. He has now written a book the main object of which is to present the practical application of Freud's theories in one volume, in the hope thereby to remove certain erroneous conceptions about psychanalysis, and at the same time to stimulate interest in Freud's own contributions to the subject.

The book is written from a frankly Freudian standpoint, as is natural in one who has been instrumental in popularising Freud's doctrines, and it is more explanatory and expository than critical. Much of the material of the book is purely illustrative, and much is merely reminiscent of the teacher's views. There is throughout a tacit assumption that the reader is in sympathy with the author's interpretation of the phenomena of various cases and of his material as a whole, for little serious attempt has been made to persuade the critical reader of the correctness of the explanations. For instance, it is stated that the "almost universal" masturbation of infants serves "to prepare the genitals for their future function." Again, it is said there is no accidental forgetting, and that there is always a purpose in forgetting. The typical symptoms of neurasthenia are stated to be "headache, spinal irritation [whatever that may mean], and dyspepsia with flatulence, and constipation." These are always due to "somatic sexual injuries." Once more, "all great actions and accomplishments, heroic or commercial, are generally done for the purpose of pleasing some woman."

It is really impossible to take these and other of the author's generalisations seriously. Yet the book is full of them, so that if Dr. Brill meets with an unsympathetic reader we are afraid he is not likely to convince or even to impress. A book of this sort has a tendency to move in certain circles only. Those who can follow Freud's doctrines in their entirety will approve of the aptness of much of Dr. Brill's illustrations; those who are sceptical are likely to remain so. The book would not have been impoverished if one or two stories, intended to illuminate, had been omitted. As Dr. Brill holds that "mistakes in printing" are due to direct or indirect association with something repressed, and illustrates the point by an allusion to the "wicked Bible" of 1631, it may be pointed out that there is a mistake in printing in the very passage in which he makes this reference.

Die Morphologie der Missbildungen des Menschen und der Tiere.

Herausgegeben von Dr. ERNST SCHWALBE, O.Ö. Professor der Patholog. Anatomie, Rostock. III. Theil, XI. Lieferung. 1. Abteilung, 5 und 6 Kapitel. *Die Missbildungen des Kopfes.* Mit 65 Abbildungen im Text. Jena: Gustav Fischer. 1913. Pp. 205-270. Price 5 marks.

UNDER the title of Malformations of the Head, dealt with in this part of what is now an extensive handbook, the following three groups of malformations are differentiated by E. Schwalbe and H. Josephy. All three groups are morphologically characterised as bilateral symmetrical malformations in which the median placed parts of the head either are wanting or at least are very imperfectly developed. I. Cyclopean and arrhinencephalous forms, in which the malformation affects the anterior parts of the brain, eyes, and nose. II. Otocephalous forms, in which the ear and mouth are malformed. The combination of the forms I. and II. is by no means rare. III. Triocephalous forms, a small group which has certain relations to II. The most striking visible character of the cyclops is that it has, or appears to have, only a single centrally placed eye, but its duplex constituent is usually readily distinguishable. It occurs at the root of the nose.

To Group I. about 40 pages are given. First, cyclopean characters in man and animals are described, then the morphological characters of the brain and eye are described, and illustrations given of cylopean forms in man, the goat, and pig. The "proboscis," the homologue of the nose—a double organ—is described and well illustrated. The absence of the rhinencephalus—a phenomenon described by Kendrat as arrhencephalic—is described, and the close relationship between this and the cyclopean form pointed out and illustrated. The causes of these two conditions are discussed as they occur in fishes, birds, and other animals. Otocephalic and tricocephalic forms are dealt with by H. Josephy in about 20 pages.

The part before us gives a compact descriptive account of the subjects with which it deals. The number, excellence, and variety of the illustrations will prove most useful even to those who do not wish to dip deeply into the descriptive text, which, however, is singularly clear and expressive.

Map Scheme of the Sensory Distribution of the Fifth Nerve (Trigeminus) with its Ganglia and Connections.

By L. HEMINGTON PEGLER, M.D. Edin., M.R.C.S. Eng., Senior Surgeon, Metropolitan Ear, Nose, and Throat Hospital, &c. Printed in 15 colours, and mounted on rollers for hanging up (size 4 × 5 feet), or folded in cloth cover (size 8⅓ × 11 inches). London: Baillière, Tindall, and Cox. Price 21*s.* net.

Dr. Pegler's map of the sensory distribution of the fifth, or trigeminal, nerve is very well done. There are no fewer than 315 named nerves and branches in the map, which is intended to aid the student in his work, both reading and dissection, on the complex trigeminal, and also to assist the clinician to understand the numerous referred pains or other symptoms which arise as a sequel to disease in such organs as, say, the nose, ears, eyes, or teeth. An immense amount of labour has been devoted to ensuring accuracy in the map, and professed anatomists and others have contributed to Dr. Pegler's scheme, so that it may be said to have the imprimatur of anatomist as well as of surgeon. There is a useful inset to the map containing a representation of the central connexions of the fifth nerve. Accompanying it is a booklet containing a series of analytical tables indispensable to the useful study of the map.

The map should at once take its place as a valuable addition to the teaching material of anatomical schools and medical and surgical clinics; its large size and its clear and distinctive printing enhance its usefulness.

Butterworth's Workmen's Compensation Cases.

Vol. VI. (New Series.) Edited by His Honour Judge RUEGG, K.C., and DOUGLAS KNOCKER, Esq. London: Butterworth and Co. 1913. Pp. 1193. Price 7*s.* 6*d.* net.

THIS annual issue gives full reports of the decision upon appeal of points of law arising under the Workmen's Compensation Act, and contains much that might upon occasions be found useful by medical men called upon to give evidence in arbitrations as to workmen's compensation, as well as by medical referees and others. It must be remembered, however, that it contains decisions of questions of law only, and that from reading reports of cases appealed upon medical men can only acquire a general knowledge of the points which are material to the establishment of a claim. Their evidence goes to prove the facts. The county court judge sitting as arbitrator comes to a decision as to the facts and applies the law, after which the Court of Appeal may be asked to decide whether he has rightly directed himself as to the law, and (as a general rule) whether there was evidence to support the award. Many of the cases under the Workmen's Compensation Act recorded in the present volume have already been referred to in THE LANCET, but of those of medical interest not thus commented upon may be noted Simpson *v.* Byrne, an Irish case, in which an arbitrator was held to be justified in terminating an award where a workgirl suffered from the wasting of the muscles of her arm, alleged to be due to an accident, but where medical evidence showed that her refusal to use her arm was the real cause of its condition. Another appeal heard in the Court of Session, Scotland (O'Neill *v.* John Brown & Co., Limited), arose out of the refusal of a workman in receipt of compensation to submit to the removal of the painful stumps of two toes. Two medical men advised that it would be useless for him to do so, and three recommended the operation, which the sheriff substitute found to be reasonably certain to effect its object, holding as the result of this that the workman's incapacity was due to his refusal and not to the accident. The court here again held that there was evidence to support the finding.

It must not be supposed that the rather alarming bulk of the volume under review (over 1000 pages) is due entirely to the elucidation of the law of workmen's compensation by courts of appeal. In it are now included cases under the National Insurance Act and others relating to general insurance other than marine. Under the former heading will be found recorded the learned judgments delivered by the Court of Appeal in Heard *v.* Pickthorne, the case in which an Approved Society refused to accept from its members, for the purpose of sickness benefit, the certificates of medical men not upon the panel.

Die Chronischen Erkrankungen der Hinteren Harnröhre.

Von Dr. ERICH WOSSIDLO, Berlin. Mit 82 meist farbigen Abbildungen auf 19 Tafeln. Leipzig: Dr. Werner Klinkhardt. 1913. Pp. 155. Price, paper, 10 marks; bound, 11 marks.

THIS is a careful study of the affections of the posterior urethra. It is now fully recognised that the posterior urethra is sufficiently different from the anterior portion of the tube to justify a separate consideration as regards diagnosis, prognosis, and treatment.

In this work the author has described the anatomy of the part, the modes of investigation of the urine and other secretions concerned in the examination of this part of the urethra, the use of the endoscope and of other instruments. Then follow chapters on urethritis posterior in its various forms and of other diseases of the posterior urethra; then comes an account of the methods of operative manipulation; and, lastly, there are chapters on prostatitis and prostatic hypertrophy. The book is evidently the product of one well acquainted practically with the treatment of the diseases of the posterior urethra, and he has produced a work which should prove useful to those who wish to practise genito-urinary surgery. Not the least valuable part of the book is the series of coloured illustrations of the pathological and normal conditions described.

Controlled Natural Selection and Value Marking.

By J. C. MOTTRAM, M.B. Lond. London, New York Bombay, and Calcutta: Longmans, Green, and Co. 1914. *Pp.* vii.–130. Price 3*s.* 6*d.* net.

IN this volume Dr. Mottram propounds, but does not attempt to prove, a corollary to the theory of natural selection. He starts from the fact that when individuals are united into societies, those societies which are organised and differentiated in such a way as to have the advantage over competing societies will be likely to survive, and thus their advantageous methods of organisation or differentiation will be perpetuated. He then argues that individuals of different classes within each society have different values, and thus that any arrangement which ensures that the less valuable are killed rather than the more valuable will be of advantage to the society. It is under circumstances such as these that natural selection will be "controlled." The author claims that on his theory the origin of secondary sexual characters can be explained more easily than on the theory of sexual selection, which he regards as a weak spot in the Darwinian hypothesis. It cannot be said, however, that his explanation is of a very satisfactory kind. It may be stated briefly as follows. The female is more valuable than the male, because one male can fertilise many females; therefore the advantage that secondary sexual characters bring is that the male is sacrificed on behalf of the female. "Males and females are associated together during life, and especially during the breeding season, when the difference in colour is greatest and when their difference in value is highest. Therefore, according to the theory, the conspicuous colour of the male serves to control natural selection in such a way that the less valuable male will be killed in preference to the more valuable female." This sounds apparently reasonable enough, but the author regards the courtship display, or, as he prefers to call it, the "precopulatory display," of the male as evidence in favour of the correctness of his view. It is here that his explanation becomes very difficult to follow. Although we can conceive that it might be advantageous that the male rather than the female should be killed during copulation, it is hardly conceivable that an elaborate device for destroying the male just before copulation should, if effective, lead to anything but the extermination of the species.

Altogether it may be said that Dr. Mottram's reasoning about natural selection is unconvincing, because he starts from premises to many of which we cannot assent. For example, he asserts that a species completely fills and perfectly fits its environment; that "it is impossible to conceive of two species occupying the same environment, because we cannot conceive of two species, which being different in structure are yet similar in function," and that the colour of an animal if not protective must be purposely conspicuous, as it cannot be indifferent.

Die Wassermannsche Reaktion, mit besonderer Berücksichtigung ihrer klinischen Verwertbarkeit. (*The Wassermann Reaction, with Special Reference to its Clinical Value.*)

By Dr. HARALD BOAS, Privat-docent at the University of Copenhagen, &c. With a Preface by Professor WASSERMANN. Second enlarged and improved edition. Berlin: S. Karger. 1914. Pp. 242. Price, paper, 7.60 marks; bound, 8.80 marks.

THE Wassermann reaction has now become so firmly established as a method of clinical diagnosis that a separate monograph may fairly be devoted to a consideration of its technique and of the comparative value of the modifications introduced by subsequent experimenters. Dr. Harald Boas's work will therefore meet with a warm welcome from both clinicians and laboratory workers.

The first chapter is devoted to a historical retrospect of the discovery of the test, first set forth in a brief article by Wassermann, Neisser, and Bruck in 1906, and of the early criticisms and trials to which it was subjected before obtaining general acceptance. In the second chapter the technique is put out in detail, the preparation of the antigen, amboceptor, complement, and so forth being explained, as well as the method of performing the test and the necessary controls. Various modifications are also discussed, but Dr. Boas adheres very closely to the original procedure so far as his own recommendations go, though he prefers an alcoholic extract of human heart to the original extract of syphilitic organs in salt solution. The different precipitation reactions which have been used as substitutes for the Wassermann test are also discussed in detail. The third chapter deals with experiments which have been made to ascertain the presence or absence of the reaction in diseases other than syphilis, from which it appears that the test may be positive in a certain percentage of cases of scarlet fever, but that this is a transitory phenomenon and of little practical importance. The reaction may also be positive in febrile malaria, in nodular leprosy, in framboesia, and in patients who have recently had an anæsthetic. Such exceptions to the rule that a positive Wassermann reaction indicates syphilitic infection are of little weight. In syphilis itself the reaction may not appear until just before the roseolar eruption, so that a negative result in patients suffering from a chancre is of no value in excluding syphilis. In the secondary stage the reaction is constant in the serum if the patient has not been treated for the disease, but the cerebro-spinal fluid does not generally exhibit it apart from involvement of the nervous system. In tertiary syphilis the reaction is constantly present in the serum if the patients have not been treated with specific remedies, and in cases of disease of the central nervous system the cerebro-spinal fluid may give a positive reaction, but does not always do so. In untreated cases of tabes dorsalis the reaction is constantly present in the serum, less constantly in the cerebro-spinal fluid, while in dementia paralytica the serum constantly reacts positively, and the cerebro-spinal fluid also, in over 90 per cent. of cases. On the other hand, the test is of little value for the recognition of congenital infection. The relationship of the phenomenon to specific treatment by mercury and salvarsan is somewhat complicated, for the reaction may disappear as a result of such procedures, or if previously absent or weak may become positive or more marked, the appearance of a positive reaction after a dose of salvarsan being analogous to the exanthem which sometimes follows this procedure. Other points noted are that a positive reaction persisting after treatment threatens a relapse, and that so long as the test remains positive the patient must be regarded as syphilitic. An exhaustive bibliography extends over 80 pages.

The book constitutes an excellent and authoritative account of the important phenomenon with which it deals, and deserves careful study by all who are called on to carry out the procedure in the laboratory or to estimate the clinical importance of its presence or absence as bearing on the vital problems of diagnosis and prognosis.

A Text-book on Gonorrhœa and its Complications.

By Dr. GEORGES LUYS, late Assistant to the Urological Clinic, Hôpital Lariboisière, Paris; Prizeman of the Faculté de Médecine, Paris. Translated and edited by ARTHUR FOERSTER, M.R.C.S. Eng., L.R.C.P. Lond., late Resident Medical Officer, London Lock Hospital. With *200 illustrations and 3 coloured plates. London:* Baillière, Tindall, and Cox. 1913. Pp. 384. Price 15*s.* net.

THE times have changed greatly since all that was known about gonorrhœa was contained in a few pages of the ordinary text-books of surgery. Then this disease was regarded as little more than a local affection of the urethra, occasionally giving rise to a troublesome form of rheumatism or a severe conjunctivitis. Now we look upon the urethritis as probably the least important of the manifestations due to the gonococcus, for we have recognised that this micro-organism is responsible for many much more serious diseases. The fact that a large volume like that before us, containing nearly 400 pages, has been written dealing only with gonorrhœa and its complications is surely adequate proof that this disease is being estimated at its real value. Especially important is the fact that the gonococcus is the cause of many of those conditions in women which cause sterility and chronic invalidism.

It is impossible to overrate the importance of early and thorough treatment of gonorrhœa, and therefore medical men have need for more instruction in this matter than is contained in the ordinary works on surgery. They cannot have a more suitable book than this, which contains a very full and satisfactory account of the disease in its various manifestations. It describes the treatment that should be adopted and mentions the precautions that are necessary. The author is well qualified to speak on this subject, and he has succeeded in writing a book which should prove of great service to those who have to treat this protean disease. The translation has been excellently done, and the additional notes which have been made by the translator are apposite and judicious.

The Practice of Urology; a Surgical Treatise on Genito-urinary Disease, including Syphilis.

By CHARLES H. CHETWOOD, M.D., LL.D., Professor of Genito-urinary Surgery, New York Polyclinic. Illustrated. London: Baillière, Tindall, and Cox. 1913. Pp. 816. Price 21*s.* net.

THE increasing number of works devoted to the surgery of the genito-urinary system is a clear indication of the broadening of the interest taken in this group of diseases. The establishment of genito-urinary clinics has also done much to draw the attention of the student and the practitioner to the subject, though up to the present in this country few of these special clinics exist.

Dr. Chetwood has succeeded in putting before the medical public in the present work a very readable treatise on this important branch of surgery, though the title does not accurately describe the contents of the volume; for, in the first place, it contains several subjects which are not correctly included under the name of urology, though doubtlessly they are always treated by "urogenital surgeons"; and in the second place, no reference is made to the diseases of the urinary apparatus of the female, though so far as the title goes these should be included. However, this is more a question of name than of anything else, and in many cases urological surgical practice is confined to the male sex.

The book is well written, the descriptions are clear, and much attention is paid to the anatomy of the parts dealt with. The illustrations are numerous, there are more than 300 of them, and in addition a number of excellent coloured plates. The figures are good, and many of them are original; we may mention that Fig. 248 appears to be inverted. The book should have a wide popularity, for it contains all that a student will need, and yet it is not burdened by superfluous verbiage.

The Psychoneuroses and their Treatment by Psychotherapy.

By Professor J. DEJERINE, Professor of the Clinic for Nervous Diseases of the Faculty of Medicine of the University of Paris; and Dr. E. GAUCKLER, formerly Interne of the Hospitals of Paris. Authorised translation by SMITH ELY JELLIFFE, M.D., Ph.D., Adjunct Professor of Diseases of the Mind and Nervous System, Post-graduate School and Hospital, New York. London and Philadelphia: J. B. Lippincott Company. 1913. Pp. 395. Price 18*s.* net.

THOSE who are unfamiliar with the original of the book under review may readily appreciate the general position of its authors as regards psychotherapy by some words used by the translator in his introduction. The fundamental postulate of Dubois's well-known work on the psychoneuroses is an appeal to the intelligence of the individual. It is conceded; nevertheless, even by his most ardent supporters, that he has not laid sufficient emphasis upon the instinctive, or, more widely speaking, the emotional side of the human machine in its psychical situations. In this book of Professor Dejerine and Dr. Gauckler is found just that emphasis lacking in the work of Dubois. The translator is amply justified in saying that their book provides us, in the best manner at present available, with that side of the human being not a little neglected by other authors. Professor Dejerine considers that psychotherapy depends wholly and exclusively upon the beneficial influence of one person on another. If he is to effect any result, the physician must be to his neurotic patient *un peu un ami.* In these words is the kernel of the authors' teaching.

No one who reads the book can fail to recognise how many neuropathic and psychopathic patients can be treated and cured without these more elaborate and detailed psycho-analyses of which so much is heard nowadays. Reasoning by itself is insufficient, but let the appeal be tinged with an emotional or personal element and its momentum at once is augmented and its curative value enhanced. The book consists of three parts—the first, which is analytical, is devoted to the study of functional manifestations; the second is concerned with a synthetic study of the mechanism of the psychoneuroses; the third part is therapeutic.

The practitioner may well be confused, if not overwhelmed, at the thought of the present-day output of psychotherapeutic literature, but if he is in doubt what to read and what to ignore let him not hesitate over the work of Professor Dejerine and Dr. Gauckler; we are confident he will at once find himself in sympathy with its point of view and soon prove its worth in his clinical experience.

Lehrbuch der Orthopaedie.

By Dr. VON ABERLE, Vienna; Dr. BADE, Hanover; Dr. VON BAEYER, Munich; Professor BIESALSKI, Berlin; Dr. GAUGELE, Zwickau; Professor LANGE, Munich; Professor LUDLOFF, Breslau; Dr. PREISER, Hamburg; Professor RIEDINGER, Würzburg; Dr. ROSENFELD, Nürnberg; and Professor SPITZY, Vienna. Edited by Professor LANGE. Jena: Gustav Fischer. 1914. Pp. 790, with 586 illustrations. Price 18 marks.

IN his introduction Professor Lange claims that the advances in orthopædics in the eight years that have elapsed since the publication of the last edition of Hoffa's text-book justify the compilation of a new volume. But quite apart from this the present volume justifies itself. Orthopædics, being very largely a matter of mechanics, lends itself to endless variations of method, works dealing with it are almost necessarily personal, and each such personal description must be of value to others. Professor Lange's own section of the book, dealing with the history of orthopædics, the cause of deformities, diagnosis, methods of treatment, the use of bandages, plaster, apparatus, massage, gymnastics and physical methods, &c., is for this reason the most interesting of the several articles, and may be recommended to all those engaged in this specialty.

Some space is devoted to statistics of deformities taken from the census of cripples in Germany organised by Biesalski in 1907, from Rosenfeld's Bavarian statistics, and from the clinics of the various authors. These show that in Germany, as in England, a large proportion of cripples are affected with tuberculous disease of the bones or joints, and that the next important cause of crippling is infantile paralysis. But the third cause comes somewhat as a surprise; it is scoliosis which appears to be far more frequent, at least in its more severe forms, in Germany than in this country.

Malformations, disturbances of growth, and processes of softening of the bones are dealt with by Professor Riedinger in an article full of valuable information, the section on rickets being especially good. Professor Ludloff on inflammatory diseases is less satisfactory; too much is attempted in the space available, and the result would have been better if more attention had been devoted to details of diagnosis and treatment of the tuberculous affections. Dr. Gaugele's account of congenital dislocation of the hip is most admirable and complete, and with one reservation the same may be said of Professor Biesalski's long section on diseases of the nervous system. Spastic paralyses obtain very full recognition, the newer methods of Förster, Stoffel, and Spitzy all receiving description; but of anterior poliomyelitis a much less complete account it given, and the methods of treatment of the paralysis in the early stage, the most important methods of all, are passed over very briefly.

Professor Spitzy writes on deformities of the spine, on the whole a full and up-to-date account. It is unfortunate that the term *habituelle Scoliose* should be used in Germany to mean what we should call static scoliosis, and to include both postural and fixed curves, and that by *statische Scoliose* should be indicated a scoliosis due to tilting of the pelvis. But these are differences of international nomenclature which it is difficult to remedy. Professor Spitzy's illustrations of Abbott's method of treatment scarcely give a real representation of the technique. The remaining articles are by Dr. v. Baeyer, on spondylitis; Dr. Rosenfeld, on deformities of the upper extremity; Dr. Bade, on deformities of the lower extremity; and the late Dr. Preiser, on deformities of the feet.

Handbuch der Vergleichenden Physiologie.

Bearbeitet von HANS WINTERSTEIN in Rostock. 39. Lieferung. Band III., Physiologie der Atmung. Zweite Hälfte. Seiten 641-756. Band IV.: Physiologie der Reizaufnahme. Seiten 977-997. Schluss, Titel, und Inhaltsverzeichniss. 1913. 40. Lieferung. Band III.: Physiologie des Energiewechsels. Zweite Hälfte. Seiten 787-946. Jena: Gustav Fischer. 1914. Price 5 marks each Lieferung.

IT is at times rather difficult to follow the arrangement on which the several parts of this work are issued. For example, in the part No. 39 before us we have the index and list of contents of Vol. IV., pp. 977-997, while the text itself deals with the Physiology of Respiration, by E. Babák, of Prague. The subject of respiration in fishes is continued and fully dealt with, as well as the respiratory processes in the embryo, including what is called the provisional respiratory mechanisms, and respiration in those fishes which produce their young alive—i.e., viviparous fishes. The special respiratory arrangements and their mechanisms in elasmobranchs, teleosteans, and dipnoi are then treated in detail. In the "literature" over 200 references are quoted.

The remainder of the text, about 50 pages, is devoted to respiration of the amphibians. After a general introduction the methods of investigation are described, then the means for the renewal of the respiratory medium on the respiratory surfaces — gills or skin, as the case may be. Attention is directed to the importance of the movements of the buccal and pharyngeal cavities. The ventilation of the lungs in urodela and anura is fully expounded, but to follow the exposition the reader must have an intimate knowledge of the anatomy of the muscular apparatus of the mechanism itself. The nervous mechanisms and their actions are then considered, and the text finishes with an account of the relation of the brain and spinal cord to the respiratory movements. This part will prove a valuable source of reference for students of the comparative physiology of respiration.

In No. 40 E. Godlewski, of Cracow, continues his review of the physiology of reproduction. Beginning with the question of in-breeding, the author next considers the processes that accompany impregnation and their morphological course. First the morphological changes are set forth in detail and illustrated by a large number of figures, especially from the classical observations on echinoderms and certain sea worms. The observations of Loeb on artificial parthenogenesis are described, as are the methods of producing artificial parthenogenesis employed by Delage, Shearer, and Lloyd.

The hypotheses of these several authors are stated and criticised, and the author comes to the conclusion that so far as the echinoderms are concerned, the theory of Loeb is the only one that unifies the results obtained and appears to be well based on facts. The results observed in worms, molluscs, insects, and vertebrates are then considered. The next subject dealt with is crossing and heterogeneous impregnation. Then follows an account of the action of frog's sperm exposed to radium in the development of the frog's egg. Polyspermia, which was first discovered in the selachians, but which occurs in many other animals, is next considered. It can also be produced artificially, according to O. and R. Hertwig. The consideration of the large and complex subject of heredity is then begun. First the significance of the different characters of living matter is considered. The results of chemical factors on the germ plasma are illustrated by the effects of alcohol in guinea-pigs, as shown by Ch. Stockard and D. M. Craig. Changes of cutaneous pigmentation as an acquired property are described as they occur in salamandra maculata, and this part closes with the author's account of heredity in the vegetable kingdom, which will be continued in a subsequent part.

New Inventions.

AN IMPROVED APPARATUS FOR THE INDUCTION OF ARTIFICIAL PNEUMOTHORAX.

GENERALLY speaking, the apparatus for the induction of pneumothorax is cumbrous, but I have tried to design one which shall be portable and handy.

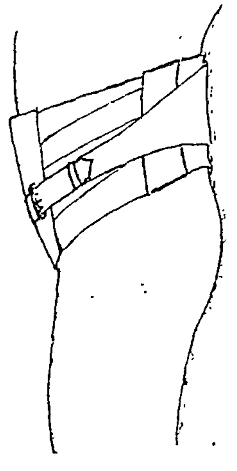
My manometer is a U-shaped glass tube which is held by aluminium clips to the inside of the door of a box. This door is entirely covered with thick felt, which serves to protect the manometer from jars and also makes the box practically air-tight. The felt is red, and the water in the manometer is coloured blue with Fehling's solution. In the back right-hand corner of the box are two pieces of wood cut to receive a graduated glass cylinder containing nitrogen, held in place by two leather straps. At the opposite corner, an inch from the door, is a vertical brass rod, on which slides, like a ring of a retort-stand, the stage for the water-bottle, which is connected with the graduated cylinder by a double syphon. Rising from the back of the stage is an upright holding the bottle by two straps, so that it cannot be upset. When the apparatus is out of use the stage with the bottle is inside the box, in contact with the left side of it, and secured to it by a third strap. The apparatus therefore requires no packing when it is carried about, except that it is well to wrap a mass of crumpled tissue-paper loosely round the gas-filters to prevent them from knocking against each other or the manometer. But the manometer, lying flat on the door of the box, is much less liable to injury than when (as in the form of apparatus commonly used) it is held in wooden supports which keep it about half an inch away from the door. When using the apparatus it is only necessary to unfasten the third strap, then the stage, with the bottle attached to it, can be made to swing round, coming entirely outside the box, so that, when necessary, the bottle can be raised until its bottom is higher than the top of the graduated cylinder. In my apparatus, not intended for hospital work, the graduated cylinder is of 500 c.c. capacity, instead of 1000 as is customary. The water-bottle is of corresponding size, and this makes the apparatus more handy and portable. The needle which I use is Saugman's, with a modification which is, I think, of practical importance. When there is reason to suppose that the lumen of the needle is obstructed with blood the stylet may be used to clean it. But with an ordinary Saugman's needle this involves some risk, because when the tap is opened to admit the stylet communication is made with the external air. In the needle made for me by Messrs. Allen and Hanbury this risk is entirely obviated. As in Potain's aspirator, the stylet passes through an air-tight stuffing-box, but in my modification it is made to screw in with an indiarubber washer.

Messrs. Brady and Martin, of Newcastle-on-Tyne, are prepared to supply apparatus made on my design.

Newcastle-on-Tyne. FREDERIC C. COLEY, M.D. Durh.

A NEW ABDOMINAL BELT FOR MEN.

THE "Isomar" surgical belt is a new abdominal support for men for use in cases where such support is desirable. The front of the belt is made of stout or fine drill, or for those who suffer with heat of cellular material, and is stiffened by three pairs of narrow vertical whalebones. It is designed to follow the direction of the fibres of the rectus abdominis muscle, while the sides, which are formed of several overlapping layers of broad elastic, follow the direction of those of the external oblique. The back is curved slightly into the waist, thus admitting of some spring above and below. Attached to the lower part of the inner surface of the belt in front is a metal plate consisting of two triangular sections with rounded corners, jointed vertically down the middle. The plate is padded with rubber to give it the necessary spring, and the whole is protected with chamois leather. This pad is most useful in cases of enteroptosis, weak abdominal walls after operation, and especially when there is a hernia, since by pressing the internal organs upwards and backwards it relieves the hernia from the downward pressure upon it. It is held firmly in place between the iliac crests and the umbilicus and pubic arch by the cinch formed of the broad but tapering bands extending from the ends of the belt on either side. One of these bands passes through the other and the ends are brought round to the front, reversed through a double cinch in front of the bottom of the pad on each side, and buckled, as shown in the illustration. There are no laces or retaining bands. The broad bandage grips the pelvis firmly and gives a decided feeling of comfort and support. The usual fault of such belts is either that they tend to ride upwards unless strapped down in some way, or that they fail to adapt themselves to the changing posture of the wearer. Having this point in mind we have had this belt practically tested for several days, and we are able to state that it fits comfortably, gives a strong feeling of support, causes no constriction anywhere, adjusts itself easily to the various movements of the body, and does not ride up, but maintains the position in which it was put on.



It is manufactured by Messrs. Morison and Stephens, 26, South Molton-street, London, W.

The Value of Albulactin in Augmenting the Colloid Element in Cow's Milk.

While the action of reversible colloids in preventing irreversible colloids from coagulation has been understood only in recent years, it has long been known that certain substances prevent the casein of milk—an irreversible colloid—from coagulating in large, thick curds when used for infant-feeding.

Recent investigations have shown that the reason why human milk forms soft, highly-comminuted flakes in the infant's stomach is because it contains much reversible or protective colloid in the shape of milk-albumin. Cow's milk contains very little of this substance, hence the large, tough curds it forms in the infant's stomach.

More than this, the problem of artificial infant-feeding is further complicated by the fact that by far the largest proportion of proteid in human milk exists as milk-albumin, while there is relatively little in cow's milk. Dr. Still's analysis proves this strikingly.

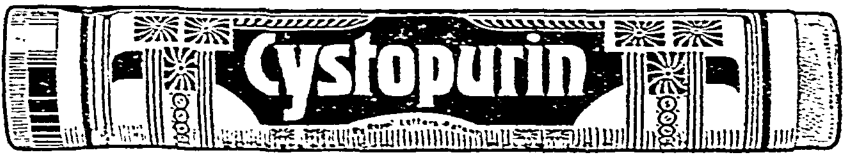
Dr. G. F. STILL'S Analysis is:

	HUMAN MILK (2% Proteid)	COW'S MILK (4% Proteid)
Casein	0·6	3·25
Milk-albumin	1·4	0·75

When cow's milk is diluted to make the total proteids agree in quantity, the child gets 1·6 per cent. of casein and only 0·37 per cent. of milk-albumin, or nearly three times more casein than it ought and only a quarter of the milk-albumin.

If the milk is further reduced to make the casein proportion correct, the milk-albumin is reduced to about one-tenth of what it ought to be. The solution of the infant-feeding problem, therefore, resolves itself logically into the addition of sufficient milk-albumin to supply the necessary protective colloid and to furnish enough easily-digested proteid. This is best done by Albulactin, which is simply pure, sterile, soluble milk-albumin, and is being extensively used by the Profession.

Samples and literature on application to A. Wulfing & Co., 12, Chenies Street, London, W.C.



A Reliable and Effective Drug in

Gonorrhœa and Septic Diseases of the Bladder.

THIS is a ***new drug,*** consisting of a double salt of Hexamethylene-tetramine with Sodium Acetate and water of crystallisation.

A Surgeon, writing in *The Lancet*, Aug. 2, 1913, says: "**Cystopurin can be employed freely, safely, and effectively in all affections of the urinary tract,** whether of toxic or bacterial origin. It has the particularly satisfactory result of clearing away septic conditions associated with tuberculosis of the kidneys."

From *The Lancet*, Aug. 23rd, 1913.

"Cystopurin has been spoken of very favourably in the treatment of tuberculosis of the urinary tract. . . . The presence of sodium acetate in the molecule appears to secure a specific effect, whether the urine is ammoniacal, alkaline or neutral. The diuretic action of the compound is an obvious advantage."

Cystopurin diminishes the amount and thickness of the discharge in Gonorrhoea, it relieves the pain and promotes free diuresis, and if used sufficiently early, the disease is localised to the anterior urethra, complications are prevented, and the duration of the attack is shortened.

In all diseases wherein the urine is septic, turbid and evil-smelling, Cystopurin has proved of the greatest clinical value after the failure of other urinary antiseptics.

The action of Cystopurin does not, however, depend upon any assumed liberation of Formic Aldehyde in the urine, but is due to the specific effect of Hexamethylene-tetramine which is hurried to the bladder, before it becomes decomposed, by the diuretic action of the Sodium Acetate.

Dr. Loose *(Deutsch. Med. Woch.*, 1907, No. 2) says: "Cystopurin is a chemical substance able to influence the lymph stream in the areas with which it comes in contact, and is one which cures by a process similar to that seen in artificial hyperæmia."

IN

Iodine Therapy.

Activity of IODÉOL.

In the comparative study of the properties of *IODÉOL*, one is at once struck by the fact that whereas ordinary isotonic solutions of colloidal metals contain *only 0·20 gm. of metal per litre*, *IODÉOL* contains the same quantity *in each cubic centimetre*. One ccm. of *IODÉOL* is therefore *one thousand times as active* as the same quantity of the ordinary solutions of metallic colloids. The indications for the therapeutic employment of a colloid such as *IODÉOL* are therefore numerous.

IODÉOL is specific for ***Pneumococcal Disease; Simple Pneumonia, Infective Pneumonia, Broncho-Pneumonia, Pulmonary Congestion*** both in man and animals. It acts as a diaphylactic, germicide, and lymphagogue, liquefies the exudations, modifies the character of the expectoration, relieves cough and dyspnœa, and brings about defervescence within 48 to 72 hours. Mortality barely reaches 3°/₀.

Drs. HERY, BLANC, PHILOUZE
(Therapeutic Society).
Drs. MIETTE, BRUNET, BOURGEOIS
(Int. Cong. Path., Paris).

Intra-muscular Injections of IODÉOL are painless; they should be administered in the gluteal region at the seat of election, a needle one and a fifth inches long and one thirty-sixth of an inch in diameter being employed.

CAPSULES containing doses of 4 grains of electro-chemical colloidal Iodine perfectly tolerated. Ten times more active than iodides, yet never producing iodism.

LIQUID for EXTERNAL use containing colloidal 50°/₀ Iodine (should never be injected). Used in the same way as tincture of iodine, but ten times more active. Never causes burns or irritation, does not colour the skin, and is absorbed extremely rapidly.

OVULES. Each containing 22 grains colloidal Iodine.
ANTISEPTIC without **IRRITATION.**

IODARGOL

The specific of GONORRHŒA, Acute or Chronic. Painless Injections.

The Treatment of Syphilis.

At the International Congress of Medicine Ehrlich stated that the biochemical action of SALVARSAN on spirochœtes is not direct but indirect, a third factor found in the body fluids being necessary.

This is emphasized by the well-known experiment of LEVADITI: "*If living treponemas be placed in a solution of Arseno-benzol (Ehrlich's 606), they continue to live in it. But if a trace of extract of liver be added to the mixture the treponemas are destroyed.*"

"If 606 has to be taken up and transformed ***by the liver*** in order to become toxic to the treponema, there is no better mode of absorption of the drug than ***by way of the intestine,*** since all the ***veins of the intestines*** join the ***portal vein.*** If this be the case no route could be more indirect and more unsatisfactory for active treatment than one that is not intestinal or not intravenous (i.e., pre-hepatic), since some of the drug must necessarily become fixed everywhere before its passage through the liver has activated it."—Dr. SABOURAUD, *La Clinique* (13/4/13).

As a result of numerous clinical experiments Dr. BAGROV, of Moscow, has arrived at the same conclusions, and extols the ***rectal method*** of administration of 606.

The rectal method of administration of 606 may be recommended to medical men who do not wish to employ intravenous injections. It yields ***excellent results,*** absolutely comparable with those obtained by the intravenous method, and is ***free from all risk.***

In order to render the employment of suppositories containing 606 practicable, it was necessary to find some excipient that does not alter the active principle, even if kept for a long time, and that facilitates its absorption by the intestinal mucous membrane.

This requirement has been realized in our

SUPSALVS

Stable Suppositories,

each of which contains 0·10 grm. (1 gr. 5) of Arseno-benzol (Ehrlich's 606).

Box of 6 "Supsalvs" (Adult)	12/-
Box of 6 "Supsalvs" (Infants)—dose 0·03 grm. (0 gr. 50)	7/6

"SUPSALVS" are delivered with a **MEDICAL PRESCRIPTION ONLY.**

THE LANCET.

LONDON: SATURDAY, APRIL 11, 1914.

Uterine Hæmorrhage.

THE subject of uterine hæmorrhage is one of great interest and importance. We are not acquainted with the exact nature or meaning of menstruation and we are still ignorant to a large extent of the factors which initiate and control it, facts which render any addition to our knowledge of this function a distinct gain. Mr. H. BECKWITH WHITEHOUSE is to be congratulated on having made this problem the subject of his Hunterian Lecture, which was published in full in THE LANCET[1]; he has certainly added something to our knowledge both of the physiology and pathology of hæmorrhage from the uterus. It is only of recent years that the exact relation of menstruation to the changes associated with the phenomenon of rut in the lower animals has been determined, though the researches of HEAPE and others have shown that menstruation may be regarded as analogous to the procestrum of the primates, which reaches its highest stage of development in the human female.

A question which has always excited attention is the cause of the non-coagulability of the menstrual blood. This has been attributed on the one hand to the absence from it of fibrinogen and of fibrin, and on the other hand to its containing an excess of antithrombin. Mr. WHITEHOUSE points out that in a considerable number of women clots actually are passed, but as a general rule the menstrual blood does not clot. He, however, produces evidence to show that the menstrual blood does clot in the uterus when the endometrium is healthy, and attributes its fluid character in the vagina to the fact that in this canal the clot is dissolved by a fibrinolytic enzyme or similar substance which has the power of digesting fibrin and breaking down blood clot. His experiments certainly seem to show that there is a specific fibrinolysin in the fluid portion of the menstrual blood, and that it acts in a quantitive manner, since it will not produce the resolution of an unlimited amount of thrombus. He has further shown that this property is not due to any of the normal constituents of the menstrual blood, such as mucin, calcium salts, lactic or butyric acids. This thrombolysin is believed to be a product of the glands of the body of the uterus, and is poured out by them into the cavity of the uterus, more especially at the time of menstruation. Experiments have shown that both the tissues of the endometrium and the menstrual blood have the property of diminishing the coagulation period of normal blood. This power is attributed to the presence in them of a considerable amount of a substance called thrombokinase. In the normal coagulation of the blood thrombokinase, which is present in varying amount in the tissues, promotes the union of the thrombogen and calcium salts of the blood plasma and produces thrombin, and this in its turn acting upon the fibrinogen converts it into fibrin. Any excess of thrombin is inactivated by a hypothetical body termed antithrombin, and the presence of this body in excess, as we have seen, is one of the reasons assigned for the failure of the menstrual blood to clot. The power of the stroma cells of the endometrium to produce thrombokinase is regarded as a provision of nature to facilitate clotting and to prevent hæmorrhage. The fact that even in well-marked cases of hæmophilia hæmorrhage very rarely occurs during menstruation is regarded as a clinical argument in favour of these views.

What is the machinery which controls normal menstrual hæmorrhage? Mr. WHITEHOUSE suggests that three factors may be concerned, the effect of uterine contractions, the action of a hormone or hormones producing capillary dilatation in utero, and the biochemical function of the endometrium. The experiments of C. J. BOND and some undertaken by the lecturer seem to show that the uterine secretion, in rabbits at any rate, is under the control of the ovaries both in regard to its amount and physiological action, and further suggest that the secretion of the uterus, stimulated and controlled by an ovarian hormone, is partly absorbed and produces the dilatation of the vessels which is characteristic of the late stages of the procestrum. If we accept these views, the presence of clots in menstrual blood may be due to a deficiency of thrombolysin in the uterine secretion, or occur because the amount of blood is too large or its escape too rapid for the thrombolysin to act. That the normal balance between the thrombotic and thrombolytic properties of the endometrium is easily upset is shown by the fact that some 50 per cent. of all women pass clots from time to time. If now, in the light of these observations, we consider the causes of excessive pathological bleeding from the uterus of endometrial origin, obviously it may be due to diminished power of the secretion to produce clotting of the blood or an excessive secretion from the uterine glands producing marked resolution of the clots. A clinical example of the latter would be the excessive hæmorrhage often met with in glandular hypertrophy of the endometrium. The fact that uterine hæmorrhage is not infrequently accompanied by some hypertrophy of the ovaries is well known to all gynæcologists. If this is associated with an increased internal secretion from the ovary and also from the uterine glands, which in its turn is absorbed and produces vaso-dilatation in the uterus, then one method of arresting uterine hæmorrhage would appear to be reducing the ovarian secretion.

---

[1] THE LANCET, March 28th, p. 877, and April 4th, p. 951.

The functional hæmorrhage of puberty Mr. WHITEHOUSE seeks to explain by excessive action of the hormones with maldevelopment of the endometrium and therefore delayed coagulation, while the functional hæmorrhage of the menopause is said to be due to a disturbance of the normal balance in that the ovarian secretion is still producing its vaso-dilator effects at a time when the endometrium has undergone atrophy and the musculature of the uterus fibrosis.

In considering the incidence of excessive uterine hæmorrhage in relation to organic disease of the internal sexual organs attention is called to the fact that uterine displacements cannot be regarded as a cause of excessive bleeding. Of late years the condition termed fibrosis of the uterus and chronic metritis has taken a prominent place among the factors supposed to produce severe uterine bleeding. The work which has recently been published upon this subject by BRIGGS and HENDRY would seem to prove that it is extremely doubtful if there is any causal relationship at all between the condition of so-called fibrosis uteri and severe hæmorrhage. We need not follow the lecturer in his analysis of the relation between various pelvic diseases and uterine hæmorrhage, since the conclusions he comes to are identical in the main with those of most other observers. At the same time we think that until there is more certain evidence of the exact relationship of the ovaries to hæmorrhage from the uterus his recommendation of partial oöphorectomy when bleeding, the result of excessive thrombolysis associated with hypertrophy of the endometrium, is not relieved by curettage requires very careful consideration. There is much in the lecture to interest everyone, and if the views put forward are confirmed by other observers they will do much towards placing our treatment of these conditions upon a more certain and scientific basis.

◆

A New History of Medicine.[1]

"WHETHER I am likely to perform a task worth the trouble in writing a history of the Roman people from the very beginnings of the city I do not know, nor if I did would I venture to say. ...... The subject is one of unbounded labour, for it goes back more than 700 years, and having started from very small beginnings has grown to such magnitude that it begins to weary from its very greatness." In these words one of the greatest of historians began his chronicle of the deeds of the Roman people, and the words may well serve as a motto for any historian of to-day. The doubts expressed by LIVY in his opening sentence have not been endorsed by the countless readers of his history, but everyone who writes history to-day, and who aims at making his record comprehensive and authoritative, whether the subject be world-wide, national, or periodic, must feel a similar doubt. The historian of medicine is placed in as anxious a position as that to which LIVY calls attention. The first beginnings of medicine seem trivial and even childish, and the subject, instead of going back only 700 years, reaches back for something like 3000 years, or even further. The history of nations and peoples deals with the relations of one towards another, with wide questions of economics, politics, tribal migrations, the arts, the sciences, wars, and incidentally with epidemics, such as the Black Death. But the history of medicine looked at from one point of view is primarily only concerned with the two great problems affecting humanity—namely, birth and death—although these two connote innumerable others. For it is nowadays almost a commonplace to observe that medicine has to deal not with bodies alone, but with men and women whose psychical and physical sides are inextricably bound up one with the other. As PLATO said long ago: "Just as you ought not to attempt to cure the eyes without the head, or the head without the eyes, so neither ought you to attempt to cure the body without the soul."

The history of medicine is indeed to a great extent the history of human thought, and involves the consideration of primitive religion and the dawn of natural philosophy, the problems of agriculture and the discovery of plants good for food and the reverse; and institution of efforts to avert epidemics. When we add to these and other allied topics the great and mainly unsolved problem of how the human body works, of its defensive mechanism against disease organisms, of the life history of these organisms themselves, of the influence on the body of climate, environment, and employment, we may well say that "the subject from very small beginnings has grown to such magnitude that it begins to weary from its very greatness," and it is becoming obvious that the history of medicine will have soon to be treated after the fashion of the Cambridge Histories—that is to say, in periods by specialists. Nevertheless, a handbook dealing with the matter as a whole is still a necessity for the commencement of the study, and such a handbook now lies before us in the shape of an admirable "Introduction to the History of Medicine," by Dr. FIELDING H. GARRISON, the principal assistant librarian of the Surgeon-General's Office, Washington, D.C. A careful study of Dr. GARRISON'S book warrants us in saying that it is the best general history of medicine at present to be found in the English tongue, and we say this in no disparagement of Dr. WITHINGTON'S admirable "History of Medicine from the Earliest Times," for the latter appeared as long ago as 1894, and did not pretend to deal with modern medicine after the time of BICHAT.

Dr. GARRISON commences with a survey of Egyptian, Sumerian, and Oriental medicine; then he passes to Greek medicine, divided into three stages—the pre-Hippocratic, the classic from 460 to 146 B.C., and the Græco-Roman period

[1] An Introduction to the History of Medicine, with Medical Chronology, Bibliographic Data, and Test Questions. By Fielding H. Garrison, A.B., M.D., Principal Assistant Librarian, Surgeon-General's Office, Washington, D.C. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 763. *Price 25s. net.*

(146 B.C. to 476 A.D.); then the Byzantine to 732 A.D.; next come the Mohammedan and Jewish periods to 1096 A.D., the mediæval period to 1438 A.D., and the Renaissance and Reformation period to 1600 A.D. The chapters which follow deal with the seventeenth, eighteenth, nineteenth, and twentieth centuries as periods in themselves. One valuable, and we think new, feature of Dr. GARRISON's book is the sketch at the end of each period of the cultural and social aspects of medicine during that period; there are in addition two most valuable appendices dealing with medical chronology and medical bibliography respectively. The work is crammed with dates and bibliographical references, and the latter we are glad to see are very fully given, a point which is frequently overlooked. But Dr. GARRISON being a librarian is naturally only too well acquainted with the slovenly manner in which references are often given, and has spared no pains to make his own accurate and easy to find. In a work of this size, which deals with so long a period and with so many dates, it is inevitable that there should be slips. Despite those which we have observed we have no hesitation in saying that Dr. GARRISON has given to the medical profession, and especially to those members of it who wish to study the history of their craft, a most valuable and informing work, and we have nothing but congratulations to offer him on the way in which he has accomplished the task he has set himself.

Annotations.

"Ne quid nimis."

THEOLOGY FOR MEDICAL MEN.

A FEW centuries ago the principal lights of the medical profession were clerics. With the recent growth of psychological science, and especially with its excursus into the fields of therapy, has grown up a rather voluminous literature from the theological side to re-establish the claims of religious belief and practice as at least a very powerful auxiliary in the healing certainly of the mind, and to a great extent of the body also. But a further indication of the *rapprochement* between the two professions of theology and medicine, which in the latter half of the nineteenth century, and even further back, were becoming more and more estranged, is to be found in the recent appearance of two distinctly theological works from the pens of medical men. The first bears the somewhat cryptic title, "The Interregnum."[1] It consists of 12 essays on religious doubt. By the interregnum the author explains that he means that stage in a man's mental development when the old beliefs and sanctions of childhood are lost and he has not yet had time to form new views of his own. This period is characterised by diffidence, for, as the author explains in the introduction, the unsettled one finds experts disagreeing and feels himself incompetent to decide, and is naturally chary of allowing himself to be persuaded by any elaborate argument, feeling that there may be another side of the argument which he has not yet heard. The object of the author is first to show that it is a natural, right, reasonable, and desirable thing for one who would follow the good to associate sympathetically with Christians as a Christian during the interregnum, even when the balance of evidence may seem to him against Christianity; and secondly, not to prove the truth of Christianity, but to show that the case has not been finally closed against it by any of the rival systems in vogue. How far the author is successful in attaining either of his objects obviously must be settled by each individual reader for himself; suffice it to say that the argument is clearly presented and shows it to be the work of one who has made theology a systematic study, and who has from his medical training an adequate knowledge of the tangential points of both medical and theological science. The other book, "Forgiveness and Suffering,"[2] is a careful consideration of the current interpretations of the Christian doctrine of the Atonement and the problem caused by the presence of pain and evil in a world asserted to be created and controlled by a beneficent yet omnipotent and omniscient Being. In this case also the author, Dr. Douglas White, in virtue of his medical training, is apt to detect where the shoe of Christian dogma pinches the foot of scientific data. It would be out of place in THE LANCET to discuss the theology presented in either of these books. We can, however, conscientiously applaud such obviously sincere attempts on the part of excellently equipped members of the medical profession to extend a hand to earnest doubters struggling in the slough of despond. To those who have finally adopted a mechanistic conception of life, and indeed to all but theists, the books make no pretence of appealing.

EMPIRICAL REMEDIES.

WE publish this week an article on the therapeutic value of the potato, recognising that it is a contribution which differs in some ways from those generally published in THE LANCET. The personal experience of one man with a new therapeutic measure, unless reinforced by scientific reasoning, requires, we consider, more support than the statement that it has succeeded in a certain number of cases. Where the investigator is not a qualified medical man there can be no doubt that no account of a new treatment should be published until it has been fully tested by medical men; and where the suggested treatment is obviously at variance with known physiological or accepted medical doctrine the medical profession is right not to waste time in experimenting. This attitude is, of course, called narrow-minded or short-sighted by the charlatan and by a good number of people who ought to know better, but it is one from which we could never depart in the case of unqualified people. The idea of the treatment may be good, but it must be vouched for by trained intelligence, or a delay most inimical to the interests of the patient might be incurred by valueless trials. But where a medical man invites medical coöperation by asserting that over a considerable period of time he has tried particular therapeutic measures in particular pathological conditions, and has obtained successes to which he wishes to draw the attention of his brother practitioners, the matter is different. Hence the appearance in our columns of Mr. Howard's plea for potato juice in the form of a dressing and liniment in various common and painful conditions. The circumstances in which he recommends the drug are, it will be seen, not those where any serious harm could result to the patient if a certain amount of time in the early stages of the condition were employed in experiment, while a year ago reference was made in these columns to the statements concerning the anodyne and sedative properties of the potato. It will be seen, also, that many of the cases which he quotes are of exactly the kind where the symptoms spontaneously abate, making it difficult for the observer to see how much is due to the remedy and how much is due to nature.

RECURRENCE OF DUODENAL ULCER AFTER OPERATION.

IN the *Boston Medical and Surgical Journal* of Jan. 29th Dr. William J. Mayo has published an important paper on recurrence of ulcer of the duodenum after operation. Gastro-jejunostomy was the method of choice in the majority of his cases. The greater the obstruction, within limits, the better were the results. The converse also held true: cases with slight or no obstruction gave the highest number of failures. Dr. Mayo divides the failures into two groups. In the first the operation does not relieve the stomach of its acid irritating secretions, and the ulcer is inadequately protected during the healing period. This occurs most frequently in cases of no or slight obstruction. The pylorus is open, and much of the food passes through it instead of through the gastro-jejunostomy. In such cases attempts have been made to close the pylorus by infolding with buried silk sutures, but the general experience is that permanent blockage is not produced, and the sutures are eventually passed into the lumen of the stomach with restoration of the channel. For some time a method devised in Germany has been practised at the Mayo clinic. A strip is cut from the gastro-hepatic or gastro-colic omentum, left attached at one end, and drawn twice about the stomach just above the pylorus or, if the ulcer is sufficiently far from the pylorus, the strip is passed about the duodenum above the ulcer. The site of blocking is diminished in size by the application of several interrupted sutures of fine silk to take the strain during healing. As far as can be ascertained the blockage has remained permanent since this procedure has been followed, but sufficient time has not elapsed to show its exact value. However, it is certain that living tissue drawn about the pylorus is more permanent than devices in which foreign bodies, such as thread, are used. In one case a patient was re-operated on after a year, and a strip of living tissue was found in place and covered with adhesions and the pylorus securely blocked. Another method, adopted by von Eiselsberg, is to divide the pyloric end of the stomach and close both ends, but it has a definite, though small, mortality. In duodenal ulcer without obstruction, when the conditions are favourable, Dr. Mayo excises the ulcer. In his early cases he excised the ulcer alone, but a considerable number relapsed within a year. He therefore found some drainage operation, either gastro-jejunostomy or a plastic operation on the pylorus, necessary. Following this, if the pyloric obstruction is slight the ulcer is infolded, as suggested by Sir Berkeley Moynihan, and the pylorus is blocked by living tissue. If the obstruction is marked only gastro-jejunostomy is necessary, though infolding of the ulcer is advisable. When there is a history of hæmorrhages the regional blood-vessels are caught by sutures and tied. In the second group of failures recurrence of the ulcer was only apparent. The trouble was due to improper suturing of the gastro-jejunostomy, at the site of which a new ulcer forms in consequence of heavy silk or linen sutures hanging in the suture line. The length of time these sutures will hang is remarkable; in one case it was 22 months. Eight cases of this kind were re-operated on in the Mayo clinic, in five of which the original operation had been done there. In two there were intercommunicating fistulæ between the stomach, jejunum, and transverse colon. In both of these cases there was fæculent material in the stomach. The finding of colon contents in the stomach after a gastro-jejunostomy is an indication of perforation of a gastro-jejunal ulcer into the transverse colon. In five of the cases heavy strands of silk or linen were hanging in the wound. In two of the cases the condition of the tissues was such that after removal of the suture it was thought wise to cut away the gastro-jejunostomy, completely restoring the wall of the stomach and jejunum by suture and then doing a plastic operation on the pylorus. This procedure proved so difficult that in later cases the gastro-jejunostomy was reopened in the suture line and the suture extracted. The opening was then enlarged by a plastic operation, using interrupted sutures. Such experiences teach that very fine silk should be used for gastro-jejunostomy, that the bite should be as near the margin of the incision as possible, and that, if it is necessary to reinforce a weak suture line, interrupted fine silk sutures are advisable or such sutures should be used for part or the whole of the outer row. It has been Dr. Mayo's practice for a long time to use catgut for the inner row, but it is not this which gives trouble.

SPLENECTOMY AND INCREASED RESISTANCE TO THE TUBERCLE BACILLUS.

OBSERVATIONS directed to show evidence of any power of aiding the body defences against organisms must receive careful consideration. In relation to the tubercle bacillus especially are they of value. Some striking experiments upon the results following removal of the spleen in mice and rats, which appear to demonstrate an increase in the power of resistance to the tubercle bacillus, have been recorded by Lewis (Paul A.) and Margot (A. G.) in the *Journal of Experimental Medicine* (1914, Vol. XIX., p. 187). Into the peritoneal cavity in 21 albino mice was injected a culture of bovine tubercle bacilli; the quantity varied from 1 to 5 mgr. in different animals. Within a time varying from a few hours to a few days all these animals died, and post-mortem examination showed extensive infection of many organs. A similar proceeding applied in 13 mice of similar weight, from which, however, the spleen had been removed, but which had fully recovered from the effects of the operation, showed that a marked lessening of the effects of the inoculations had occurred. Four of the animals were still living at the time of writing, and the rest survived a longer time than did the non-splenectomised animals. Further, the range of infection was more limited in the body. Similar results were gained in rats. In order to test the strength of the possible *objection* that the mechanical effect of the removed spleen altered in some way the character of the peritoneal inoculation, a second series of *animals* was inoculated into the pleural cavity. Ten controls all died; of the ten splenectomised animals, two survived, and the rest, again, lived for a much longer time. In this series, too, the range of infection was limited. Similar experiments upon guinea-pigs and dogs were not successful, and the same results were not gained. The writers cite these observations as being some of the few striking instances of the power of increasing resistance to organisms. Such experiments should stimulate others upon similar lines and suggest a line of research of considerable practical value.

A NEW ROMAN OCULIST'S SEAL.

A LONGER interval has elapsed than has occurred for many years since the discovery of a Roman oculist's seal. A new seal is now reported as having been found in France, at Beaumont, in the Puy-de-Dôme. It bears an inscription in eight lines, half of which are the *quadruple* repetition of the owner's name, a new one in the category of Roman oculists. The text runs as follows: "Aulus Uritius Hermodorus: Melinum Opobalsamum ad Aspritudines. Diasmyrnes lenementum Thurinum ad (Suppurationes). Crocodes ad Caligines." The name Hermodorus, or Hermodoros, suggests Greek nationality, genuine or assumed, for the oculist, and it is interesting to note that three of the collyria are merely Latin renderings of Greek titles, opobalsamum being ὀποβάλσαμον, diasmyrnes διασμύρνης, and *crocodes* κροκώδης. Opobalsamum, sometimes on these signets written opobalsamatum and diaopobalsamum, was balm; it is enumerated as a remedy upon these seals, and not heretofore as a cure for *aspritudines* or the palpebral granulations of ophthalmia. Here the word is qualified by the word melinum, which has appeared previously upon several of these signets and has given rise to some discussion. One explanation is that it refers to the yellow colour of the remedy. In fact, Galen says distinctly that the "emplastra melina" were *thus* named because of their "colour," which may have been *produced* by oxide of copper. Sir James Y. Simpson was the first to discuss the *precise meaning*, or meanings, of melinum, when noting in his "Archæological Essays," 1872, the discovery of an oculist's seal at Bath. This bore an inscription reading "Chrysomælinum ad claritatem," meaning *obviously* that the collyrium was of a golden yellow colour. *In* another seal the *balm* is qualified as "cloron" (χλωρός, green). Subsequently *another* seal discovered at Cirencester again brought the word into prominence; it read "Melinum ad omnem dolorem." Sir James Simpson cited several instances in which Galen uses the term "melinum" as indicating the colour of collyria, and proceeded to make up a specimen collyrium, using the ingredients prescribed by Galen *to* produce what he had termed "collyrium melinum delicatum." The result was a composition of yellow colour. The same effect would also be arrived at by the collyria Galen terms "*melines*," which have saffron as an ingredient.[1] There is, however, good reason for thinking that in some cases the name "melinum" had quite a different derivation and meaning. Pliny says when writing of alum: "The best is that which is called melinum from the isle of Melos. It represses the granulations in the eyes (oculorum scabritias extenuat)." In another passage he states that the Melos alum is the most efficacious. *It* is true that up to the present no oculist seal yet recovered has certified melinum as a special remedy for scabrities, save the Cirencester seal with its inclusive recommendation "*ad* omnem dolorem." It is certain that Melos alum in classical times had a geographical title, that of melinum, just as we speak of gum arabic *or cognac*. *Moreover*, the connexion of the Melian melinum with collyria viridea is distinctly confirmed by Dioscorides, who says of melinum, "Emplastris viridibus efficacitur inseritur." This agrees with both Andromachus and Galen, the first of whom gives 14 and the second 11 emplastra melina. A third possible derivation of melinum is μήλινος, "pertaining to quinces." Pliny refers to melinum (oleum) quince oil, and melinum (unguentum) quince ointment. Thurinum (sometimes Turinum) is derived from thus (sometimes tus), θύος, incense. This term was used occasionally for dialibanum, the Latin equivalent of διαλιβάνων. Many classic writers affirm its efficacy for ocular diseases. Floridus Macer relates its virtues in the following panegyric:—

> "Thus calidum siccumque gradu dixere secundo,
> Lumina clarificat, lacrymo si solvitur ovi
> Contritum vel femineo cum lacte tepenti."

Many oculist seals speak of women's milk as entering into their collyria. The word *following* Thurinum is effaced, but was probably "ad suppurationes." A seal whereupon Turinum provides a cure for suppurationes is that of an oculist, M. J. Satyros, which is in the British Museum. The final sentence, "crocodes ad caligines," refers to saffron, a medicament mentioned almost as frequently as myrrh upon these relics, and held to possess the property of improving obscure vision. A special kind of crocodes named "crocodes of Mars" was a bicarbonate of iron. Some of the crocodes specified by oculists on the seals are specified as crocodes Paccianum. The title was derived from the name of the famous Augustan physician, Paccius Antiochus. Curious details as to his attainments and career are to be found in Scribonius Largus (De Compo. Med., c. xiii.). So great was his reputation that both medical men (including Galen) and quacks applied the term paccianum to their various special preparations. Diasmyrnes, or myrrh, is the most favourite remedy mentioned upon relics of this kind. Galen and Scribonius Largus give many collyria containing myrrh. The best specimens came from Arabia and Syria, probably, as the name suggests, from Smyrna. It was an article of commerce, the price of which could be artificially raised by cornering it, and was therefore included in Diocletian's great edict, "De pretiis rerum venalium," which fixed a maximum price for articles of *public necessity*. The occurrence of this ingredient upon the oculist stamps was fully treated of in THE LANCET of August 10th, 1907. Lenementum (or lenimentum) implied a soothing remedy. Ancient medical authors applied the term "lene" to many remedies. Aetius says: "Leniora medicamenta semper sunt inflammatis partibus accomodatiora; verum debiliora quam ut, depulsa inflammatione, ad perfectam sanitatem perducere queant."

---

[1] Galen specially mentions three melina—M. Atarachum, M. Lucil, and M. Delicatum.

THE CULTIVATION OF MALARIAL PLASMODIA IN VITRO.

All attempts to obtain cultures of malarial parasites outside the living body had failed up to 1911, when Dr. Charles C. Bass, of the Tulane School of Tropical Medicine, New Orleans, succeeded in cultivating plasmodium vivax, P. falciparum, and P. malariæ *in vitro*. His technique was described at the time, but has been improved and modified since then as a result of further researches made, in conjunction with Dr. F. M. Johns, in the Panama Canal Zone during 1912. Dr. Bass in 1913 summarised the present state of our knowledge respecting the cultivation of malarial parasites in a paper which he read before a meeting of the American Society of Tropical Medicine at Washington, D.C., and which has recently been published in the current number of the *American Journal of Tropical Diseases and Preventive Medicine* (Vol. I., No. 8). In this communication details of Dr. Bass's technique are set out, and it is interesting to note that his work has been repeated and confirmed by various experts in England and Germany as well as in America. By using this technique, or some slight modification of it, the cultivation *in vitro* of two other red blood-cell parasites—namely, piroplasma canis and P. bigeminum—has been found possible. The malarial plasmodia have only been successfully cultivated in the presence of red blood cells. In these cultures the asexual parasites grow, segment, and form rosettes which burst and give rise to merozoites, many of which enter new red blood cells in precisely the same way as they do in the living human body. From his observations of the parasites *in vitro* Dr. Bass believes that *in vivo* the plasmodia can pass from cell to cell solely when a cell is in direct contact with another one containing a segmenting parasite, and then only when the opening for the exit of the merozoites occurs opposite to the cell to be infected. It appears that the substance of malarial plasmodia differs in consistency from that of the red blood cells, and in consequence the former cannot pass through the smallest capillaries as can the more yielding fluid-like red blood cells. As a result of this unyielding consistency malarial parasites, after they attain sufficient size, lodge in the capillaries of the body, particularly in those parts where the blood current is weakest and where slight obstruction is produced by the protrusion inwards of nuclei of endothelial cells. When this lodgment occurs other red blood cells are forced against them, and if the opening in the infected cell occurs in a favourable position one or more merozoites pass directly into the other cell. If, however, the opening is on the side of the infected cell in the direction of the current the merozoites are poured out free into the blood stream and are killed at once. When the segmented parasite has become broken up sufficiently it can pass on through the capillary into the circulation, where the remaining merozoites are almost instantly destroyed. The débris and pigment are "phagocytised" by the mononuclear cells of the blood and the endothelial cells of the vessels, and finally are either destroyed or stored in the spleen or other tissues of the body. A very heavy infection may result in plugging sufficient of the brain capillaries to produce "cerebral malaria" or coma similar to that occurring in the case described by Captain A. G. Tresidder, I.M.S., in The Lancet of March 28th (p. 891). It has been suggested that quinine has no direct destructive effect on malarial plasmodia, the action of the drug being, perhaps, to render the red blood cell protecting the parasite more permeable to the all-sufficient influence of the serum. If this be true it appears to Dr. Bass that quinine would only affect the parasites in the circulation and not those lodged in the capillaries; these would not be reached by the quinine until they had segmented. The effect of quinine is defeated by influences such as diet and exertion, which increase the dextrose content of the blood, whereby the permeability of the red blood cells seems to be decreased. The size of the capillaries and the amount of blood pressure have an important influence upon the stage at which malarial parasites recede into the peripheral circulation. It is possible, in Dr. Bass's opinion, that these conditions may after all be material factors in the production of cerebral blocking and its consequences in malaria.

A SALIVARY CENTRE IN THE MEDULLA.

It was thought at one time that the secretion of saliva was a purely reflex affair. This view was at a later date disproved, and it was shown that whilst the mechanism was to some extent a reflex act, yet its processes were intimately controlled by central influences; but even then the range of this central control and its extraordinary powers of influencing not only the quantity but also the quality of the saliva were not realised until the work of Pawlow was published. With these observations in view the probability now arose that there might exist some definite anatomical basis for this central control in the form of a special collection of cells in the bulb constituting something in the nature of a nucleus, and in the dog such a collection of cells fulfilling this controlling action was discovered in the bulb. The final possibility to be expected was that in man an analogous structure might be found, though the unusual character of lesion which it was anticipated would induce loss of salivary control—namely, one particular to a relatively small area in the bulb—offered practical difficulties. A case, however, has been reported by Feiling in *Brain* (1913, XXXVI., 255), the pathological examination of which appears strongly to suggest that something in the nature of a salivary nucleus does exist in man. The patient, a man, had a fractured base, and died 71 days afterwards. There was found, post mortem, local injury of the trunks of the vagus, glosso-pharyngeal, spinal accessory, and hypoglossal nerves near their exit from the skull. The paralysis during life involved the left side of the tongue, left sternomastoid and upper part of the trapezius, loss of taste at the back of the tongue left side, left palate, aphonic speech, left vocal cord immobile, and absolute loss of the power of swallowing. There was continuous dribbling of saliva. In the bulb, on microscopical examination, there was found degeneration of the cells of origin in the above nerves. In addition, however, there were scattered degenerated cells in the grey matter of the upper part of the medulla, just dorsal to the inferior olive, extending from the level of entry of the cochlear fibres below to the termination of the inferior olive above. Though these cells cannot be said to constitute a definite nucleus, it is suggested that they are specially concerned in salivation, and that they represent the cells of origin to secretory fibres which pass out with the glossopharyngeal, and which later, by means of the tympanic branch, become distributed to the parotid.

SUDDEN DEATH FOLLOWING PYELOGRAPHY.

THE practice of taking skiagrams of the pelvis of the kidney and the ureter after the injection into them of some fluid opaque to the X rays is becoming so common that it is of importance to note any cases in which harmful results have followed or have appeared to follow this method of diagnosis. Dr. E. O. Smith, of Cincinnati, Ohio, has recorded a case in the Transactions of the American Urological Association, 1913, in which sudden death followed closely on pyelography. The patient was a woman aged 64 years; she was poorly nourished, but she was able to walk into the cystoscopic room without assistance. The bladder was normal, and both ureters were catheterised without difficulty, and some urine was collected from each kidney, and in neither specimen was there pus or blood. It was decided to take a skiagram of the pelvis of the right kidney two days later, and for this purpose 20 cubic centimetres of a 10 per cent. solution of collargol were injected through a ureteral catheter by means of a small hand syringe. But little force was used and the injection was stopped as soon as the patient complained of pain. A skiagram was then taken. Only some six or eight minutes elapsed between the introduction of the cystoscope and its removal, and five minutes later the patient was dead. At the necropsy several serious lesions were found to be present. There were extensive pleuritic adhesions, and tuberculous nodules in each lung, and there was old disease of the mitral valves. There was much pus with many gall-stones in the gall-bladder, and an abscess beneath the liver communicated with the gall-bladder. Both kidneys showed an acute interstitial nephritis superimposed on a chronic nephritis; and the right kidney contained collargol in the uriniferous tubules and between the tubules. It is clear from the necropsy that this patient had several other lesions which must have had much influence in determining the fatal issue, but it is also clear that the collargol had damaged the kidney. It is generally agreed that hydrostatic pressure is the best means of injecting collargol into a ureter.

A NEW PHYSIOLOGICAL HÆMOSTATIC.

ATTENTION is drawn in a recent number of *Il Morgagni*[1] to the use of the fibrin ferment of the blood as a valuable hæmostatic. This substance is to be found in all the cells of the organism and extracts of all fresh organs contain it. As prepared by Zanoni it exists as a fine powder, of a colour varying from light to dark yellow, slightly unctuous to the touch, and with an odour like that of goose fat. It is slightly hygroscopic and but little changed by light and air, sparingly soluble in water and chloroform, and less still in 95 per cent. alcohol. Aqueous solutions are not limpid, are markedly opalescent, and leave an insoluble residue; they cannot be filtered since most of the ferment remains on the filter. They must therefore be used as they are. This substance, which Zanoni has named "coaguline," reduces the time required for the formation of blood clot from 15 minutes to 1 minute. In other words, the blood coagulates almost immediately in the presence of coaguline, and this power is retained for at least five to six months when it is preserved in the form of powder; after this it gradually diminishes. Certain preparations, however, have remained strongly active even after a year or more. The coagulating power of coaguline resists heat to a certain extent, for even after heating the powder or solution to 95° C. in a water bath its activity is still manifest, although somewhat weakened. This necessitates the time and temperature for sterilisation being reduced to a minimum. Coaguline promises to be of use in checking superficial hæmorrhages and in bleeding from viscera, especially the liver, from the nose, mouth, uterus, and from hæmorrhoids. To ensure a full hæmostatic action it is not enough to apply the powder or solution to the bleeding surface since the blood would wash it away before it had time to complete its coagulating action; it must be kept *in situ* for a short time with a pledget of cotton or gauze and with slight pressure. The solution can be injected into cavities and operation wounds, but for hypodermic use a solution having an insoluble sediment is not suitable. To obviate this the author found that by incorporating the coaguline with sugar an opalescent solution could be obtained with water which could be sterilised by heating.

PROVISION OF INSTITUTIONS FOR THE TREATMENT OF TUBERCULOSIS.

WE have received from the Local Government Board a copy of a memorandum on provision of new residential institutions for the treatment of pulmonary tuberculosis which has been sent to the councils of counties and county boroughs. The memorandum has been prepared with the view of affording local authorities and others further assistance in the provision of special residential institutions in connexion with permanent schemes for the treatment of pulmonary tuberculosis. Attention has wisely been drawn to the fact that the planning of the institution will depend on the stage of disease of the tuberculous patients proposed to be admitted to it. A classification of cases of pulmonary tuberculosis is set out arranged from the standpoint of accommodation in residential institutions. Group A contains those cases in which permanent improvement or recovery may usually be anticipated; Group B, cases in which only temporary, though possibly prolonged, improvement may be anticipated; Group C, advanced cases requiring continuous medical care and nursing; Group D, cases requiring special observation: (1) patients admitted for the purpose of diagnosis; (2) patients needing to be watched before the best form of continued treatment can be determined. This is a good practical classification, and we also endorse the further statement that the term "sanatorium" should be used to indicate an institution mainly devoted to the reception of patients in Group A, the term "hospital" to indicate an institution provided for the reception of patients in Groups B, C, and D, and the term "combined institution" to indicate an institution devoted to the reception of patients in all four groups. If admissions to a sanatorium were strictly confined to patients suffering from pulmonary tuberculosis who are afebrile and able to take a certain amount of exercise, the results obtained would be more satisfactory than is at present the case. The types of buildings which are suggested are on the whole satifactory, but we do not like the plan of placing the consulting-room, laboratory, and dispensary in the same building and on the opposite side of a passage to the kitchen and scullery. The memorandum bears the names of Dr. A. Newsholme, medical officer to the Board, and Mr. Brook Kitchin, architect to the Board. Much care and thought have evidently been given to its preparation.

---

[1] Il Morgagni, Anno lvi., No. 17, March 22nd, 1914, Milano.

HOSPITAL MORBIDITY STATISTICS.

IN a leading article on Jan. 31st of this year we referred to the subject of hospital statistics, and pointed out some of the difficulties which would be encountered in rendering them suitable for satisfactory collection and study. We also mentioned that in an article in the *Hospital* a proposal had been made that a bureau might be formed under the supervision of a statistical committee nominated by the authorities of the different hospitals concerned. In connexion with this subject we have received a pamphlet on hospital morbidity statistics by Dr. C. F. Bolduan, assistant to the general medical officer of the Department of Health of the city of New York. He points out that in the United States practically the only vital statistics available for the guidance of public health administrators are those collected and published by the various boards of health—namely, statistics concerning births, deaths, and marriages; but no general data are available concerning the occurrence and distribution of non-fatal cases of disease, except for a comparatively small group of diseases. He has therefore devised a system of "book-keeping" for hospitals whereby various hospitals might be induced to record all their cases according to a uniform nomenclature. The basis of this system is a "discharge certificate," giving, in addition to the patient's name, age, occupation, date of discharge, and admission to the hospital, and so on, the diagnosis arrived at, and any complications which arise. The certificate is well drawn out, and would afford information useful for statistical purposes. A central bureau would have to be established, and all the certificates examined by a trained medical registrar, who would have them arranged according to a standard nomenclature. Dr. Bolduan gives a number of specimen tables to show the utility of such certificates. He also describes the plan adopted for compiling mortality statistics in New York city. His description is rather difficult to follow, but it is carried out by a "tabulating machine." If a system of this kind could be adopted by a collaboration of the hospitals the results would probably be valuable, but it would involve considerable expense, and the appointment of trained men as statisticians would be necessary.

THE PROTECTIVE ACTION OF THE ADRENAL GLANDS.

THE internal secretion of the adrenal glands possesses many powerful properties. They appear to be part and parcel of the sympathetic nervous controlling system; they influence the quality of tone to a marked degree; they are able to induce metabolic changes, as shown by ability to increase the sugar metabolism and to lower the sugar tolerance of the individual. They are, finally, intimately related to the other glands of internal secretion. Now all these qualities, by their very variety and also by the fact that there is never demanded, from one or other or all, isolated and outstanding activity, had for long eluded detection; their massed effect is pooled, as it were, over many general activities, but this very condition suggests that they are concerned in the regulation of general states of the body. Such general states may be well represented by the responses to emotion, especially fear and hate, and as these conditions have their original causes in the elemental need for the preservation of the individual, it would be expected that protective mechanisms, if present, would, under these circumstances, be most powerfully evoked. It would be anticipated, too, that the adrenals would take some part, though the obscurity of their objective effects has prevented our realising exactly what they do. W. B. Cannon, in the *American Journal of Physiology* (1914, XXXIII., 356), reviews the evidence, which goes to support strongly the view already anticipated, that the adrenal secretion can be brought into rapid and valuable action upon lines calculated to strengthen the individual against possible harm, and is similarly brought into play with the major forms of emotion. Its action consists of a shifting of the blood from the visceral parts to the skeletal; an enhanced force of the heart beat; an immobilisation of the viscera; and, in particular, an increase of sugar-supply to those structures most needing it. The shifting of the blood favours the fuller action of the skeletal elements upon which repulse of injury depends; this is gained at the temporary sacrifice of the viscera, which are immobilised; the more powerful cardiac action is effected by the peculiar action of the adrenal secretion upon the coronary arteries, for these are the only vessels which dilate instead of contract with the action of adrenal. Lastly, the increased ability of the tissues to metabolise sugar increases their power, and in the skeletal tissues this is, again, just what is wanted. The whole gamut of changes afford the spectacle of a most intimate and closely organised arrangement for the rapid focusing of added power to those structures most valuable for the immediate end in view—namely, the protection of the individual.

MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

FOUR years ago the Council of the Royal College of Surgeons of England sanctioned a scheme which is likely to improve the utility of the museum to medical men. The pathological collection—the largest of its kind in the world—has always been divided into two sections, one illustrating the general principles underlying the processes of healing and of disease, the other illustrating the injuries and diseases of the individual systems or regions of the body. In the scheme sanctioned by the Council the section of general pathology has been greatly extended, and now occupies special cases which fill the floor space of one of the chief rooms of the museum. The great task of reorganising this department of the museum has been carried out by the pathological curator, Mr. S. G. Shattock, assisted by Mr. Cecil Beadles. The scheme is now far enough advanced to give visitors to the museum an opportunity of observing the masterly way in which it is being carried out. The sections illustrating the various forms of tumour formation—benign and malignant—are particularly instructive and fully representative of our present standard of knowledge. In the forthcoming series of museum demonstrations, which commence in the theatre of the College on Friday, April 17th, at 5 o'clock, Mr. Shattock will give an account of the sections of this collection which exemplify tumours arising in connexion with bone, the various forms of papillomata and adenomata, and the many varieties of sarcomata. The dates and subjects of these demonstrations will appear in our Diary of the Week. They are open to all students of medicine and medical men. Professor Arthur Keith, who shares the responsibility of these museum demonstrations with Mr. Shattock, has selected the following subjects: Difficulties in the diagnosis of sex, the normal and pathological anatomy of the colon, and adhesions, bands, and mesenteries of the peritoneum.

INTRA-ABDOMINAL MALIGNANT DISEASE.

MALIGNANT disease in the abdomen is one of the commoner causes of the death of middle-aged and old people, perhaps, too, a cause operating with increasing frequency. Yet, as every medical practitioner knows, it is as a rule extremely hard to diagnose in its early stages. In so many cases it is latent, in so many others it simulates some other disorder, that it but rarely comes under observation in time for effective surgical interference, for at the present time the only hope of cure lies in operation. Professor R. Schmidt, of Innsbruck, has written a lengthy essay[1] upon the subject, dividing it into three parts. The first part gives a general account of the methods of examining patients suspected of having malignant growths within the abdomen. He has been accustomed to lay some weight on the presence or absence of Ehrlich's diazo-reaction here. This reaction is almost always positive and well marked in peritoneal tuberculosis, enteric fever, and streptococcal parametritis; it is sometimes positive and often not well marked in various forms of tuberculosis and in cholangitis, and also in malignant disease complicated by secondary infection with B. coli or streptococci. No diazo-reaction is found in the urine of patients with cirrhosis of the liver, myeloid leukæmia, cardiac or hepatic ascites, gastro-enteritis, or gastro-intestinal ulceration. The second part, occupying 100 pages, deals with the various special forms of malignant disease under discussion and the special means by which they may be diagnosed in each case; cancer and sarcoma of the stomach, intestine, liver, gall-bladder, pancreas, and kidney are those chiefly considered. The third part, just half the volume, is filled with numerous illustrative case histories, often completed by the records of obductions. The book is full of valuable matter, prolix, often calling out for condensation. It forms rather heavy going for the casual reader, but is a mine of information for anyone seeking instruction on specific points that fall within its compass. The translator has adhered too closely to the German idiom of his original.

THE King has sanctioned the following promotions in and appointment to the Order of the Hospital of St. John of Jerusalem in England: Colonel Charles Robert Tyrrell (from Esquire) and Mr. Richard Henry Grimbly (from Honorary Associate) to be Knights of Grace; Major Sir Edward Scott Worthington, M.V.O., R.A.M.C., to be an Esquire.

THE MORTALITY ON THE RAND: SOME OF ITS CAUSES.

BY B. G. BROCK, L.R.C.P. & S. EDIN., D.P.H.

So much has been said and done from the therapeutic side in the hope of reducing the appalling death-rate on the Witwatersrand goldfields, without to any appreciable extent improving matters, that the time has come when an examination of the underlying causes of this mortality may be made with profit, inasmuch as should it be possible to bring these clearly into the light they may automatically reveal the trend of the measures which should be taken to remove them, or at least reduce their evil influence to a minimum.

The diseases chiefly responsible for the abnormal mortality are pneumonia and tuberculosis; the following remarks therefore apply more especially to these. Elsewhere[1] it has been shown that 80 per cent. of the natives coming to work on these fields suffer from a constitutional "taint" which renders them peculiarly susceptible to contract both pneumonia and tuberculosis in a virulent form. In that paper it was stated that in 7660 natives examined 68·5 per cent. had enlarged epitrochlear glands. In a further examination of 132 consecutive cases of natives returning home and certified as suffering from the diseases under which they are grouped by various medical officers, the percentages having enlarged, indurated, freely movable epitrochlear glands are found to be—

91	cases of	tuberculosis	=	100 per cent.
31	„	"debility"	=	87 „
10	„	pneumonia	=	90 „

showing clearly that these diseases found a very favourable soil in persons having this gland enlarged.

In an examination of 191 white persons (105 males and 86 females) of South African birth the condition was found in 30 per cent. of males and 10 per cent. of females.[2] In a paper read before the International Congress of Medicine, London, 1913, Mrs. Fuchs von Wolfring records that she examined 44 cases of tuberculosis, using Carl Spengler's methods of blood staining, and found spirochætæ in 100 per cent. of them.

Carl Spengler has been directing his attention to this question for over 20 years, and has now arrived at the conviction that numberless tuberculosis cases develop in the hereditary syphilitic constitutions. Those organisms already damaged by the syphilitic poisons are predisposed to tuberculosis. ("Tuberculose-Therapie nach Dr. Carl Spengler, mit besonderer Berücksichtigung des I-K," von Dr. Bonohr, Assistent von Dr. C. Spengler, published in the *Beiträge zur Klinik der Tuberculose.* Band xvi. H. 4. 1910.[3])

---

[1] THE LANCET, May 11th, 1912, p. 1270.

[2] The marked difference in the percentage of the sexes suggested the question, Are the seats of election for "latent syphilis" different in man and women? My own experience of over 23 years in South Africa suggests that in woman the uterus may be such a "seat," on account of the great frequency of various forms of "metritis" in otherwise apparently healthy women. In the books of an institution I was privileged to examine, excluding all cases resulting from accident and childbirth, out of a total of 42 cases there were 6 cases of abortion, 2 of "curetting," 5 of retroflexion, 1 of perimetritis, and 13 of endometritis, or 64 per cent. of the cases that may be considered as resulting from pathological conditions of the body of the uterus. In the Epitome in the British Medical Journal of August 4th, 1912, under the heading "Uterine Sclerosis," Swedey is noted as saying that uterine sclerosis is not rare in young women, that the condition is often mistaken for metritis or fibroids, and that Richalet has proved this. The figures given are those supplied by me in evidence before the Tuberculosis Commission on May 1st, 1912.

[3] For the translation of an extract from this paper, and a number of extracts from the works of Carl Spengler on the same subject, and for directing my attention to them, I am indebted to Miss K. Ives.

For a good many years there have been repeated warnings from medical men in South Africa of the increasing spread of syphilis among the white population, as the result of careless relations with the black races. Further, it is a generally accepted view that South African born natives are more susceptible to pneumonia and tuberculosis than are those from other countries, and that they succumb to these diseases much more quickly than do the latter. It may therefore be presumed that a constitutional "taint" is so widely prevalent in both races that it is unnecessary to consider them separately in this respect, and that the mining population as a whole is badly prepared constitutionally to withstand an attack of either pneumonia or tuberculosis and is abnormally susceptible to both diseases.

Altitude.

In the case of natives coming from the coast or other place of low altitude to the Rand great changes occur in the blood. The normal number of red cells per cubic millimetre at sea level is roughly 5,000,000, while on the Rand, 6000 feet above sea level, it is from 7,000,000 to 7,500,000. It takes from 14 to 20 days after arrival on the Rand for the blood to reach this standard. During this time the oxygen-carrying capacity of the blood must be below normal, and the tissues, receiving an insufficient supply, must be thereby reduced in disease-resisting power. Carl Spengler has shown that the *red* cells are the main producers and storehouses of tubercle antitoxin,[4] often containing a million times more than the corresponding serum. The white cells contain less than the red but more than the serum. While the red cells are not in a normal condition they cannot perform their functions normally, and the production of antitoxin must be injuriously interfered with.

These facts would appear to supply the explanation of the oft-repeated observation that "boys" are much more liable to contract pneumonia and tubercle during the first two or three weeks of their stay on the Rand than later. Some hold that the greatest number of cases of sickness occurs in the first 24 hours, but the fact that the mass of native workers come off a long and tiresome journey, without the opportunity of getting any rest, and are drafted at once to their various destinations along the "Reef," suggests that many of these "first 24-hour" cases are probably due to simple exhaustion. It has further been found that there is a direct proportional relation between the amount of hæmoglobin and the amount of immune substances in the blood. It seems therefore probable that if special care were taken of the "boys" during the transitional period it might materially aid in reducing the sickness-rate and increase the chances of escaping pneumonic and tuberculous infection. What amount of injury results to the blood, if any, from the men spending half the day at an altitude of 6000 feet and the other half at from 1000 to 3000 feet there are no data to indicate.

Conditions of Living on a Mine.

To ensure a standard of health sufficiently high to enable the individual day after day to perform a fair day's work in quantity and quality three things are essential—sufficient food, sufficient rest, and sufficient warmth (clothing, bedding, &c.). In the case of the white man, whether these essentials are obtainable under the working conditions on a mine depends mostly on himself—e.g., a man comes "off shift" and without changing or washing cycles to his home in the "single men's quarters," gets into his room, and tumbles into his bed without even removing his working clothes, "refreshes" himself thoroughly and goes to sleep and gets a chill. On recovering he is unable to take sufficient food. This goes on day after day till pneumonia claims a victim.

A steady hard-working-man after "coming off" changes, bathes, and returns to his room, which is often shared by another miner who may be a case of open tuberculosis, who will not permit either window or door to be kept open; he "turns in" and goes to sleep in an atmosphere of tuberculous vapour. In due time tuberculosis claims an innocent victim. These rooms are mostly of the back-to-back type, and are dirty and verminous, making restful sleep impossible. A considerable number of men, again, are very "free livers," who run needless risks from exposure, disease, and other debilitating influences. From the ranks of these comes a goodly number of cases of tuberculosis and pneumonia.

The case of the native is somewhat different. The standard ration is: 20 oz. mealie meal, 8 oz. wheat bread, and 4 oz. beans (dried) per day; 3 lb. "meat," 22 oz. pea nuts, 16 oz. treacle, and 40 oz. vegetables per week. This ration is added to in some of the mines. There seems to be a good deal of difference of opinion as to the suitability of this ration. It is a ration built entirely on its calorie value, it is not a toothsome diet, there is a considerable waste in unconsumed food, and there is a considerable amount that is not digested or assimilated, while Casimir Funk has shown that the manner of cooking may influence the value of a diet. The compilation of an *efficient* diet is undoubtedly difficult and can only be attained by direct experiment. A "boy's" clothing usually consists of a blanket—often a mere rag, a pair of trousers, and a shirt. His bed—plain wooden boards without bedding. The "compound" room in which he eats and sleeps is a large draughty barn, under-heated and over-ventilated, always dusty, often dirty and verminous. Comfort there cannot be, and under the conditions warmth and restful sleep are well-nigh impossible. Add to this that the native is extremely sensitive to cold, and that in winter there may be as much as 20° F. between the wet and dry bulb thermometers, and the least imaginative will realise that the most robust constitution is liable to break down under such treatment. How are those who are constitutionally susceptible to pneumonia and tuberculosis to pass through such an ordeal unscathed? They cannot and do not. These are the places where, and the conditions under which, pneumonia and tuberculosis spread, flourish, and destroy.[5]

Is it lack of knowledge, simple thoughtlessness and lack of sympathy, or downright callousness that permits such conditions to exist? Probably some of each. The "great expense" has been a reason against any change. But when the problem is examined carefully one cannot help thinking that all the necessary changes would not only not raise the "working costs" of a mine, but would prove to be an investment that would return a handsome dividend.

---

[4] Spengler's work has been confirmed by S. Fuchs von Wolfring, Dr. Rachmaninoff, Dr. Rossel, and Dr. G. Fuchs, of Beibrich, in over 1000 different specimens of blood, also by Sewastianoff.

[5] Since this was written I have been informed that owing to the shortage of "boys" recently the compounds are less crowded than usual, and that there has been a very marked fall in the sickness rate.

Working Conditions.

Little need be said on these. Dust, carbonic oxide, and nitrous fumes should, of course, be reduced to a minimum by improved ventilation and increased care; but no matter how stringent regulations may be, in the nature of things they will still exist in all the mines to some extent, and the two latter probably continue to do some harm, the CO by putting some hæmoglobin "out of action," and the fumes by causing some bronchitis, thereby lowering the resisting power against bacterial attacks locally and generally. The dust that might remain in a well-ventilated mine would be of little account. Oliver in his "Diseases of Occupations," p. 293, gives an excellent illustration of this. He quotes from a report by Dr. Brembridge on the Kolar gold mines in India to the following effect:—

> In the Kolar gold mine there are 40,000 coolies employed; the rock is hard. Dr. Brembridge went to India expecting to meet with cases of miner's phthisis, but he failed to find evidence of the disease, except in men who came from the Transvaal. Although no precautions are taken in the Kolar mines to throw water on the surface to diminish the dust after the use of explosives, and the men work hard, yet Dr. Brembridge finds that the miners, native and white man, keep good health. ...... There is plenty of dust in the Kolar mines; it is hard quartz rock that is blasted, and without such precautions as the spraying of water. ...... Dr. Brembridge finds that a large percentage of miners die from pneumonia, due not so much to the dust as to the fact that the men, after working hard for eight hours, are obliged to climb ladders to a height of 2000 feet in a state of fatigue and when perspiring, and thus become chilled. The proof that this has had much to do with the prevalence of pneumonia has been demonstrated by the fact that since a skip, whereby the coolies can ride to the surface, has been introduced into one of the mines from which the largest number of cases of pneumonia came, the number of cases of acute lung disease has considerably diminished.

Here, too, this cause of pneumonia to some extent exists, but here the "boys" come from the warm moist mine into an exceedingly dry and cold air—indeed, it may be compared to putting them into a freezing chamber.

A glance at some of the "rates" for Germiston district helps to bring out the importance of the above remarks. In the following table the incidence rate for pneumonia and the death-rate for phthisis (tuberculosis and miner's phthisis) for three years are given for three races then working on the mines. Underground they all worked under the same conditions and were exposed to the same dangers, save that the native was less well protected against chills on coming to the surface than were the other two races.

—	Whites.			Natives.			Chinese.		
	1905-06	1906-07	1907-08	1905-06	1906-07	1907-08	1905-06	1906-07	1907-08
Pneumonia incidence per 1000	2·30	2·54	3·43	25·04	29·37	55·07*	2·05	1·37	1·96
Phthisis deaths per 1000 (tuberculosis and miner's phthisis)	2·23	2·45	1·23	4·94	3·67	3·63	1·53	0·87	1·71

* The importation of natives from the tropics caused the very great increase in the rate for this year. For all the three years a good many cases of tuberculosis in natives came under this head.

These figures show that the natives suffered more than the other races. In the case of whites and natives the figures for "phthisis" are very much below what actually existed on account of the whites going and the natives being sent out of the district when they became unfit for mine work. Nevertheless, the Chinese, although the full rates are recorded, show lower figures than black or white. How is this to be explained, seeing that the Chinese occupied the same compounds as the natives occupy now? The Chinese had better food and it was well cooked, while their sleeping quarters were conspicuous for their *apparent* cleanliness and the great care taken to procure personal comfort, good warm bedding and bed clothes, and plenty of these. They did not consume their food in their sleeping quarters, and were not in the habit of indulging to excess in intoxicating drinks as the other races were. The figures speak eloquently in favour of sufficient food, sufficient warmth, and sufficient rest. There are others that might be considered, but those dealt with seem to me to be the outstanding causes which lead up to a death-rate unparalleled in any civilised country, and the bringing clearly into view the framework on which they rest discloses the means by which they may be removed or modified, and this death-rate brought more into line with those obtaining for similar industries in other parts of the world.

Conclusions.

1. The "Reef" population is, as a whole, abnormally susceptible to pneumonia and to tuberculosis, and constitutionally badly prepared to withstand the attacks.

2. The change from a low to a high altitude disturbs the physiological equilibrium of the blood of new arrivals on the Rand, and renders them extremely susceptible to disease until this equilibrium is re-established.

3. Putting new arrivals to heavy work before this physiological equilibrium is established (about three weeks) increases the sick lists and raises the death-rate.

4. The great dryness of the air in winter causes much pneumonia, especially in those coming "off shift," unless effective protective measures are provided and enforced.

5. The natives are underclad and do not receive sufficient rest or sleep, and their food requires investigation as to its physiological efficiency and proper cooking.

6. The causes which are responsible for the abnormal death-rate are capable of removal in large measure, and the chief supports of these are—false economy and callous inefficient administration.

ROYAL INSTITUTION.—At a general meeting of the members of the Royal Institution held on April 6th the Duke of Northumberland, as President, announced that the septennial award under the Acton Endowment had this year been made to Professor C. S. Sherrington, Waynflete professor of physiology in the University of Oxford, for his important work entitled "The Integrative Action of the Nervous System." This work was a synopsis of an elaborate paper published in the Philosophical Transactions of the Royal Society on Experiments in Examination of the Peripheral Distribution of the Fibres of the Posterior Roots of some Spinal Nerves.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

AN Extraordinary Comitia was held on Monday, April 6th, Sir THOMAS BARLOW, the President, being in the chair.

The PRESIDENT delivered the usual annual address, in which he referred to the Royal honours which had been conferred on Fellows, Members, and Licentiates during the past year; also to the Harveian oration and the lectures which had been delivered before the College. He also alluded to the award of medals and prizes, and the various events within the College. He likewise mentioned the gifts which had been made to the College. He read obituary notices of the Fellows who had died during the year:—George Ernest Herman, Robert Leamon Bowles, Frank Buszard, John Charles Thorowgood, Alfred Lewis Galabin, and Philip Frank. He thanked the Censors' Board and the other Fellows for their unfailing loyalty during the past year, and then vacated the chair.

Dr. P. W. LATHAM proposed a vote of thanks to the President for his address, and for his services to the College, which was carried by acclamation.

The ballot for the election of President then took place, and Sir Thomas Barlow was re-elected by a large majority.

The Senior Censor (Sir James Kingston Fowler) delivered to the President the insignia of office. The President gave his faith to the College and thanked the Fellows for re-electing him.

The following communications were received: (1) From the secretary of the Royal College of Surgeons (three letters); (2) from the clerk to the Privy Council, dated March 5th, to inform the College that the Sixth International Congress on Thalasso-Therapeutics will be held at Cannes on April 15th; (3) from the secretary of the Board of Control, dated March 25th, asking for suggestions concerning the use of a grant of money "for the purpose of aiding and encouraging scientific research into the causes and treatment of mental disease and mental defects." The President was asked to nominate a subcommittee who should report to the Council.

A report was received and adopted from the Censors' Board, dated March 2nd, concerning the employment of unqualified persons for purposes of treatment under the National Insurance Act. The report was as follows:—

> In the course of last year communications passed between the Censors' Board and the Insurance Commissioners on the subject of the employment of non-qualified persons under the Insurance Act. The contention of the Commissioners appeared to be that, while none but registered medical practitioners are admissible to the panels, yet there was nothing in the Act of 1911 to prevent insured persons who are allowed or required to make their own arrangements for medical benefit from making such arrangements with persons who are not legally qualified medical practitioners.
>
> More recently the Commissioners "for the purpose of removing doubts and for the convenience of Insurance Committees" have altered the Regulations in this respect, and in their new Regulations [National Health Insurance (Medical Benefit) Regulations, 1913, Section 44 (2)], and in a "Memorandum with regard to persons making their own arrangements under Section 15 (3) of the National Insurance Act, 1911," the possibility of treatment by unqualified persons under this Section of the Act is specifically recognised, and provisions are made with respect to it.
>
> The President and Censors consider that to give to unqualified persons any status whatever under an Act of Parliament is an innovation which should not pass unnoticed by the College.
>
> They therefore submit the following Resolution for the consideration of the College:—
>
> NATIONAL HEALTH INSURANCE (MEDICAL BENEFIT) REGULATIONS, 1913.
>
> The College observes with regret that in Section 44 (2) of the National Health Insurance (Medical Benefit) Regulations, 1913, and the Memorandum issued in connexion therewith, provision is made whereby insured persons who make their own arrangements for Medical Benefit under Section 15 (3) of the National Insurance Act may obtain treatment from non-qualified persons.
>
> Hitherto none but duly qualified medical practitioners have been employed, as such, in any public capacity, and the College deplores that now, under an Act professing to promote the health of the nation, recognition should be given and provision made for the payment of public money to a class of persons who have not obtained a legal qualification to practise medicine, and concerning whose medical knowledge there exists no sort of guarantee.

A report, dated Feb. 12th, was received and adopted from the committee nominated July 3rd, 1913, concerning the infectivity of pulmonary phthisis. The report summarised accepted knowledge upon the infectivity of tuberculosis, and indicated that the tubercle bacillus could enter the body by inoculation, by inhalation, and by swallowing, while it emphasised the absence of evidence that tuberculosis can be conveyed by breath alone, or by emanations from patients, or by their garments unless soiled by discharges. The precautionary measures recommended are: the careful disposal and disinfection of the sputum and other discharges; the disinfection or destruction of soiled handkerchiefs, clothes, and linen; the removal of dust by frequent moist cleansing of floors and walls; and abundant air space and free ventilation. The report closes by stating that no risk is incurred by living in the immediate neighbourhood of institutions for the treatment of tuberculosis which are properly conducted.

The committee of management reported that Sir W. Watson Cheyne had inspected the examinations of the Egyptian Medical School, and a vote of thanks was accorded to him for his services. The committee also reported that Wellingborough School and the Bradford Technical College had been added to the list of institutions recognised by the Conjoint Board as giving instruction in chemistry and physics and biology respectively, and recommended that the Royal Naval Hospital, Chatham, should be recognised for the instruction necessary for the diploma in public health.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the twenty-seventh meeting of the Royal Commission on Venereal Diseases evidence was given on behalf of the Society of Medical Officers of Health by Dr. A. K. Chalmers, the medical officer of health of Glasgow and president of the society, and by Dr. Louis C. Parkes, medical officer of health of Chelsea.

They drew attention to—

1. The lack of exact information regarding the present prevalence of syphilis and other venereal diseases either as causing illness or death.
2. The misleading or incomplete character of certified causes of death, particularly of the remote causes in death from diseases of the nervous or circulatory system.
3. The absence generally of any systematic provision for the recognition and treatment of the diseases in question.
4. The relationship of syphilis to miscarriages, still-births, and deaths among infants in the first year of life, especially the first four weeks.

The Society of Medical Officers of Health were, they stated, of opinion that administrative action was desirable for the purpose of providing facilities for the recognition and treatment of venereal diseases. They recommended that the local authorities should be required to place at the disposal of medical practitioners facilities for diagnosis by bacteriological and other methods, and that accompanying any such request for examination the practitioner should apply a statement showing the age, sex, condition as to marriage, number of children, and leading features of the disease present, but not including the name of the patient. They did not recommend the adoption of a system of notification in the ordinary sense. Local authorities should also be prepared to arrange for the treatment of persons suffering from venereal diseases either in dispensaries or hospitals under their own responsibility or by arrangement with general hospitals and dispensaries. It was important, they thought, that the facilities provided by the local authority should be available for any person who applied for them, whether that person was a resident in the district of the local authority or not. They recommended that the Local Government Board should issue an order declaring venereal diseases to be endemic diseases threatening the health of the population, and that the Board should make regulations governing the provision of facilities by the local authorities. It was necessary, they thought, that the local authorities should be assisted by a considerable grant in aid from Government funds.

Dr. Parkes on his own behalf submitted a detailed scheme of action by local authorities under regulations to be issued by the Local Government Board. He was of opinion that the whole expenditure incurred by local authorities in regard to these diseases should be borne by Imperial funds. Both Dr. Chalmers and Dr. Parkes were opposed to notification of venereal diseases, but Dr. Parkes thought that after two or three years' experience of systematic action by local authorities against the diseases it would be possible to determine whether any form of compulsory notification could be introduced, and whether penalties should be imposed upon persons who, knowing themselves to be suffering from a venereal disease, by their conduct expose other persons to infection.

At the twenty-eighth meeting evidence was given by Sir Donald MacAlister, Principal and Vice-Chancellor of the University of Glasgow, and President of the General Medical Council.

Sir Donald MacAlister described the powers of the General Council in relation to medical education and the way in which these powers are exercised, for the securing the maintenance of such a standard of proficiency as shall guarantee the possession by registered practitioners of the knowledge and skill requisite for efficient practice. With regard to instruction respecting venereal diseases, he said that certain reports made to the General Medical Council and the examination papers used at qualifying examinations, as well as the results of a special inquiry he had made for the purposes of the Commission, enabled him to say that questions on these subjects were set with such regularity by every licensing body that candidates could not fail to be aware of the importance attached to the subject and of the necessity laid upon them to study it seriously as a condition of success.

On the subject of quack treatment Sir Donald MacAlister said that the General Council had taken every opportunity to press on the Government of the day the importance of restricting the free practice of medicine, surgery, and midwifery by unqualified persons, and the Council was strongly of opinion that steps ought to be taken to prevent the cruel wrong done by permitting free practice in branches of these subjects on the public without any previous qualification. He pointed out that without difficulty veterinary surgeons had obtained an Act which protected them and protected the lower animals, so that no person could use any title suggesting that he had a veterinary qualification or practise as a veterinary surgeon on the lower animals without being qualified. In fact, Parliament had protected the lower animals much more effectively than it had protected human beings against the ravages of the quack. He thought that a special case could be made out for preventing unprofessional treatment of venereal diseases by reason of the severity of these diseases and their effect upon the population.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on April 2nd, Sir RICKMAN GODLEE, the President, being in the chair.

The SECRETARY reported the death of Mr. William Bruce Clarke, past member of the Council and of the Court of Examiners.

The best thanks of the Council were given to Sir Watson Cheyne for his services as visitor to the examinations of the Egyptian Medical School at Cairo.

In accordance with the recommendation of the Jacksonian Committee the Jacksonian prize for the year 1913 was awarded to the author of the dissertation on "Malformations of the Small Intestine: their Mode of Origin, the Morbid Conditions which Arise from Them, and their Treatment," bearing the motto "Aliud ex alio clarescet," and when the President opened the envelope bearing this motto it was found that the author was Mr. J. Howell Evans. It was resolved to request Mr. Evans to attend the ordinary meeting of the Council on May 14th to receive the Jacksonian prize.

It was resolved that the subject for the Jacksonian prize for the year 1915 should be "Congenital Dislocations of the Joints: their Pathology and Treatment."

Surgeon-General Arthur William May, C.B., R.N., Medical Director of the Navy, was elected a Fellow of the College.

A letter was read from Mr. J. Richardson Cross reporting his attendance at the Home Office on Jan. 29th to give evidence before the Committee on Factory Lighting as requested by the Council, and stating that in support of his evidence he was able to lay before the committee answers to a letter circulated by him among members of the Ophthalmological Society bearing on the questions under consideration. The thanks of the Council were given to Mr. Cross for his letter.

A letter was read from the General Secretary of the Sixth International Dental Congress stating that the Committee of Organisation accept with thanks the offer of the Council to hold a reception at the College for the members of the Congress.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of Middlesex.—Dr. C. W. F. Young's report for 1912, recently issued, gives a large amount of interesting information on the health and administration of this county, which, though small, is one of the most populous of the county areas. The estimated number of inhabitants is about 1,170,000, of which all but 58,000 are in "urban" districts. The various statistical data for the county as to births, incidence of infectious disease, case mortality of infectious diseases, and deaths from different causes are well illustrated by diagrams which save much study of tables. The decline in the mortality of notified cases of diphtheria from 1902 to 1912 is specially noteworthy, but it has to be remembered that the extension of bacteriological methods in the diagnosis of diphtheria leads to an increasing amount of notification of illness the nature of which would not otherwise have been recognised, and also that "contacts" presenting no symptoms of illness at all, but returned as "positive" on a swab examination, are now frequently included among notified cases. Dr. Young insists on the importance of bacteriological examinations being made of all school children with sore-throat or nasal discharge during their attendance at school, and urges that closure of school for diphtheria will only disperse the children where they cannot be kept under supervision or frequent examination, with the result that on re-opening some will probably still be in an infective condition. This doctrine is now generally accepted, and it is interesting to note that the practical experience of Middlesex schools gives support to it. The tables for whooping-cough show that, to judge from the mortality returns, this disease shows little tendency to reduced prevalence, and some 200 deaths are returned annually as due to this cause. The development of tuberculosis provision is only touched upon in this report, but a map is inserted of the five areas into which Middlesex has now been divided for the purpose of a county dispensary service. A table showing the methods of disinfection in use in each district in the county illustrates the large extent to which the formalin spray has displaced sulphur dioxide fumigation as a means for disinfecting rooms, the latter being now retained in only three or four of the 37 districts. Eleven of these districts now dispose of their house refuse by combustion in destructors, and the extension of this practice is specially desirable in a county like Middlesex, where it is hardly possible to get rid of refuse by depositing it on land without giving rise to effluvium nuisance. Another matter closely affecting the health and amenities of the county is the condition of the small rivers which have to receive large volumes of effluent from sewage disposal works. The county council and its medical officer of health have in the past done much to prevent the discharge of offensive sewage into these streams, but it is clear that continued vigilance is necessary in consequence of the large increase of populations on the watersheds and the tendency of local bodies to provide inadequate purification plants. The proportion of the total births attended by midwives, apart from those in which the midwife merely acted as a nurse, is considerable—11,020 out of 27,576. Notifications that medical help had been requisitioned were received in regard to 853 of these cases.

No death of a mother occurred where a doctor had not been called in. A prosecution of an uncertified woman was dismissed by the magistrates on the ground that the six confinements which she had attended were emergency cases, as she had not been engaged beforehand by the mother and was only sent for when the mother was in labour. On representation of the matter to the Central Midwives Board the county council was informed that the same state of affairs had been brought to notice before, and that there was reason to believe that the Privy Council, on the Board's recommendation, were prepared to amend the Midwives Act so as to strengthen the powers of local supervising authorities in this respect.

County of East Sussex.—Mr. A. G. R. Foulerton, after referring to the perennial difficulty in obtaining reports from some district medical officers of health early enough for county purposes, points out that in health matters East Sussex is a well-favoured county, and was particularly so favoured in 1912. The only excessive rate was that from "senile mortality," and though the birth-rate is low (17·4) the children as a rule "are born to healthy surroundings and are not likely to be killed off during the first year of life by the insanitary conditions prevailing in large industrial districts which have higher birth-rates and huge infantile mortality rates." The tuberculosis death-rates are among the lowest of the English counties. Mr. Foulerton finds that the prevalence of pulmonary tuberculosis in children is exceptionally low, as in the case of 24,000 children "thoroughly examined" in course of school medical inspection the percentage with pulmonary tuberculosis was no higher than 0·04.[3] The report, besides giving useful accounts of the different districts, has some interesting addenda. One of these gives notes on the statistics and etiology of cases treated in the county lunatic asylum, supplied by the medical superintendent. Another is contributed by the Lewes coroner, Mr. G. V. Benson, on the circumstances of the 281 inquests held in 1912, one being on a partly disabled workman who, after worrying himself trying to understand the Insurance Act regulations as to unemployment, "came to the conclusion that they might be prejudicial to him in the future, and that it was better to get rid of the risk by throwing himself over the cliff." A third addendum, by Mr. George Finch, gives the results of examining the arms of children in different districts for vaccination scars, and includes diagrams in which the percentage of children vaccinated are plotted against the year of birth, and which show conspicuously the fall in vaccination which set in after 1907 and has continued since. The fall, Mr. Finch observes, may continue until perhaps in future the vaccinated may form a smaller proportion of the population than formerly did the pock-marked; medical officers of health and sanitary authorities would then have to deal with a population more susceptible to the virus of small-pox than has ever been the case before.

County of Hampshire.—In considering the supervision of the milk-supply and its present defects Dr. R. A. Lyster presses strongly for general certification of milk, and states that proper milk standards are not only necessary to efficient milk control by public health authorities, but are indispensable to the ultimate well-being of the milk industry itself. Milk, he considers, must be graded and sold on grade, just as other food materials are graded and sold. For grading purposes milk would best be divided into two great classes—the raw and the pasteurised varieties. Each class can be divided into grades according to its composition and its bacteriological purity. The county had a low rate of infant mortality in 1912, and in referring to the circumstance that the incidence of this mortality was higher among the poor Dr. Lyster protests against the assumption that bad housing is concerned in the matter, and reminds us that statistics classifying the people according to housing conditions is merely a classification according to poverty. The essential cause of excessive infantile mortality is poverty with "its invariable accompaniments—insufficient food for both mother and child, lack of medical attention or nursing, absence of suitable milk-supply, even if there were means to purchase it, uncleanliness, overcrowding, alcoholic indulgence, and such like." It is possible to agree with this view and still to find a preventable cause of infant mortality in "bad housing," which may be inimical to cleanliness, and may be largely responsible both for overcrowding and for alcoholic indulgence. The county death-rate for tuberculosis, which was 0·91 in 1910, has since shown a slight increase to 1·04 in 1912; that of the rural districts is now higher than that of the urban, and as high as it was ten years ago. The increase is attributed partly to the migration of diseased persons into rural districts after their condition is known. The report advocates that discarded warships, the position of which could be changed according to the weather and temperature at different times of the year, should be used as sanatoriums. In course of the county laboratory work a specimen of home-made wine was received which was suspected to have caused lead poisoning. This was analysed and found to contain 2·9 parts of lead per 100,000, and is stated to have been contaminated by lead from the glaze of the earthenware pan in which it was made.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Borough of Kingston-upon-Thames.—Mr. H. Beale Collins records the beginning of an inquiry into the relationship between physical development of children and size of families. In children coming from families of six only in 71 instances they were above normal and in 80 below it. Contrasting entrants and leavers the figures point to a decline in size of families. The biggest "leaver" family was 22, the biggest entrant, however, only 14. The tables, however, have not much scientific value as they stand, as the criterion of "physical condition" is not rigidly defined and appears to refer only to standards of weight and height. Very little medical treatment is obtained, only about one-quarter of the children found defective obtaining it.

County Borough of Barnsley.—Dr. F. J. Sadler's report on the Queen's-road open-air school shows that it is reserved exclusively for children suffering from pulmonary tuberculosis. Of 62 children who were treated for a time sufficiently long for a judgment to be formed, 11 per cent. were improved, 45 per cent. improved very much and on the way to a cure, and 35 per cent. actually cured. One child died while attending the school, but from leucocythæmia. These satisfactory results were obtained by keeping the school open winter and summer, and have led the education committee to consider modifying the ordinary schools in the direction of the open-air school.

Borough of Newcastle-under-Lyme.—There are only five schools in the borough. Dr. John Fortune's report as school medical officer is incorporated with his report as medical officer of health. An inspection clinic is held daily. Only 33 per cent. of the defective cases obtain treatment, and this number includes cases of pediculosis. The figures do not seem to call for any congratulation of the borough.

County Borough of Bournemouth.—Dr. A. D. Edwards comments on the number of "delicate" children in the schools, which he associates with the character of the population attracted to Bournemouth. Ten such cases were taught in the open air during the year, with great benefit. The importance of abnormal restlessness as a possible early sign of rheumatism is commented upon. Of 10,000 children examined less than 6 per cent. have had growing pains. The report has an interesting psychological side to it.

County Borough of Brighton.—Brighton has 33 schools, including one for the mentally defective, and an average attendance of 16,417. Of 6318 children examined, 18·6 per cent. were in need of medical treatment, and a large number of dental cases appear to be excluded which in other localities would swell the percentage very largely. Teeth are considered "good or fair" if *not more than six teeth are carious.* The italics are our own and the figures are likely to mislead. The London County Council standard for normal is not more than three carious teeth, and dentists protest against this. Medical treatment is carried out by the senior school doctor, Dr. C. W. Hutt, and by a school dentist. Contagious skin diseases, refraction work, X ray work, and operations for removal of tonsils and adenoids are all dealt with.

County Borough of Eastbourne.—The birth-rate in Eastbourne is decreasing, so that the number of school children is less than that in previous years. In 27·2 per cent. of children inspected advice for defects was given, and in 80 per cent. treatment was secured. A school nurse follows up the inspection by visits to schools and homes, and treatment for defective vision, teeth, and ringworm (through a

---

[3] THE LANCET, March 28th, 1914, p. 916.

"ringworm school") is given by the authority. The total number of children inspected was 2342. Out of 1140 boys, 291, or 25·53 per cent., were employed out of school hours. The cases are specially reported on, and show the need for a different method of "following up" such children. Even in flagrant cases reported by Dr. W. G. Willoughby the police did not prosecute.

City of Leeds.—Dr. Algernon E. L. Wear is assisted by 12 assistant medical officers and one school nurse, and his report is prefaced by a note from Mr. James Graham, secretary of education in the city, making out a strong case for support by the Treasury. The school nurse examined 20,378 children. A comparison of weights with boys in the Leeds Grammar School at age 12 gives: National Standard (presumably anthropometric committee), 76·7 lb.; Leeds Grammar School, 75·7 lb.; Municipal Secondary School, 73·5 lb.; and Elementary School, 70·5 lb. Jewish scholars approach most nearly to the country average. The corresponding heights are 54·9, 57·1, 55·7, and 53·8 inches.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 97 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 8932 births and 5741 deaths were registered during the week ended Saturday, March 28th. The annual rate of mortality in these towns, which had been 15·8, 15·4, and 15·2 per 1000 in the three preceding weeks, rose to 16·5 per 1000 in the week under notice. During the 12 weeks of the March quarter the mean annual death-rate in these towns averaged 16·4, against 16·1 per 1000 in London during the same period. Among the several towns the death-rate in the week under review ranged from 5·1 in Edmonton, 6·9 in Ilford, 7·3 in Devonport, 7·5 in Eastbourne, and 8·0 in Grimsby, to 22·7 in Burnley, 23·3 in Preston, 23·5 in Stoke-on-Trent, 25·3 in Swansea, and 30·0 in West Bromwich.

The 5741 deaths from all causes were 455 in excess of the number in the previous week, and included 488 which were referred to the principal epidemic diseases, against numbers rising from 397 to 444 in the five preceding weeks. Of these 488 deaths, 162 resulted from whooping-cough, 140 from measles, 73 from diphtheria, 65 from infantile diarrhœal diseases, 33 from scarlet fever, and 15 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·4, against 1·3 per 1000 in each of the two preceding weeks. The deaths attributed to whooping-cough, which had steadily increased from 110 to 155 in the five preceding weeks, further rose to 162, and caused the highest annual death-rates of 1·3 in Leicester, 1·5 in Sheffield, 1·6 in Rotherham and in Middlesbrough, 1·7 in Exeter, in Bolton, and in Newport (Mon.), 1·9 in Barnsley, and 2·6 in Swansea. The deaths referred to measles, which had been 118, 113, and 107 in the three preceding weeks, rose to 140 in the week under notice; the highest annual death-rates from this disease were 1·4 in West Ham, in Ipswich, and in Cardiff, 1·6 in Bradford, 1·9 in Burnley, 2·3 in Nottingham and in West Bromwich, 2·9 in Leicester, and 3·9 in Swansea. The fatal cases of diphtheria, which had been 60, 67, and 51 in the three preceding weeks, rose to 73, and included 12 in London, 10 in Birmingham, 4 in Manchester, and 3 each in Cambridge, Liverpool, and South Shields. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 59, 74, and 73 in the three preceding weeks, declined to 65; of this number 17 were registered in London, 5 in Manchester, and 3 each in Birmingham, Liverpool, and Middlesbrough. The deaths referred to scarlet fever, which had been 34, 31, and 37 in the three preceding weeks, fell to 33 in the week under notice, and included 10 in London and 3 each in Liverpool, Salford, Preston, and Sheffield. The fatal cases of enteric fever, which had been 20, 13, and 21 in the three preceding weeks, fell to 15, of which 2 occurred in Gillingham.

The number of scarlet fever patients under treatment in the London Fever and the Metropolitan Asylums Hospitals, which had steadily decreased from 3593 to 3173 in the eight preceding weeks, had further declined to 3143 on March 28th; 347 new cases were admitted during the week, against 340, 320, and 319 in the three preceding weeks. These hospitals also contained at the end of the week under notice 1237 cases of diphtheria, 356 of whooping-cough, 134 of measles, and 77 of enteric fever, but not one of small-pox. The 1433 deaths from all causes in London were 235 in excess of the number in the previous week, and were equal to an annual death-rate of 16·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 260, [illegible], and 250 in the three preceding weeks, further rose to 291 in the week under notice, but were 101 below the number recorded in the corresponding week of last year.

Of the 5741 deaths from all causes in the 97 towns, 182 were attributed to different forms of violence, and 448 were the subject of coroners' inquests. The causes of 37, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, and in 70 other smaller towns. Of the 37 uncertified causes of death, 11 were registered in Birmingham, 4 in Liverpool, 3 in Preston, and 2 in Middlesbrough.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1204 births and 726 deaths were registered during the week ended Saturday, March 28th. The annual rate of mortality in these towns, which had been 16·6, 17·9, and 16·6 per 1000 in the three preceding weeks, further fell to 16·5 per 1000 in the week under notice. During the 12 weeks of the March quarter the mean annual death-rate in these Scotch towns averaged 18·2, against 16·4 per 1000 in the 97 large English towns. Among the several towns the annual death-rate in the week under notice ranged from 9·4 in Clydebank, 11·0 in Falkirk, and 11·1 in Leith, to 19·1 in Kilmarnock, 20·6 in Paisley, and 25·5 in Coatbridge.

The 726 deaths from all causes were 3 fewer than the number in the previous week, and included 78 which were referred to the principal epidemic diseases, against 77 and 66 in the two preceding weeks. Of these 78 deaths, 34 resulted from measles, 14 from infantile diarrhœal diseases, 11 from whooping-cough, 9 from scarlet fever, 9 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·8, against 1·4 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 35, 34, and 38 in the three preceding weeks, fell to 34 in the week under notice, and included 21 in Glasgow, 5 in Motherwell, 3 in Coatbridge, and 2 in Edinburgh. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 14, 10, and 5 in the three preceding weeks, rose to 14, of which 9 were registered in Glasgow and 2 in Aberdeen. The fatal cases of whooping-cough, which had been 10, 8, and 10 in the three preceding weeks, were 11 in the week under notice, and included 5 in Glasgow, 3 in Coatbridge, and 2 in Paisley. The 9 deaths attributed to scarlet fever, of which 5 occurred in Glasgow, were equal to the average in the earlier weeks of the quarter. The deaths referred to diphtheria, which had been 5, 14, and 6 in the three preceding weeks, rose to 9, and included 4 in Glasgow and 3 in Aberdeen. The fatal case of enteric fever was registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 126, 137, and 117 in the three preceding weeks, further declined to 111 in the week under notice; 31 deaths resulted from various forms of violence, against numbers declining from 32 to 22 in the three preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 667 births and 526 deaths were registered during the week ended Saturday, March 28th. The annual rate of mortality in these towns, which had been 19·2, 20·0, and 20·3 per 1000 in the three preceding weeks, further rose to 22·8 per 1000 in the week under notice. During the 12 weeks of the March quarter the mean annual death-rate in these towns averaged 21·5 per 1000; in the 97 large English towns the corresponding rate did not exceed 16·4, while in the 16 Scotch towns it was equal to 18·2 per 1000. The annual death-rate in the week under notice was equal to 27·2 in Dublin (against 16·5 in London and 16·1 in Glasgow), 19·6 in Belfast, 22·4 in Cork, 11·4 in Londonderry, 29·8 in Limerick, and 19·0 in Waterford; while in the 21 smaller towns the mean death-rate was equal to 21·7 per 1000.

The 526 deaths from all causes were 57 in excess of the number in the previous week, and included 67 which were referred to the principal epidemic diseases, against numbers increasing from 33 to 47 in the three preceding weeks. Of these 67 deaths, 34 resulted from measles, 12 from whooping-cough, 8 from infantile diarrhœal diseases, 6 from scarlet fever, 6 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases in the week under notice was equal to 2·9 per 1000, against corresponding rates of 1·4 and 1·8 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 4, 8, and 16 in the three preceding weeks, further rose to 34, of which 27 were registered in Dublin and 5 in Lisburn. The deaths referred to whooping-cough, which had been 9, 4, and 11 in the three preceding weeks, were 12 in the week under notice, and comprised 5 in Belfast, 3 in Dublin, 3 in Cork, and 1 in Limerick. The fatal cases of diarrhœa and enteritis (among infants under two years), which had been 12, 14, and 9 in the three preceding weeks, were 8 in the week under notice, and included 4 in Dublin and 2 in Belfast. The deaths attributed to scarlet fever, which had been 3, 4, and 6 in the three preceding weeks, were again 6, of which 2 occurred in Dublin and 2 in Belfast. The 6 deaths referred to diphtheria were 3 in excess of the average in the earlier weeks of the quarter, and included 4 in Dublin. The fatal case of enteric fever was recorded in Drogheda.

The deaths referred to diseases of the respiratory system, which had been 97, 104, and 105 in the three preceding weeks, further rose to 113 in the week under notice. Of the 526 deaths from all causes, 168, or 32 per cent., occurred in public institutions, and 4 resulted from various forms of violence. The causes of 14, or 2·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes of death did not exceed 0·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: J. C. G. Reed to the *Terror*, additional, for Bermuda Yard and Ireland Island; E. S. Tuck to the *Natal*; W. R. Trythall to the *Cæsar*; R. J. Mackeow to the *Black Prince*, on recommissioning; J. Menary to the *Lord Nelson* and for general staff duties; and E. G. E. O'Leary to the *Queen*. Staff-Surgeons: W. N. Blatcliford to the R.N. Depôt, Deal, temporary; R. R. Horley to the *Sirius*, for medical charge on voyage out, and to the *Psyche*, on recommissioning; J. C. Bringan to the *Vernon*, temporary; C. A. G. Phipps to the *Pyramus*, on recommissioning; J. H. Lightfoot to the *Sirius*, for medical charge on voyage home; and E. R. L. Thomas to the *Cæsar*, temporary. Surgeons: R. J. G. Parnell to the *Victory*, additional, for disposal; H. H. Ormsby to the *Wildfire*, additional, for Sheerness Yard and Barracks; and G. B. Cockrem to the *Black Prince*, on recommissioning.

ARMY MEDICAL SERVICE.

Major William R. Blackwell, R.A.M.C., to be a Deputy Assistant Director-General at the War Office, vice M. H. G. Fell (dated April 1st, 1914).

ROYAL ARMY MEDICAL CORPS.

The undermentioned are restored to the establishment:—Supernumerary Lieutenant-Colonel Charles A. Young, vice F. J. Morgan (dated April 1st, 1914). Supernumerary Major Albert E. Hamerton, D.S.O. (dated March 28th, 1914). Supernumerary Lieutenants: William K. Morrison, Edgar Percival (dated April 1st, 1914), and Stanley J. Linzell (dated April 4th, 1914).

Colonel C. Birt has embarked for India.

Lieutenant-Colonel T. du B. Whaite has embarked for a tour of service in India. Lieutenant-Colonel F. J. Morgan has been appointed Senior Medical Officer at the Royal Arsenal, Woolwich. Lieutenant-Colonel T. B. Winter has been appointed to hold charge of the Military Hospital at Canterbury. Lieutenant-Colonel E. Eckersley has been appointed to hold charge of the Military Hospital at Quetta. Lieutenant-Colonel H. M. Adamson has been appointed to hold charge of the Military Hospital at Belgaum Cantonment.

Major R. H. Lloyd has been appointed Senior Medical Officer at the Military Hospital, Dagshai Cantonment. Major L. Addams-Williams has embarked for India. Major A. W. N. Bowen has been appointed to the Military Hospital at Belfast. Major C. E. Pollock has embarked for the Sierra Leone Protectorate. Major J. Hennessy has been appointed to hold charge of the Military Hospital at Ahmednagar Cantonment. Major J. W. H. Houghton has been appointed Specialist in Advanced Operative Surgery to the Military Hospital at Meerut Cantonment. Major A. G. Thompson has been appointed for duty on board the transport s.s. *Rohilla*, for Karachi from Southampton. Major H. W. K. Read has been appointed Senior Medical Officer at the Military Hospital, Rangoon Cantonment. Major H. D. Packer has embarked for India. Major E. W. Bliss has been appointed to the Eastern Command. Major D. Harvey has arrived home from the Nyasaland Protectorate. Major G. J. S. Archer has joined at Dorchester. Major A. H. Safford has taken up duty in the Irish Command. Major N. H. Ross has been appointed to the Military Hospital at Fyzabad. Major A. L. Scott has relinquished charge at Deepcut. Major W. S. Crosthwait has been transferred from Upper Topa, Murree Hills, to the Military Hospital at Ambala Cantonment. Major H. G. Pinches has arrived home from the Straits Settlements. Major J. H. Barbour has been appointed to the London District. Major E. V. Aylen has taken up duty in the Rawal Pindi Division.

Captain J. McKenzie has been transferred from t Military Hospital at Calcutta to Dinapore Cantonmen Captain E. M. Pennefather has been appointed to t Military Hospital at Multan Cantonment. Captain B. Patch has embarked for India. Captain J. F. Whela has been appointed Deputy Assistant Director of Medica Services, Sanitary Branch, to the Poona Division of th Southern Army in India. Captain E. C. Phelan has joine at Barrackpore Cantonment. Captain H. C. Winckworth ha embarked for a tour of service in India. Captain F. Case ment has been appointed to the Scottish Command Captain R. J. Cahill has been transferred from Athlone t Londonderry. Captain N. Low has joined at Colchester. Captain C. T. V. Benson has been granted leave of absence home from India for six months. Captain W. K. Beamen has been appointed to the Northern Command. Captain L. V. Thurston has been transferred from Bordon to Aldershot. Captain M. Keane has taken up duty at Calicut. Captain E. B. Lathbury has been appointed to the Irish Command. Captain J. A. Renshaw has been transferred from Secunderabad Cantonment to Wellington. Captain C. M. Nichol has joined at Alexandria. Captain J. F. Grant has been appointed Specialist in Electrical Science and Radiography to the Burma Division. Captain P. S. Stewart has been appointed to the Southern Command. Captain R. O. Kelly has been granted six months' leave of absence home from India. Captain F. T. Turner has been transferred to the Home Establishment from India. Captain A. T. Frost has joined at Lucknow Cantonment. Captain J. A. Bennett has been transferred from Newport to the Irish Command. Captain J. W. Houston has been appointed Deputy Assistant Director of Medical Services, Sanitary Branch, to the First (Peshawar) Division of the Northern Army in India. Captain W. Dunn has been appointed Senior Medical Officer, Military Hospital, Thayetmyo Cantonment.

Lieutenant T. E. Osmond has been transferred from Lucknow Cantonment to the Military Hospital at Ambala Cantonment. Lieutenant D. W. Bruce has taken up duty at Rawal Pindi Cantonment. Lieutenant J. Rowe has joined at Deepcut.

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers:—Colonel to be Surgeon-General: Robert William Steele Lyons (dated Jan. 10th, 1914). Lieutenant to be Captain: Thomas Arthur Hughes (dated 30th July, 1913).

The promotion of Major Herbert Henry George Knapp to the rank of Major is antedated from Jan. 29th, 1914, to July 29th, 1913.

The King has approved of the retirement of Lieutenant-Colonel Patrick Percy Kilkelly (dated March 1st, 1914).

Lieutenant-Colonel S. E. Prall, medical officer of health of the Port of Aden, has been granted leave of absence home on medical certificate. Lieutenant-Colonel the Hon. C. Mactaggart, C.I.E., has been appointed to officiate as Inspector-General of Civil Hospitals, Agra and Oudh, *pro tem.* Lieutenant-Colonel E. R. Parry has been appointed to officiate as Superintendent of the Alipore Central Jail. Lieutenant-Colonel A. E. Berry has been appointed Specialist in Ophthalmology to the Fifth (Mhow) Division.

Major A. King has been placed under orders for Bombay. Major W. D. Hayward, medical storekeeper to the Government of Madras, has been granted 20 months' leave of absence. Major J. L. Marjoribanks has been appointed Medical Officer of Health of the Port of Aden and Medical Officer to European General Hospital at Aden. Major T. Hunter has been appointed Civil Surgeon at Naini Tal. Major C. F. Marr has been appointed Medical Storekeeper to the Government of Madras. The services of Major W. G. Richards have been placed temporarily at the disposal of the Government of Madras. Major H. W. Illius has been appointed Civil Surgeon of the Second Class. The services of Major J. E. Clements have been placed permanently at the disposal of the Government of the United Provinces of Agra and Oudh for employment in the Jail Department.

Captain G. L. Duncan has been appointed to hold medical charge of the 90th Punjabi Regiment. Captain R. H. Lee has been appointed Superintendent of the Midnapore Central Jail. Captain W. S. J. Shaw has been appointed Superintendent of the Central Asylum at Yeravda. Captain R. D. Saigol has joined the Civil Medical Department in Burma. Captain C. L. Dunn has been appointed for special duty in connexion with the prevention of plague in the Punjab.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank: George H. Haines, Howell G. Jones, and Henry C. Rook.

Cadet Andrew Robert Fausset Clarke, from the Edinburgh University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated Feb. 17th, 1914).

No. 18 Field Ambulance, Lieutenant-Colonel Fred D. Woolley resigns his commission (dated March 21st, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

4th London Field Ambulance, Royal Army Medical Corps: Lieutenant Herbert E. Middlebrooke resigns his commission (dated April 4th, 1914).

5th London Field Ambulance, Royal Army Medical Corps: John Edward Sandilands (late Captain, List of Sanitary Officers whose services will be available on mobilisation) to be Lieutenant (dated April 4th, 1914).

1st Lowland Field Ambulance, Royal Army Medical Corps: Robert Scott Taylor to be Lieutenant (dated Feb. 19th, 1914).

1st London (City of London) Sanitary Company, Royal Army Medical Corps: Lieutenant Joseph Grounds to be Captain (dated Dec. 4th, 1913).

Sanitary Officers whose services will be available on Mobilisation.—Captain John E. Sandilands resigns his commission (dated April 4th, 1914).

2nd London Clearing Hospital, Royal Army Medical Corps: Lieutenant-Colonel Charles Monk, Retired List (late of the Indian Medical Service), to be Lieutenant-Colonel (dated March 6th, 1914).

For Attachment to Units other than Medical Units.—Ernest Mannering Morris (late Captain, Unattached List for the Territorial Force) to be Lieutenant (dated March 20th, 1914).

Attached to Units other than Medical Units.—Captain William Ritchie is seconded under the conditions of paragraph 114 of the Territorial Force Regulations (dated Feb. 19th, 1914). Captain Arthur H. W. Hunt resigns his commission (dated April 4th, 1914).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Charles Gordon Watson (late Captain, List of Officers attached to Units other than Medical Units) to be Captain (dated Feb. 13th, 1914).

ROYAL NAVAL MEDICAL SERVICE EXAMINATION.

At the examination for appointments as Acting Surgeons for the Royal Naval Medical Service held on March 30th and 31st and April 1st and 2nd, 17 candidates were successful as follows:—

	Marks.
F. C. Hunot, Guy's Hospital	1805
H. B. Parker, London Hospital	1728
R. F. Quinton, London Hospital	1685
J. L. Priston, London Hospital	1665
M. J. Aitken, Glasgow University	1665
J. A. Maxwell, B.A., Trinity College, Dublin	1610
W. G. Thwaytes, Edinburgh University	1555
M. S. Moore, Trinity College, Dublin	1513
W. P. Beattie, Aberdeen University	1470
F. E. Fitzmaurice, University College, Cork	1433
C. E. Greeson, Aberdeen University	1408
T. J. O'Riordan, University College, Cork	1385
J. C. Kelly, Trinity College, Dublin	1375
H. W. Fitzroy-Williams, Victoria University, Manchester	1373
T. Hill, University College, Cork	1343
J. M. Horan, University College, Cork	1295
G. M. Graham, Edinburgh University	1233

The maximum number of marks obtainable is 2400.

THE SESSION AT HASLAR.

On the completion of the course of instruction for the winter entry of Acting Surgeons, Royal Navy, at Haslar, the prizes and commissions were distributed on April 2nd by the Medical Director-General of the Navy, Surgeon-General A. W. May, C.B., K.H.P. The following is a list of the successful candidates with the aggregate marks obtained at the London, Greenwich, and Haslar examinations:—

	Marks.
A. R. Sharrod	3499
J. S. Elliott	3421
A. J. Tonkinson	3420
T. J. Kilbride	3275
J. R. Haldane	3213
J. S. Harvey	3155
J. P. Blockley	3086
W. H. Murray	3052
G. H. Hayes	3036
P. B. Wallis	2964
H. C. A. T. Cannon	2901
H. J. Hopps	2322

The gold medal was gained by Acting-Surgeon A. R. Sharrod, formerly of the London Hospital, and the silver medal by Acting-Surgeon J. S. Elliott, formerly of Edinburgh University. The three Admiralty prizes were respectively gained by Acting-Surgeon A. R. Sharrod, Group I. Haslar subjects; Acting-Surgeon T. J. Kilbride, Group II. Haslar subjects; and Acting-Surgeon A. J. Tonkinson, Greenwich subjects. Special commendations are as follows: Acting-Surgeon A. R. Sharrod, for obtaining highest marks at the Haslar examination, and for being first in the two Haslar groups; and Acting-Surgeons Sharrod, Elliott, and Wallis for zeal and ability shown in the performance of their ward duties. The Director-General, in presenting the prizes and commissions to the surgeons, told them that their duties would have to deal with the physical and moral welfare of the Navy. There was no doubt, he said, that not only the welfare but the very existence of this country depended on the Navy. It was common for people outside the service to imagine that efficiency consisted in the number of ships the country possessed, and to forget that behind the guns and in the ships there was the *personnel*. It was really upon the efficiency of the *personnel* that the power of the navy depended. Their work on shore would not much differ from that of the ordinary hospital work, for naval hospitals were in no way inferior in scientific attainments to the ordinary shore hospitals. Their life on board ship, however, would differ very much from anything they had either seen or contemplated in their life on shore. He thought it would be clear to them that it was their duty to prevent the *personnel* of the fleet from becoming ill rather than to cure men when they were ill, and to remember that they should place as many efficient men in the fighting line as possible. Prevention of illness must therefore be their aim on board ship. Continuing, the Director-General dwelt at some length upon the important question of ship ventilation, and in dealing with preparation for war urged the great importance of instructing the men in rendering first aid to the wounded, and reminded them that they would have to consider such matters as transporting the wounded down from the fighting tops and up from the stokeholds, as well as being prepared to carry out operations under very difficult circumstances.

AT the next meeting of the Society of Medical Officers of Health, which will be held at 5 P.M. on Friday, April 17th, at 1, Upper Montague-street, Russell-square, W.C., a paper will be read by Dr. B. A. Peters, lecturer on infectious diseases, University of Bristol, on the Elimination of Cross Infection in Hospitals. As this is a question affecting all hospitals, and especially those for children, it is hoped that the meeting will be attended by members of the medical staffs of these institutions.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 24 cases were considered and grants amounting to £267 voted to 22 of the applicants. The following is a summary of the cases relieved:—

Widow, aged 75, of M.R.C.S. Eng. Only income 5*s.* per week from Old Age Pension. Health very bad and failing sight. Voted £18.—Widow, aged 62, of M.D. Glasg. After husband's death endeavoured to support herself by taking boarders. In consequence of ill-health and lack of boarders unable to pay her way. Voted £12.—Orphan, aged 63, of M.D. St. And. Takes in paying guests, but illness and bad season cause of distress. Voted £10.—M.D. Q.U.I., aged 80. Private practice diminished and only a few panel patients. Voted £18.—Orphan of M.D. Edin., aged 68. Distress caused through the foreclosure of mortgages on leasehold property. No income at present. Relieved once £12. Voted £12.—Widow of M.D. Glasg., aged 56. Endeavours to earn a little by taking in a boarder. Suffering from chronic rheumatism. Children unable to help. Relieved seven times, £54. Voted £12.—Widow of M.D. Edin., aged 59. Has very indifferent health. Children only able to help slightly. Relieved four times, £44. Voted £12.—Orphan of M.R.C.S. Eng., aged 75. Unable to work in consequence of recent accident and old age. Just been elected an out-pensioner of £26 per annum, and has an annuity of £9 15*s.* 6*d.* Relieved once, £10. Voted £10.—Orphan of M.R.C.S. Eng., aged 65. Endeavours to earn a little by taking in boarders, and just a little assistance from relatives. Cause of present distress, death of mother and sister, both of whom had small annuities. Relieved seven times, £84. Voted £12.—Orphan of M.R.C.S. Eng., aged 66. Income from investments only £20 per annum. Lives with sister whose income also is only £20. Distress caused by loss of investments and ill-health. Relieved twice, £24. Voted £18.—Orphan of M.R.C.S. Eng., aged 59. Has invalid mother to nurse. Mother lost income through building society frauds. A little assistance for invalid comforts from the Guild. Relieved twice, £24. Voted £12.—Orphans of M.R.C.S. Eng., aged 41 and 43. Endeavour to earn a living by letting rooms. Bad season cause of present distress. Relieved once, £10. Voted £10.—Widow of L.R.C.P. Edin., aged 56. Unable to earn anything in consequence of bad health. Receives a little help from the Guild. Relieved eight times, £103. Voted £12.—Orphan of M.R.C.S. Eng., aged 50. Difficulty in obtaining suitable employment through unsatisfactory health. Relieved twice, £27. Voted £12.—Widow of M.D. Glasg., aged 69. Income only £14 per annum allowed by friends and a little help in the winter from the Guild for coal. Health bad. Relieved once, £12. Voted £12.—Orphan of M.R.C.S. Eng., aged 63. Income only £5 per annum from a friend. Has very bad health and quite unable to do anything. Relieved five times, £60. Voted £12.—Orphan of L.R.C.P. Irel., aged 52. Endeavoured to support herself until two years ago, when health broke down. Income £39 per annum from relatives. Relieved once, £10. Voted £10.—Widow of M.R.C.S. Eng., aged 59. Health bad and cataract of left eye and quite blind in right eye. Children quite unable to help. Relieved three times, £30. Voted £10.—Orphan of M.R.C.S. Eng., aged 57. Only able to earn a small sum per week by needlework, and a relative helps to pay the rent. Health bad. Relieved 16 times, £190, and special £5. Voted £12.—Orphan of L.R.C.P. Lond., aged 67. Blindness and nervous breakdown. Only income £17 per annum from a society. Relieved nine time, £90. Voted £12.—Orphan of M.R.C.S. Eng., aged 45. Endeavours to support herself by letting rooms, but has been unsuccessful recently. Relieved three times, £30. Voted £12.—Widow of M.R.C.S. Eng., aged 66. Suffering from malignant growths of the breast. Endeavoured to earn a little by letting room. Children only able to help very slightly. Little help for nourishments from the Guild. Relieved 13 times, £156. Voted £10.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 996.)

XLII.—LONDON: FAVOURABLE VIEWS OF THE ACT.

IT now became my task to call on various practitioners who are on the panel and who approve of the Insurance Act. My first visit was to a popular practitioner living in the Fulham-road, who expressed himself as being quite satisfied. He had some 800 insured persons on his list and paid only about three visits a day. Out of 24 visits paid on the day of my call only two were to panel patients. Some came to his surgery from long distances when they were really too ill to go out, and he had to hasten them home and to bed. Nor did he get the numerous night calls he had feared; but very trivial cases did come to his surgery, people who complained that their corns hurt them or that they had warts. But there were, he said, in Fulham some panel doctors with too long lists. One of them was credited with a list exceeding 4000, and another 2500. Patients had used their right under the Act to put themselves on the list of practitioners whom they desired to see, and thus it was that some insured persons, whom he did not know before, had come to him. Nor had he found that his panel work interfered with his private practice. On the contrary, it had increased the number of his private patients, for now he was attending, and for the usual fees, the dependents of the insured.

It would be a mistake, however, to conclude from the above optimistic view that because a doctor is on the panel and approves, in a general sense, of the Insurance Act, he is therefore quite at ease and quite satisfied. This is far from being the case, for numerous improvements are suggested and many apprehensions entertained.

The Group System.

In quite a different part of the metropolis, in Lewisham, I saw a well-known and popular panel doctor who anticipated the possibility of a State Medical Service as a solution of the problem of medical benefit. In the meanwhile, and though he did not use such terms as collective or coöperative effort, he strongly advocated the organisation of panel work in the "group" form. To him it was wasteful and injurious to turn private dwellings into surgeries. In rural districts, where the population was scattered and practitioners lived several miles away from each other, this could not well be avoided. But in densely populated industrial centres, in London especially, it was a scandalous waste of opportunity and of resources for every panel doctor to keep up a petty little surgery of his own. Panel doctors, he urged, should form groups numbering at least six and preferably more. Jointly these panel doctors should hire a house, or, if it be possible, they should have a building planned and constructed specially for their purpose. Here there would be one large well-appointed waiting room, and as many consulting rooms in communication with the waiting room as there were panel doctors grouped together. Then there would be other rooms for electric treatment, bacteriological examinations, X rays, &c.; and thus jointly many facilities could be secured that no one panel doctor could by himself afford to supply. Above all, there would be the advantage of rendering coöperation between the panel doctors both natural and easy. Incidentally this would tend to reduce the prevalence of malingering, and the panel doctors might secure for themselves much greater freedom by agreeing to deputise for each other. The great object to strive for at present was the abolition of the spirit of competition. Under the capitation system this was rendered much more easy of attainment. Indeed, he went on to say, the Insurance Act has already established a State Medical Service, at least as far as the patient is concerned, if this was not so much so in regard to the doctor. The idea of service to the State had got to take the place of the old notion of competition. The Insurance Act was not intended to facilitate "bottle of medicine practice." It was meant to bring into existence a great educational force. The panel doctor was given an independent position with a comparatively safe income, so that he might teach the ignorant masses that a bottle of medicine will not cure disease. They had to teach sanitation. This could be done better in medical centres, such as might be established by grouping panel doctors together, than in small private surgeries. If a doctor speaking in his own small, ill-ventilated, dingy surgery told his patient he must have exercise and more air, the patient would go away and tell his friends that the doctor was no good because he had given him no medicine. But if such lessons were enforced by several doctors grouped in a centre where an object-lesson of cleanliness and ventilation was given at the same time they would be better appreciated.

Unsuitable Surgeries and Complaints against Panel Doctors.

At present, in this part of the south-east of London, there is a panel doctor who examines his patients in the waiting-room before all the other patients. It is true that this is quite an exceptional case, but nevertheless, and though he has no place to see his patients in private, he has quite a long list of poor people who have selected him as their panel doctor. In other parts of London similar scandalous conditions obtain here and there. A section of the population is so down-trodden—poor, wretched people—so inured to rough treatment, that they do not resent lack of proper accommodation. On several occasions my attention has been drawn to a notorious case of this sort on the Surrey side in a thickly populated district. The question is, How long will it be before these forlorn sections of the poor discover that they are badly treated and that better treatment is within their reach if they will avail themselves of the opportunities the Act gives them? Also, and on the other side, better men will come on to the panel when they see that a competence can be assured them, and this, too, without having to engage in any acute phase of competition against fellow practitioners.

As a member of the Medical Service Sub-Committee formed by the London Insurance Committee, my Lewisham informant explained he was in a position to inform me that the greater number of complaints made against panel doctors came from the poorer districts. This was natural, because it was just in such districts—Hoxton and Bethnal Green, for instance—that the panels were understaffed. The patients who were most apt to complain in all districts, and perhaps more especially in the better class districts, were those whose doctor has not gone on the panel. They had thus been obliged to send for a panel doctor whom they had never seen before; and this sort of compulsion was apt to make them critical. The general complaint was that the doctor did not come quickly enough, especially if asked to call in the afternoon or evening. But it must be remembered that in a crowded neighbourhood a panel doctor with a large list might well be detained in his surgery till ten in the evening.

The Good that Grumbling Does.

All this grumbling, whether justified or not, is probably doing good. The grumblers will help to obtain in time a recognition of the fact that the panel patient is extraordinarily protected by publicity. Therefore in time the Act will give a guarantee of good service, because it is a public service and a controlled service. But for the present, at least in many instances, the control is inefficacious.

As far as his own patients were concerned my informant had but little complaint to make. He had more than 1000 insured persons on his list, and many of them called on him as little as they possibly could. Of course, like all his colleagues, he was annoyed by trivial cases, but he did not find that the working class bothered him in that manner. It was the clerk earning 35*s.* a week who rushed off to the doctor on the slightest provocation. And by the side of the trivial cases he had work of the greatest scientific interest. He had one obscure case in particular which he would gladly have gone from one end of London to the other to see.

Improved Conditions of Practice under the Act.

I inquired at this point whether the Insurance Act could be utilised to check the spread of venereal disease. The reply was that so many practitioners stood in terror of the "unco' guid" that they dared not advise as to what precautionary or prophylactic measures, other than moral restraint, could be taken. But the Act would be, he maintained, a powerful instrument for the general prevention of sickness. When things had had time to settle down panel doctors would be less timid; they would think less and less about losing patients. A conscientious doctor would not lose more than a patient here and there, and under the capitation system this amounted to a very small sum. It did not affect seriously the much greater security of income now enjoyed. Of course, under the contract system there was a danger that some practitioners might drift into a groove, finding little to encourage them to improve their methods, and resting content to rub along in the easiest way. Would the glare of publicity be sufficient to prevent such neglect, or would the State institute compulsory post-graduate courses so that medical men in its service might be forced to keep abreast with the march of science?

Then there was also the question of private practice. In the case of this informant again the going on to the panel had not interfered in the least with his private practice. On the contrary, insured persons on his list had, on several occasions, introduced him to private patients. His private practice had so increased, and his position was so much improved after working for one year on the panel, that he had just been able to exchange his bicycle for a new motor-car. Taking everything together, the outlook seemed encouraging to him. There was difficulty in some parts of London. Even before the Act there were not doctors enough in certain districts; now it should be easier to induce practitioners to settle in those districts. When all the advantages were better known, a better supply of doctors would follow. But such a sweeping change as that brought about by the Insurance Act required several years to produce its full effects. Such, at any rate, were the principal opinions and impressions that were set before me by friends of the panel system during my visit to Lewisham.

(*To be continued.*)

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

The Studebaker Two-seater Cabriolet.

To many people an American car denotes a cheap one which perhaps goes well and climbs hills excellently, but probably not for long. In fact, recently, when discussing with a colleague the purchase of such a car, he said: "They are like some razors: not made to shave, only to sell." As a consequence of this and other conversations and inquiries, and also because the car in question seemed to possess qualities that adapted it well to the needs of a doctor, I spent a day in thoroughly examining and testing a Studebaker cabriolet, concerning which I see that a correspondent of THE LANCET has recently made inquiries.[1] The cylinders are cast *en bloc*, and have a bore of 3½ inches and a stroke of 5 inches. The valves are all on the left side, and are enclosed by a plate which is accessible and easily removable. The valves themselves are drop-forged with their stems electrically welded to the head. The operating push-rods are adjustable. The pistons are of grey iron with polished heads, and are fitted with three piston rings above the gudgeon pin. The connecting rods are of drop-forged steel. The gudgeon pin bearing is of phosphor bronze. The big ends are lined with cast babbitt metal, and packing pieces are provided for adjustment. The crank shaft is of chrome nickel steel, and all the bearing surfaces are ground to micrometrical exactness. Lubrication is by means of a plunger pump driven direct from the cam-shaft. A supply of oil is carried in a sump in the bottom of the crank case, and from here the pump forces it into four troughs, one under each connecting-rod. There is also a sight gauge-glass on the dashboard, from which oil is led to the timing gears at the front of the engine. This gauge serves as an indication that the pump is working correctly. An oil-level indicator fitted to the side of the crank case, which is easily visible, shows accurately at all times the quantity of oil in the sump. Ignition is by means of a single coil mounted on the off-side of the engine, and the current is derived from accumulators which are kept fully charged by the dynamo, and these also supply current for the lamps and the engine-starting electric motor. A dry battery is connected to the ignition coil as a standby in case of derangement of the main system. Cooling is by means of a gilled tube radiator with a fan behind it, and a large centrifugal pump. The carburetter is a Schebler, and a regulator is placed on the dashboard enabling the adjustment of the air supply to be varied according to climatic conditions. The clutch is a leather-faced cone, which, as a matter of fact, is probably as simple and as satisfactory as any. Flat steel springs are fitted underneath the leather to facilitate easy engagement. The transmission is by propeller shaft with two efficient universal joints. Three forward speeds and one reverse are provided, all operated by a single lever on the gate change system. The housing of the rear axle also contains the gearbox. The control is by throttle and spark levers on the top of the steering wheel, with a foot accelerator situated between the clutch and foot brake pedals. The brakes all act on the rear hubs—one set being by external contracting lined steel bands acting on steel drums, whilst the other set is by internal expanding shoes acting on the same drums. The electric self-starter is fitted on the off-side of the engine, and is connected, by means of a suitable reduction gear and chain, to a chain sprocket and roller clutch fitted on the front end of the crank-shaft. The starting motor and the chain are stationary, except when in use for the actual purpose of starting the engine.

---

[1] THE LANCET, April 4th, p. 1014.

I had no doubt that the car would go, but I wanted evidence. I therefore suggested to the representative of the company that I help myself from their store to various parts for examination as to quality and machining. They agreed with pleasure. I found their depôt a perfect hive of industry, some hundreds of cars being in various stages of preparation for delivery. Here I saw the tuning-up and testing of the products of the firm. It is in the thoroughness with which this is done that the difference exists between the best and the mediocre car—at least, from the user's point of view. The tester represents, or should represent, an aggressive, expert and discontented purchaser. At the depôt each detail is separately considered, so that the car leaves with its engine up to standard power, quiet and fast on the level, cool in traffic and on speed, and with the carburetter consuming a minimum amount of petrol. In the store I picked out a differential star, four different spider pinions, a connecting rod, the two parts of a gearbox through shaft, each from different piles, some gear pinions, a shackle pin, cam-shaft, and one of the universal joints. These I took with me to Woolwich, where I examined them with an engineering friend. His opinion was that the material was good and the machining excellent, and though in unimportant parts the pieces were rough the bearing surface and important parts were well finished and undoubtedly, as stated by the makers, ground to micrometrical exactness. All the spider pinions, though picked out indiscriminately from a stack of many hundreds, were a perfect fit on the star. The through shaft parts were also a good fit, the bush for the bearing between the two fitting perfectly; the connexion between the two portions is by a three-point dog clutch. Some might prefer an internal tooth pinion, but on many cars this method is adopted, and it is quite an accepted practice. From Woolwich I took the car and tested it over some Kentish hills. I found the engine starter worked well, the engine gave all the power necessary, and that without noise or fuss of any kind; the springing was good, and even over rough roads there was little hopping or swerving, but of course a shock absorber would have been an improvement. Although three speeds are provided, they are requisite only for starting and for steep climbs. As a rule, from a crawl to well over the legal limit, the top speed obtained all the time. In traffic the control was excellent, and of this I had proof in Piccadilly and over that unpleasant crossing, the Elephant and Castle. The gear changing is easy, and immediately on taking the steering wheel and opening the throttle the sweetness with which the clutch takes up the drive was noted. The way, too, the car travelled up a hill on top gear made driving a pleasure. The brakes were tested in both directions on a hill of 1 in 4·8, and gave ample proof that either is sufficient for any emergency. The car is comfortable to drive, and clutch, brake, and throttle pedals are well situated, though personally I prefer the latter on the left instead of between the two former. The body is comfortable, the upholstering good, and entry can be made on either side.

There is little doubt that this car will become popular with the medical profession, especially as, considering the quality, the price is reasonable.

Motor Engineering Pupils and Scholarships.

The Daimler Company, Limited, of Coventry, have sent to all the technical schools and colleges throughout the United Kingdom inviting pupils in their works. Their scheme seems to be a very comprehensive one, and planned on broad and generous lines. It is necessary for candidates to show evidence of some scientific training. Under their new system it is possible for a pupil to win a scholarship if his work reaches a sufficiently high standard.

The Rapid Valve Truer.

There is no question that the efficiency of an internal combustion engine is largely dependent on its compression, and therefore any leakage past the valves reduces this efficiency. As a rule, grinding-in suffices to make a valve "bed" correctly on its seat. As a matter of fact, a large number of owner-drivers are rather too keen on grinding-in their valves, but the minority who postpone this procedure too long may find that the badly worn valve face requires an enormous amount of grinding, and may even call for the aid of a lathe. It is in these cases that the rapid valve truer will be found useful. The instrument consists of a cutter screwed into a casing, which latter has inside it a double-coned part and a single-coned part, forming ball races for two sets of balls. These hold the valve stem concentrically true with the cutter, so that the valve face beds evenly when being trued up. The cones are adjustable, and one cutter will true a large number of valves. The method is simple. When the instrument was tested by the writer on a ten-year-old badly pitted valve found on a scrap heap the resulting finish was equal to that obtained on a lathe with skilled workmanship. The device is sold by Messrs. Brown Bros., Limited, of Great Eastern-street, London.

Boilerine Radiator Tablets.

We have submitted these tablets to laboratory examination and find that the claims made in regard to their property of preventing lime deposit or of dissolving it when formed are substantiated. By their use the water in the radiator, and therefore the tubes, are kept clean, the circulation is unimpeded, the radiation is maintained at a maximum, and the risk of choking the channels avoided. Analysis disclosed the ingredients which have no corrosive action on metal when used in the quantity directed, which is, of course, based upon the degree of hardness of the water. For London water two tablets to the gallon are sufficient. A soluble combination of the lime salts of the water with the ingredients of the tablet is formed which has negative properties in regard to metal. The makers are Messrs. Boilerine, Limited, 885A to 897, Old Kent-road, London, S.E.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

MANCHESTER.

The Ways of Women Inebriates.

IN the annual report of the Lancashire Inebriates Reformatory at Langho, near Blackburn, Dr. F. A. Gill, the medical superintendent, states that 60 per cent. of all committed were mentally defective. Commenting upon the traits of women inebriates, he thinks the chief features of this class are defective intelligence, quarrelsome disposition, perverted or absent moral sense, and lack of control over impulses. Defective intelligence is expressed chiefly by a condition of general apathy, lack of energy, faulty memory, and little power of thought or judgment. "Their sense of honour," he says, "is simply non-existent. A lie is a matter of convenience, truth or untruth is a matter of indifference so long as it will enable them to attain their ends. Morality has no meaning. ...... Some of them nearly live a bovine existence, eating, dodging their work, and not infrequently falling asleep over such work as they do. When punished by confinement to cells they are perfectly content to do absolutely nothing."

Diseases in Infancy and Childhood: Boiling of Milk and Tuberculosis.

Dr. Ralph Vincent gave recently an address to the Manchester Sanitary Association on the prevalence of disease amongst babies and young children, in which he said that many of the diseases of children, including tuberculosis, were caused or led up to by inadequate or improper food. He did not think there was much, he said, in the cry about the ignorance of mothers. The great cause of the prevalence of disease in the young was the absence of food adequate for the requirements of the infant. Mothers should be encouraged to breast-feed their infants, as milk was not in its natural condition when it was boiled. He repeated the view that boiling destroyed a vital property of milk, and declared himself able to exclude cow's milk as a cause of tuberculosis in a great majority of cases.

Obsolete School Buildings.

Lord Sheffield on April 3rd, as President of the Manchester and Salford District Education Association, referred to the large number of defective school buildings in Manchester and Salford. According to reliable statements there are far more than a score of schools with an average daily attendance of 20,000 children which are utterly unsuitable for their purpose, and which have been repeatedly pronounced to be defective by the Board of Education. Most of these were built before the Education Act of 1870. Since then there has been a complete reformation in the construction, lighting, and other hygienic requirements of school buildings.

Charitable Bequests.

Miss Elizabeth Catherine Wagstaffe, of Cheetham Hill, Manchester, among other legacies, bequeathed £300 to the Clinical Hospital, Manchester; £500 to the Salford Royal Hospital; and £500 to the Cancer Pavilion, Manchester.

April 7th.

BRISTOL AND WESTERN COUNTIES.

Farm Colony for the Feeble-minded.

A SHORT time ago Mr. H. H. Wills offered a farm, worth about £7000, at Bishop's Lydeard, near Taunton, for use as a farm colony for the feeble-minded of Bristol and Somerset, on condition that the sum of £14,000, for the erection of buildings, was collected by March 20th. There is still a deficit of £4000, but Mr. Wills has extended his time limit to May 31st, so that the necessary sum may be raised if possible. A series of meetings is to be arranged to make the need of such an institution more widely known. It is hoped that the cost of upkeep will be largely covered by grants from local governing bodies and by the produce of the farm itself.

The Late Surgeon-Lieutenant-Colonel Smith.

The death of Surgeon-Lieutenant-Colonel Samuel Smith, in his seventy-ninth year, removes a familiar figure from the streets of Bristol. He had been in practice here for many years, and for a considerable time held the office of battalion surgeon to the 1st Gloucester Volunteer Royal Engineers, also receiving a commission in the Army Medical Reserve. After 23 years' service he retired with the Victorian Decoration and permission to retain the rank and to wear the uniform of Surgeon-Lieutenant-Colonel. He was a Fellow of the Royal Meteorological Society and of other learned societies. In spite of his advanced age he was very active, and remained in practice until the onset of his last illness.

Consulting Medical and Surgical Officers to the Bristol Poor-law Institutions.

The Bristol board of guardians has decided to follow the example of other large cities by appointing a physician and a surgeon respectively, at a salary of £100 a year each, to act in a consultative capacity to its workhouses and infirmaries. The conditions of service have not yet been definitely stated, and the appointments have yet to be advertised; but there is little doubt that if the details are satisfactorily arranged these posts will add greatly to the efficiency of the local Poor-law medical service.

Hospital Sunday Fund at Bristol.

At present the sum of £1959 has been received in connexion with the Lord Mayor of Bristol's Hospital Sunday Fund. This is slightly in excess of the total for 1913, which amounted to £1957, and as there are still over 30 collections to be sent in it is anticipated that this year's total will exceed £2000.

Bristol Board of Guardians.

The Bristol board of guardians at its meeting last week appointed Mr. R. H. Norgate, L.R.C.P. Lond., M.R.C.S., to be the medical superintendent of the new workhouse infirmary at Southmead, at a salary of £400 per annum. Mr. Norgate has been resident medical officer of the Stapleton workhouse infirmary of the Bristol union for the past 19 years. The guardians also decided to appoint two assistant medical officers.

The Local Government Board and Whole-time Medical Officers of Health.

The Local Government Board recently suggested to the Taunton rural district council and to the Wellington urban council that owing to the resignations of their respective medical officers of health they should combine and appoint a whole-time officer to the post. Last week these authorities, together with representatives of the Taunton board of guardians, discussed the matter fully, and eventually resolved unanimously to recommend the appointment of a whole-time medical officer who should act as medical officer for the St. James's district of Taunton, medical officer of health for the Taunton rural district and the Wellington urban district, and hold also the posts of medical officer to the Taunton Isolation Hospital and the Children's Homes at Taunton. The salary to be £450 per annum.

A Medical Certificate at Plymouth.

At the Plymouth county court on March 20th, before his honour Judge Lush-Wilson, K.C., a man was summoned for non-payment of rent. The defendant suffered from pulmonary tuberculosis, and his wife produced a medical certificate to the effect that he was unable to work through illness. The practitioner who gave the certificate stated that he had put no date on it. His honour said it was a sad case, but the woman appeared to have put a date upon a certificate which had been previously given to her husband so as to make it suitable for the present case, and to have sworn that her husband was ill in bed, although he was then at work at the dockyard. His honour said that he must lay the facts before the Public Prosecutor and leave him to decide upon the course to be adopted.

April 7th.

IRELAND.

Medical Officers of Health in Ireland.

IN answer to a question in the House of Commons last week, Mr. Birrell, Chief Secretary for Ireland, stated that there were 903 medical officers of health, including medical superintendent officers of health and consulting sanitary officers, employed by local authorities in Ireland. Of these, two were full-time officers, and they were paid salaries of £500 a year or over. Mr. Birrell's answer is inaccurate, as there is only one whole-time medical officer of health in Ireland, the medical officer of Belfast. The information would have been more complete if Mr. Birrell had added that the salary of a medical officer of health in Ireland varies from £5 to £25 a year. THE LANCET recently (March 28th, 1914, p. 924) gave particulars of the obstructions put by the responsible Government department in the way of a local authority which wished to make the office of medical officer of health effective.

Royal College of Physicians of Ireland.

At the meeting of President and Fellows last week Sir Arthur Chance, F.R.C.S. Irel., was elected an Honorary Fellow of the College. The honour is a recognition of gratitude to Sir Arthur Chance for his services to the College while representative of the sister College on the General Medical Council. Sir Arthur Chance is a past President of the Royal College of Surgeons in Ireland, and is surgeon to the Mater Misericordiæ Hospital. At the same meeting Dr. Bethel A. H. Solomons was elected a Fellow.

High Mortality in Dublin.

The death-rate of Dublin has been abnormally high during the past few weeks, even for Dublin.

Scarlet Fever in Belfast.

The scarlet fever epidemic—which has now raged in Belfast since October, 1909—is slowly wearing itself out, for the report of the health of the city during the period between Feb. 15th and March 14th, presented at a meeting of the city council held on April 1st, shows that 132 cases were notified.

A Rise in Salary.

The salary of the medical officer of health of Belfast has been raised from £800 to £900 by two annual increments.

The National Insurance Act in Belfast.

At a meeting of the Belfast Trades Council on April 2nd a resolution was unanimously passed expressing the opinion that the present panel system of obtaining medical certificates has proved a complete failure both in regard to the interests of the insured persons and of the Approved Societies, and calling upon the Chancellor of the Exchequer and the Irish Insurance Commissioners to institute a State Medical Service for the insured persons, failing which a State Medical Service should be initiated for the purpose of issuing medical certificates to insured persons when ill. At a meeting of the Belfast Local Medical Committee held on March 31st Mr. R. J. Johnstone was elected chairman, in place of Sir John Byers, who, through pressure of work, has been obliged to resign. A resolution was unanimously passed thanking Sir John Byers for his services, and deeply regretting his inability to continue in office.

The late Colonel Frederick S. Heuston, A.M.S.

I regret to announce the death of Lieutenant-Colonel F. S. Heuston, at Greystones, co. Wicklow. He had a distinguished career in the Army Medical Service, from which he retired two years ago. A Tipperary man by birth, he received his medical education at the Carmichael school in Dublin, and took the Fellowship of the Royal College of Surgeons. He entered the army in 1884, and saw much active service, beginning with the Black Mountain Expedition in 1888. In 1894 he was seconded for service with the Chinese Government, and took part in the opening of the Imperial Medical College at Tientsin, of which he was for some time president. He served in the Chino-Japanese war, and was decorated by the Chinese Emperor, while he was also a C.M.G. In the South African war he was twice mentioned in dispatches. In his younger days Heuston played for the Irish International Rugby team in three successive years, 1881, 1882, and 1883. He was a brother of Mr. Francis T. Heuston, surgeon to the Adelaide Hospital, Dublin, to whom the sympathy of the profession will be extended.

April 7th.

PARIS.

The Proper Hours for Meals.

Professor Bergonié, of Bordeaux, has invented an electric bed in which the passage of the current through the body of the subject sets up organic combustions similar to those brought on by muscular exercise and leads to reduction of obesity. Professor d'Arsonval has recently communicated to the Académie des Sciences the results of M. Bergonié's studies by means thereof on the energy of the organism. By studying closely the hourly variations of energy in a subject whose mode of life is known and regular and whose weight is constant at the same hours, it becomes possible to construct a curve of the needs of energy of the subject for every hour. It is known that 80 per cent. of the energy is taken up in maintaining the body heat, and that the calls on this energy for heat production are in inverse proportion to the temperature of the surrounding medium. In civilisation, where activity is prolonged far beyond sundown and for a part of the night, the draught upon energy at these hours is considerable. On the other hand, between 10 P.M. and 6 A.M., during sleep, the heat demand is *nil*, and energy is stored afresh for use with great intensity on waking. M. Bergonié concludes that the hours at which it is suitable to take into the system by means of food the sources of this energy must be regulated by these considerations; but it is necessary to take note of the period that elapses between the time of taking food and that at which its digestion and assimilation have set free all the utilisable energy, just as in the electrical power house the engineer must calculate the time that elapses between the coaling of the fire and the augmentation of the voltage in the circuit. M. Bergonié has discovered that the least suitable hours for meals are between noon and 1 P.M. and between 7 and 8 P.M.—that is to say, precisely those hours which in Europe modern usage has set apart to meals. It is true that these meal hours have varied considerably down the ages, and that in the last century they were earlier than at present. According to M. Bergonié the meal hours that a rational hygiene would prescribe would be as follows: the principal meal of the day should be taken at 7.30 A.M. or as soon after as possible, so as to obtain all the necessary energy for the day's work and to restore the liver, emptied by the night's abstinence. A second meal of 300 to 400 calories, for which a luncheon of milk, sugar, and cakes would suffice, should be taken about 4 P.M. Finally, a third light repast of 700 to 800 calories at 8.30 or 9 P.M. would complete the alimentary *régime*. M. Bergonié adds that in a family which has accepted his views this *régime* has been followed for six years, and has furnished excellent results as regards the general health of all the members. These views have aroused much surprise in France; in England it would be necessary, in conforming with this *régime*, to have breakfast a little earlier and of the old-fashioned solid sort, to reduce luncheon to a sort of tea, and to postpone and reduce the evening meal.

Amœbic Dysentery in France.

A communication by Professor Landouzy to the Académie de Médecine suggests that there is a gradual acclimatisation of amœbic dysentery in France. Already 14 cases are known in persons who have never been out of France, and among these have occurred seven hepatic abscesses and five deaths. Four of the victims had associated with colonials in France and appear to have been directly infected, but the others had had no such exposure. Professor Landouzy reported the case of a mariner at the Hôpital Laennec, aged 38, who had always served on boats plying in the north of France. There was no suspicion of dysentery. The patient was cachectic, with an enlarged liver, and had suffered for months from vomiting and diarrhœa (not bloody). Chemical reagents showed a feeble hæmoglobin reaction however. Hepatic cancer was diagnosed, but at the necropsy made 24 hours after death an enormous hepatic abscess was discovered with the characteristic intestinal ulcerations of dysentery, both abscess and ulcerations showing amœbæ. Inoculation into a cat proved negative. Professor Landouzy reported another case, that of a man who had spent a year in Morocco and returned without any sign of dysentery, though he had lost flesh and was easily fatigued. A little later he sustained in an automobile accident a severe contusion of the liver, and three months afterwards a sharp febrile attack with a large abscess of the liver containing amœbæ ensued. This man was an unwitting germ carrier. From these observations Professor Landouzy presages an indigenous amœbiasis which is gradually becoming acclimatised and is giving rise to numerous germ carriers, in whom the disease may break out on the occasion of a traumatism, and who especially may be unconscious and unrecognised conveyers of it. The special danger is that the medical man is apt to think of dysentery only in connexion with patients returned from the colonies. Professor Landouzy suggests that special search be made for the amœba in all cases of rebellious diarrhœa of unexplained origin and accompanied by cachexia, even though there may be no blood in the stools and no hepatic symptoms. Moreover, returned colonials who have attacks of dysentery must no longer be regarded as incapable of spreading the disease, but the same precautions as are used in the colonies must be rigorously insisted on in their case. M. Vaillard, president of the Conseil Supérieur de Santé de l'Armée, while admitting the possibility of contagion through returned colonials, protested against exaggerated fears. Although the numbers of returned soldiers and civilians during the past 30 years had greatly increased, the number of cases had not increased, and the discovery of a really specific remedy in emetine now rendered possible the sure sterilisation of such cases. In this view he was supported by M. Bertrand, director of the Service de Santé of the Navy.

Hospital Sanitation.

Considerable attention has been directed to a recent article in the *Presse Médicale* by Dr. Raoul Brunon, physician to the General Hospital at Rouen and director of the medical school there. He alludes to the millions spent in Paris by the Assistance Publique for the construction of new hospitals, no expense having been spared in making them comfortable to the verge of luxury, and insists that no improvement in hospital statistics can be looked for unless regulations such as those which have sufficed to render the oldest hospital buildings sanitary are adopted generally. These necessary conditions are adequate floor space for the beds, continuous ventilation of the wards, and the necessary minute personal attention to each patient many times a day. Even the newer hospitals, if lack of room causes overcrowding, too close proximity of beds, and insufficient air space, or if a deficiency in the *personnel* precludes the proper washing of individual patients and the daily disinfection of the floors, walls, and furniture, will show statistics as unsatisfactory as those of the older buildings. When a town undertakes the construction of costly hospitals they cannot for the same expenditure provide the same number of beds for the community. Overcrowding soon occurs and with it insanitary conditions. In an old hospital if the walls and floors are washed every day, if the wards are frequently emptied and disinfected and are always properly ventilated, there will be less infectiousness present. M. Brunon instances the hospital mortality from broncho-pneumonia in whooping-cough and measles as due to contagion of the hospital wards. In the old General Hospital of Rouen, under his direction, not a single case of death has occurred from measles or whooping-cough for many years, thanks to rigorous asepsis and ventilation, while at Paris the mortality from measles is still severe. In 1887 the mortality from measles exceeded 40 per cent. at Paris, in 1898 the mortality was such that the Chef de Service demanded the closing of the whooping-cough wards after 103 children had died therein in ten months. In 1899 the mortality from broncho-pneumonia after measles was still about 30 per cent. It is to-day 14 per cent. at the Enfantes Malades, 12 per cent. at the Trousseau, and 9 per cent. at the Hôpital des Enfantes Assistés.

April 6th.

VIENNA.

Professor Wenkebach appointed Successor to Professor von Noorden.

Professor Frederick Wenkebach, the director of the medical clinic of Strassburg, having been invited by the Austrian Ministry of Education to become the successor of Professor von Noorden in the first medical clinic of Vienna, has accepted the offer thus made to him. As already mentioned in one of my letters, Professor von Noorden was induced by reasons of a personal nature to resign his post and to relinquish his clinic, a first-rate and completely modern institute. Professor von Noorden has founded in Vienna an excellent institute for the investigation of the processes of metabolism, and his successor, who is 50 years of age, and a Dutchman by birth, has done a great deal of work in this direction, so that the departure of Professor von Noorden will be compensated to some extent. Professor von Wenkebach will take over the clinic in the month of May in the coming summer term. He was recommended by the senate of the university "*primo et unico loco*," an honour accorded only to very few professors.

The Winter Term of the Austrian Universities.

Last winter the Austrian universities were very well attended by students, and in particular the medical and biological institutes could not accommodate all those who sought admission. It seems that apart from the natural increase of population the attraction of scientific study induces constantly increasing numbers of young persons of both sexes to betake themselves to some university. The proportion of medical students to those of the other faculties — namely, philosophy, law, and theology—has increased from 19 per cent. to 24 per cent., as compared with the numbers recorded in the winter of 1912-13, whilst the total number of students has gone up by 3 per cent. There were 370 graduations as doctor of medicine in Vienna, or more than 20 per cent. in excess of the graduations last year. The chief increase of students and medical graduates was noted in Vienna and Prague, whilst the other smaller universities had a considerably less percentage. It is interesting to find that the number of foreign students and medical graduates—working in the medical institutes chiefly—is constantly rising, and that the influx comes chiefly from England and the United States of America, whilst the Russian and Italian contingents are rather less numerous than in previous years.

Grievances of Veterinary Students in Vienna.

More than a year ago the relations between the students of the veterinary school and the military managing board began to be strained, but a settlement of the disputed questions was eventually arrived at, although not without much difficulty. Quite recently, however, discord has again arisen, on account of the military authorities in command of the veterinary school having violated the university rules as understood by the students. The authorities having ordered a class to be formed for men who were said to have no right to attend the university, the students regarded this as a serious affront offered to them and demanded satisfaction. When this was refused they not only declined to do their class work but also prevented the delivery of any lectures, the newly-formed class above mentioned being interrupted in like manner with the others. The students demanded the immediate dismissal of the offending officer, and as this was similarly refused the managing board found no way out of the difficulty but to close the school and send the students home without having passed the necessary examinations. This means that the students lose this winter term, and many of them lose also the scholarships and privileges which can be gained only by those who have passed certain examinations. The students of the other faculties in Vienna have expressed their sympathy with the veterinary students in the conflict on which they have entered, and the former in their turn intend taking radical measures to ensure that academic rules and academic liberty shall be respected in all departments of university training.

CANADA.

Medical Inspection of Schools in Quebec and Ontario.

IN Montreal medical inspection of schools is under the Board of Health. Up to the present time the city has been divided into 19 districts, with a medical inspector in charge of each on part time at $1400 salary per annum. There are 254 schools in the city with approximately 85,000 pupils, so that each inspector is in charge of some 13 schools. There have been only seven nurses, but with the reorganisation of the Health Department of the city now proceeding under the new medical officer of health, Dr. Boucher, this number will be increased to 15 or more. The medical inspectors will probably be called upon to give all their time to this work on increased remuneration. Since medical inspection was established pediculosis and scabies have almost disappeared from the Montreal schools. Practically all the population of the city is vaccinated. The people coöperate willingly in medical inspection. Outside of Toronto, which has a well-established system under the Board of Health, a number of places in Ontario have inaugurated this work. Several other cities and towns have considered the question, but are waiting for a provincial law establishing medical inspection throughout the province.

Ontario Workmen's Compensation Bill.

In 1910 the Ontario Government appointed Chief Justice Sir W. R. Meredith Commissioner as to the laws relating to the liability of employers to compensate employees for injuries received during employment. The Commissioner visited England, Germany, and certain places in the United States, and as a result of his studies and observations a Bill is now before the Ontario Legislature which will be passed at the present sitting of that body. It is, however, not satisfactory to the medical profession. When it was first learned that a Commissioner had been appointed the Academy of Medicine, Toronto, appointed a special committee to watch the legislation which might be introduced. This committee was placed in charge of Dr. Bruce L. Riordan; and at a recent special meeting of the Academy Dr. Riordan presented the report of his committee. The Act is to be administered under the powers of a Commission whose decision in all matters shall be final, and there shall be no appeals allowed to the ordinary courts of the province. The committee calls for the reasonable payment of medical expenses in connexion with injuries which is not provided for in the Bill, and points out where the Bill should be amended so as to comply with this fair stipulation. The Bill is based more upon the German than on the British law. The Minister in charge of the Bill has been interviewed by members of Dr. Riordan's committee, who pointed out that coöperation on the part of the medical profession was most vital for the success of the Bill. Due consideration of the points raised by the medical deputation has been promised by the Government.

Syphilis in Toronto.

Quite recently the subject of syphilis in Toronto was under discussion by the Academy of Medicine. Dr. J. S. Graham reported that the total number of cases admitted to the Toronto General Hospital from August 11th to Dec. 13th, 1913, was 412; and of this number 180 gave a positive Wassermann reaction. Professional classes had the low percentage of 7, while business classes stood at 23. Dr. Mann gave the results of tests at St. Michael's Hospital. Of 158 men and 180 women examined, 57·5 per cent. of the men gave a positive reaction, 37·25 per cent. negative, the residue being doubtful. Of the women, 64·5 per cent. gave a positive, and 21·6 negative. Dr. Gordon Bates and Dr. G. S. Strathy tabulated their experiences as revealed by doing the test on about 1200 patients. They dealt with these under the heads: (1) Venereally infected; (2) infected through marriage; (3) inheritance. In the last class the cases were taken from the Hospital for Sick Children, Toronto, and the Hospital for Feeble-minded, Orillia. At the Children's Hospital they tested and found positive the parents of 37 suspected syphilitic children. At Orillia they tested 100 patients. Three were positive. Thirty defective children were also tested at the Children's Hospital; none gave a positive reaction. They come to the conclusion that syphilis plays but a small part in the direct etiology of feeble-mindedness.

Hospital Resignations.

Dr. Francis J. Shepherd, for 31 years senior surgeon of the Montreal General Hospital, has resigned, and is at present on a trip to Panama. Dr. W. H. Hattie, who has been superintendent of the Nova Scotia Hospital for the Insane for 14 years, has resigned, and has been appointed chief health officer for the province.

The Laurentian Society.

This society for the treatment and control of tuberculosis, during the first five years of its existence, has discharged 170 patients from its sanatorium. Of these, 98 are well and following some occupation, 24 are dead, 3 could not be traced, and 45 are still invalids.

March 24th.

INDIA.

The Town Planning of Delhi.

IN considering the future of Imperial Delhi it is important not to overlook the measures required to bring the Delhi of to-day into line with the new capital. The walled city and densely populated suburbs have long had an evil reputation for unhealthiness. Sanitation on modern lines has never been undertaken on a large scale, and epidemic disease in the shape of fever, cholera, and small-pox has levied a heavy toll on the inhabitants. Hence the death-rate has always been high and the infant mortality is even now appalling. For the new city that is being planned to the south to have in its immediate neighbourhood insanitary areas holding a congested population would be a grave mistake. Imperial Delhi in its true sense must embrace all the units that are at present roughly grouped together, and each one must be above reproach in the matter of public health. Improvements, then, in Delhi as we know it now must go hand-in-hand with the Imperial scheme that has for its object the creation of a brand new city on the southern site. Major H. C. Beadon, Deputy Commissioner, in his capacity of president of the municipality, drew attention to this point in his remarks on the annual municipal report for 1912-13. "The most pressing need of the Delhi citizen," he wrote, "is room to build, room to work, room to play, room to walk, room to drive—Room." He showed how the city is hemmed in by the Jumna, the notified area (which includes the civil station), graveyards, railways, and State lands—those to the south being now mainly reserved for the new city. "Instead of decent orderly expansion the people have been huddled into a totally insufficient area, so that the streets have been encroached on, slums have been built, and land has become so valuable that capitalists cannot build, and improvements, however pressing, cannot be effected." He urged very strongly that to relieve this congestion the whole area from the great Indian Peninsular Railway to the Darhaulia Nallah should be town-planned.

Medical Provision in Burma.

The Burma Chamber of Commerce recently called the attention of the local government to the inadequate provision of European medical officers in the province, which was aggravated by the medical policy laid down in the Secretary of State's despatch of December, 1908. In other Indian provinces with an organised European medical service the practice of Western medicine has been encouraged. Here there is no material for the recruitment of a native independent medical service. As examples of the Government medical policy, the chamber points to the refusal to supply Indian Medical Service officers to the growing trade centres, under-staffing the Rangoon General Hospital, and the slow development of the Burma Medical School. It is contended that by the refusal to meet the need for medical aid in rapidly growing commercial towns many valuable lives are lost and commerce has been checked. The policy of repression of the Indian Medical Service is detrimental to the commercial progress of this young province. The local government replied sympathising with the view that it was desirable to post Indian Medical Service officers as civil surgeons in a number of districts for which they are not now available. The need for more such officers in Burma has been represented to the Government of India.

Unhygienic Bombay.

Bombay has been so long known to the countries of the West and to the tourist as "Bombay the Beautiful" that people have not given much thought to Bombay the "unhygienic." It must be regretfully admitted that notwithstanding the very large annual expenditure on its health department, Bombay is still a good deal backward in sanitation. Bombay may be considered as one of the most densely crowded cities in the world. Not only have all available building areas in the city been long since taken up for building purposes, but a very large number of residential quarters in the shape of tall houses and rickety tenements have been allowed to crowd on them without much heed to the needs of the people. There are very few open-air spaces in the shape of parks, gardens, or other places of public resort to act as "lungs" to the city, to the urgent needs of its teeming population, densely packed in every nook and corner of it. What is actually meant by "overcrowded" can only be realised by a nocturnal visit to one or two of the many Goanese residential clubs which exist, or to one of the large tenements in some of the most crowded parts of the city. Most of these tenements consist of very small rooms, ill-ventilated, damp, and unwholesome, and are literally crowded with people, many of whom go out for work during the greater part of the day, and who on return home can scarcely get more breathing space than what is obtainable in the shape of the barest sleeping accommodation at night. No wonder overcrowding should thus stand far and away as one of the largest factors, if not quite the largest, in the very high rate of disease and death in the city. A still greater menace to the health of the city are the perverse and uncleanly habits and the apathy and ignorance of the vast bulk of the people who make up this heterogeneous mass of humanity. Although these things may not be easily preventable all at once, yet there is ample room for the exercise of certain corrective and educating influences, leading gradually up to considerable improvement.

The Calcutta School of Tropical Medicine.

The Governor of Bengal, Lord Carmichael, on Feb. 24th laid the foundation stone of the School of Tropical Medicine at Calcutta. In the presence of a large gathering His Excellency and Lady Carmichael were received by Colonel G. F. A. Harris, Inspector-General of Civil Hospitals, Bengal, who conducted them to the dais and made an introductory speech, in which he sketched the scope and aspirations of the Calcutta School. He concluded with a strong appeal for financial help. After the laying of the foundation stone Surgeon-General Sir C. Pardey Lukis, Director-General of the Indian Medical Service, conveyed the good wishes of the Government of India for the success of the school, and expressed his own keen personal interest in the subject. Lieutenant-Colonel Leonard Rogers, I.M.S., stated that donations amounting to Rs.1,17,952 had already been received. Lord Carmichael, in the course of a sympathetic speech, referred to the interest taken by the Viceroy in the scheme, and read out a message of encouragement which Lord Hardinge had telegraphed.

March 1st.

Obituary.

BENJAMIN NEALE DALTON, M.D. LOND., L.R.C.P. LOND., M.R.C.S. ENG.

ON March 23rd Dr. Benjamin Neale Dalton, a well-known practitioner in South London, died at the age of 70, after an illness of more than five years' duration. Dr. Dalton was the son of a stockbroker and was born at Stockwell in February, 1844. He was educated at the City of London School and entered as a student at Guy's Hospital in October, 1863. There he had a distinguished career. He took the first students' prize in three successive years, and in the third year obtained the treasurer's gold medal for surgery and the treasurer's gold medal for medicine, and further was awarded a prize of £10 for a paper on Malformations read before the Physical Society. After qualifying and acting as house surgeon he read for the degree of the London University, passing promptly the preliminary scientific examination and in 1870 the first M.B. examination. He was then appointed demonstrator of anatomy, and held the appointment for two years. In November, 1872, he took the final M.B. Lond., with the scholarship and gold medal in medicine and honours in obstetric medicine and in forensic medicine. In the next year he became M.D. While teaching anatomy he started a practice in South Norwood which he continued to hold until his final illness. He was industrious and hardworking, keenly interested in the scientific side of his profession, and he acquired a large connexion and was frequently consulted by his medical neighbours. He was a constant attendant at the local medical society, before which he read several papers. He kept himself acquainted with all modern advances. He was a great reader of history and philosophy, and was fond in his spare time of gardening, carpentry, and photography. On his holidays he much enjoyed foreign travel. He was married in 1878 and leaves a widow, three sons, and two daughters.

BIRMINGHAM AND MIDLAND SKIN HOSPITAL.—The annual report states that 282 in-patients were treated during last year, and 6200 out-patients, as against 276 and 6663 the previous year. The response to the appeal for donations to the radium fund had been very disappointing, only £46 having been received.

Correspondence.

"Audi alteram partem."

THE FACULTY OF MEDICINE OF THE UNIVERSITY OF LONDON AND EXTERNAL STUDENTS.

To the Editor of THE LANCET.

SIR,—At the meeting of the Faculty of Medicine of the University of London on Thursday, March 26th, an important vote was taken on the question of exclusion of external students from the Faculty. A division by show of hands gave 21 persons voting for exclusion and 19 against. The meeting had been called by the Board of the Faculty, with due notice that a number of propositions materially affecting the whole future of the Faculty and the University would be submitted for final decision by the Faculty, and it was held at the rooms of the Royal Society of Medicine—that is, in a place offering a maximal degree of convenience for attendance. As the reasons which have been often advanced for inadequate attendances of the Faculty—namely, inaccessibility of the place of meeting and insufficient importance of the agenda—cannot here be urged, the decision must be taken to represent the real feeling of the Faculty of Medicine as a whole, and I for one so accept it.

The Royal Commissioners based their recommendation to exclude the external student from the Medical Faculty on the ground that the Faculty had "passed a unanimous resolution" in 1909 in this sense; and, further, on two arguments which they adduce, and which I shall consider immediately. The first statement can no longer be maintained; many of us think it was a travesty of fact when it was made, and it must certainly now be relegated definitely to the limbo of fiction. I submit that the division shows that opinion is nearly equally divided on the Faculty, and that there is no mandate for introducing a change, so far-reaching and so radical, for which the arguments which have been offered are so singularly unconvincing. The Commissioners, it is true, had no personal or practical experience of the problems which they were called upon to investigate. But they were carefully coached by the party which desires the extinction of external degrees in the University, and the arguments which are thought worthy to stand in the Report probably represent the flower of wisdom of these advisers. The Commissioners, in fact, make no secret of their source of inspiration. The rubric to the section (§393) summing up the opinion of the Commissioners on external degrees runs thus: "Abolition of external degrees desirable *in the interests of schools and teachers*." (The italics are mine.)

The insertion of the limiting word "certain" immediately before the phrase "schools and teachers" would make the synopsis still more accurately reflect the whole spirit and meaning of the Report, and would indeed go a long way to explain its genesis. Here are the sole arguments, which all this collective deliberation can produce, for excluding external students from the Faculty of Medicine.

> We admit the argument of several witnesses that it is an injustice to doctors who have studied in London and obtained the London degree that the same qualification should be

> open to students who have never had any connexion with the University beyond sitting in its examination halls. Every school of medicine in the kingdom is now connected with a university, and no hardship would be imposed by requiring that medical students should graduate in the university in which they have studied (Final Report, p. 160).

The Commissioners bewail the "grave injustice," as they call it elsewhere in the paragraph quoted, that the London-taught graduate should run some risk of being confused with his brother graduate who has studied in a provincial University and been awarded his degree in London, as the result of passing the same examination which the London-taught graduate has passed. The persons directly interested in this argument are the graduates of the University, who must smile at this unwonted concern for them expressed by the Commissioners when they remember that these same gentlemen recommend the reduction of the graduates' representation on the governing body of the University—i.e., the Senate—from its present ratio of nearly one-third to less than one-seventh. This is surely a much "graver injustice" to graduates. The Commissioners' sympathy is, in fact, very like the not less noisily expressed sympathy of the Walrus and the Carpenter for the oysters which they were about to devour.

As a matter of fact, the graduates have shown, as I have stated in a previous letter to you, through their proper channel—namely, Convocation, which consists entirely of graduates—an overwhelming majority in favour of a decision directly the reverse of the halting opinion expressed in the late division of the Faculty, only one-third of whose members are themselves graduates of the University.

The second argument is at once refuted by reference to the official statistics which I quoted in my last letter,[1] and which demonstrate that the number of provincial students coming to London has not been diminished since the facilities to which allusion is made for graduating elsewhere have come into existence. The Commission in effect say that the provincial student "ought" to be satisfied to stay at home. He is not so satisfied. The Government, which fathered this Commission, is at this moment engaged in trying to persuade the inhabitants of Ulster that they similarly "ought" to prefer to be governed by their fellow countrymen. They do not so prefer. The Government are finding out, as I believe the Commission will also find out, that it is not so easy a matter as they imagine to coerce the legitimate preferences of free adult men.

The Faculty has long made bitter and just complaint that at the present time too few students enter for the medical degrees of the University of London. It is an unfortunate fact that many of the best men in the metropolitan schools after completing their studies in London take degrees in the provincial Universities of Oxford and *Cambridge*. I am frankly at a loss to understand why the Faculty which encourages this system should wish to stop the compensating flow from the other provincial universities to London, by a resolution which must automatically exclude more than 12 per cent. of the students at present taking medical degrees. I can only explain this inconsistency, as it seems to me, by supposing that the majority of the Faculty still cherishes the illusion which, it will be noted, the Commissioners themselves do not harbour, that the proposed new regulation will force the provincial students to take their courses as well as their degrees in London.

The resolution passed by the Faculty would, if adopted by the University, differentiate medicine from all other faculties as they exist at present; it would dock the University of 12 per cent. of its annual pass-list in medicine, and it would withdraw privileges from a large and ambitious class of students to whom the University has offered these privileges, unchallenged, for 50 years. To justify such sweeping change its supporters must find better reasons than they have been able up to the present to produce; they must convince a much larger proportion of the Faculty of the necessity for such change; above all, "they must," to use Professor Starling's words in another connexion, "show that their 'action' is not directed by a regard for the private interests of themselves or their schools," as seems indeed to be suggested by the Commissioners themselves in the quotation I have italicised above.

I am, Sir, yours faithfully,
E. GRAHAM LITTLE.

Wimpole-street, W., March 30th, 1914.

---

[1] THE LANCET, March 14th, 1914, p. 719.

THE DUCTLESS GLANDS.

To the Editor of THE LANCET.

SIR,—I have read with interest in THE LANCET of March 28th Major R. McCarrison's letter in which he supports Professor Swale Vincent's statement to which I have taken exception. I am glad, however, to notice that Major McCarrison, who has done excellent work on diseases of the thyroid, in the last paragraph of his letter supports my general findings concerning the relationship between the ovaries and thyroid. My conclusions were based both on clinical and experimental observation, but he contends that only the clinical evidence is worthy of consideration.

With regard to Major McCarrison's criticisms of my results as to the effect of oöphorectomy upon the thyroid, I hope he will believe me when I say that I am fully aware of all the experimental difficulties he so pertinently raises; indeed, I have mentioned most of them myself in the Arris and Gale lectures and elsewhere. It is, therefore, hardly justifiable for him to cut out from my lectures two short sentences which were discussed and qualified, and obscure them with a network of side issues. This will be obvious to anyone who has read my original communications.

The points I brought out after presenting certain facts were, that the thyroid varies considerably, not only in different mammals, but in the same species in different circumstances, notably in regard to pregnancy, which is a seasonal function. And I showed, with due caution, I believe, that the thyroids of rodents, owing to the different habits and food of these animals, differ from those of the carnivora, not only normally, but also in the results obtained after experimental removal. Further, I found that in rodents, which have an inactive (i.e., non-essential) type of thyroid—in spite of the cellular appearance and scarcity of colloid—oöphorectomy increased the amount of colloid quite unmistakably in non-pregnant adult animals. My experiments can hardly be described as "few," for I have removed the ovaries from rabbits a very large number of times, and I have many sections of the thyroids from these cases. The experiment is, however, easily repeated by anyone who doubts my findings, or attributes special peculiarities to my animals, and is capable of distinguishing between the normal and abnormal in similar circumstances, and after making due allowance for the normal variations. It should be incumbent on all who adversely criticise the experimental and clinical findings of others to adduce evidence to the contrary. It is a constant source of wonder to me why so many men, whose own scientific work may be accurate and valuable, should always be ready to criticise the work of others on purely theoretical or imaginary grounds, when experimental repetition is easy and conclusive. The investigator who is incapable of making a mistake has yet to be born, and I am merely defending my own findings and statements because they have not yet been shown to be wrong; when they are proved by scientific evidence to be erroneous in any particular I shall be the first to acknowledge the fact, even if I make the discovery myself.

I am, Sir, yours faithfully,

Liverpool, April 1st, 1914. W. BLAIR BELL.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 28th Major Robert McCarrison has an interesting letter on the structural variations that he has observed in the thyroid glands of rats, in association "with locality, with altitude, with season, with food, as well as with the hygienic conditions incidental to confinement in cages," his conclusions being based on the study of the histological appearances of the thyroid glands of about 450 rats.

As the result of an even more extensive investigation carried out many years ago I was led to conclude that the food factor was of special importance. I then drew attention to the fact that the histological appearances of the thyroid gland in any group of rats obtained at the same time from one source conformed to one type, but that various types were obtainable, these doubtless corresponding to different degrees of activity of the gland of a nature at present ill understood. The different histological appearances observed were illustrated in the *Journal of Experimental Physiology* many years ago. Another point which was brought out by my observations was the influence of diet in modifying the structure of the gland, the changes observed being of a very striking kind, though not constant in character. Major McCarrison further refers to the striking variations which he has observed in the thyroid glands of rabbits and guinea-pigs. I can confirm this statement, and the same can be said of the thyroid gland in pigs. At one time I examined the thyroid gland of a large number of pigs and was impressed by the differences observed in the histological appearances. This is, perhaps, not very surprising when one considers the differences observed in the naked-eye appearances of the carcasses. The colour of the muscle and the colour and consistence of the fat vary enormously, this being due, in the view of the butcher, to the feeding of the animal, the commercial value of pork from animals fed on "hard" food being considerably higher than of animals fed on so-called "soft" foods (chiefly brewery refuse).

A fruitful field for investigation is open to those who have facilities to investigate some of the interesting problems suggested by the facts brought out in Major McCarrison's letter.

I am, Sir, yours faithfully,

CHALMERS WATSON, M.D. Edin.

Edinburgh, April 1st, 1914.

MINERS' PHTHISIS ON THE RAND.

To the Editor of THE LANCET.

SIR,—A letter of mine upon the above subject kindly published by you in THE LANCET of Dec. 2nd, 1911, caused at the time an outburst of indignant protest both from the mine-owners and their official organs. My figures were said to be exaggerated and my assertions false. But my figures were very sadly underestimated, and my assertions upon this very grave subject had never been proved to be otherwise than correct. The statements and figures of the mining houses and the Government, on the other hand, can seldom be relied upon, for the simple reason that this disease is cursed with the damnable political insincerity of both the above parties.

Commission after commission has been formed and packed with incompetent persons, with the result that to-day silicosis is more prevalent than it has ever been. In 1911 roughly 12,000 white men were employed below on these fields; to-day the total has fallen to about 10,000. In 1911 three men per day applied for relief; to-day it is nearer ten, and accumulative claims must have been disposed of long ago. Therefore, so far all the supreme efforts of the mining houses and their servants must be written down a complete failure, and the sooner this is recognised and faced the better.

In order to refresh your readers' memories I may say that it has long been held by medical men, both here and in Australia, that it is only the very finest dust caused by drilling, blasting, and moving rock which produces silicosis. The condition upon the Rand must not be taken to be unique for the production of silicosis. It must be clearly remembered that silicosis, and rapid at that, occurred during the excavation of a large open drain through sandstone in Sydney not many years ago. This, together with all the other occupations well known to produce silicosis, does away with the theory that it is entirely caused by the dust from blasting. To those unacquainted with the process of rock drilling I would point out that though water may be freely used in the form of a spray from the moment the drill hits the rock to the end of a 4 foot or longer hole, there is a time when it does not effectually destroy the finest dust. This period is when the drill is hammering and chipping away at the rough uneven surface of the rock in order to gain a start for the hole. This process is termed "collaring the hole." More frequently than not no water is used during this process, which provides abundance of the deadly dust. Another difficulty to be faced is the constant breaking down of water-supplies; these for the most part are avoidable and due to too great pressure, corroding of unprotected pipes, &c. Almost all these difficulties could be overcome by a small exercise of common sense on the part of the mining engineer; but, no, the same stupid system and mistakes are made year after year irrespective of the consequences.

The mining authorities would hold that by improved ventilating methods the dust caused by blasting has been largely overcome. If this is so, why is miners' phthisis more virulent than ever? I do not hesitate to say now what I have said before, that the continuous forced passage of dust-laden air through places where men are working can be of little advantage, if any. The dust must be rendered harmless as much as possible at its point of origin. If the fine dust is entirely produced by blasting, then, according to the theory of the mining engineer, it should be all carried out of the mine before the men re-enter to work. The fact remains that sufficient of the really fine fatal dust (irrespective of blasting) is produced by the rock drills to account for the whole of the silicosis on the Rand; and yet let me point out how the mining houses deal with this vastly important matter.

Rock drills are placed in numerous positions on the mines and are mostly worked by kaffirs under the direction of white miners. Your readers will note I say under the direction. Now, to show the attitude of the mining houses as to this terrible disease I will illustrate what was being done before the late industrial upheaval and what is taking place to-day. Before the strike the miners through their union endeavoured to limit the number of machines each man should supervise; upon the whole they were fairly successful. To-day there is no limit, and no limit means no control as regards the keeping down of dust produced by rock drills. If the mining houses and the Government (which are practically one) were honestly sincere in their efforts to stop this curse, they would surely insist on the efficient control of every drill. This by no means implies that one miner is necessary for every drill when one or more are placed together, but, with few exceptions, one miner only can supervise one drill properly when working any distance up a raise. The production of the finest dust from a rock drill means, when circulating as it freely does, the death element to everyone working in the mine.

I believe I am right in the following facts; if not, I hope your readers on the spot will correct them. Miners' phthisis was well known not many years ago in ganister mines near Sheffield. The question received the serious attention of the Home Government, with the result that it has now practically ceased. To prove the keen interest in stamping out this disease shown by the mining houses and the Government I must add the following. The medical officer to the said ganister mines both during and after measures taken to prevent this disease was here on the Rand last year, and upon his information I published in the press the facts he gave me, and also suggested that his opinion should be of the greatest value. What notice was taken? Absolutely none. "No experts wanted from oversea except when required for political purposes" might well be written over the doors of the mining houses. I believe I am right in saying that the Home Government insisted upon the fine dust produced in ganister mines in England being kept down by the use of steam, when miners' phthisis ceased.

The fact which has to be grasped by those who seriously wish to see our vast industry freed from silicosis, is that water in the form of sprays, &c., has failed to diminish the disease. The fact that steam has eradicated miners' phthisis in the ganister mines points to the fact that in order to attract the very finest and most deadly dust the water must be in a much finer state of division, and this can only be produced by steam. If the simple experiment is made of forcing dust through a volume of water, the difficulty of destroying the fine dust which emerges is readily seen. Steam therefore appears to be not only the only hope, but by experience elsewhere the only sensible solution left. Mr. Moynihan, the well-known consulting engineer, pointed out how steam could be introduced after the cessation of drilling through the compressed air pipes. The question at what depth this would be impracticable, if at all, remains to be seen. Anyhow, it would only seem common sense to gradually work down from level to level. Something more must be done to prevent this awful waste of life, and that at once.

I am, Sir, yours faithfully,
J. L. AYMARD.

Johannesburg, March 16th, 1914.

THE BIOLOGY OF TUMOURS.

To the Editor of THE LANCET.

SIR,—I am much obliged to Mr. H. C. Ross for his kindly criticism of my lecture upon the Biology of Tumours published in your issue of March 21st, and for directing attention to the action of substances known as auxetics. All that he says simply confirms the views I ventured to put forward. As their name implies, auxetics do but add to a force that is already present. They supply nothing that does not exist already.

But I cannot agree with Mr. Ross that it has been proved that certain cells will not divide unless they absorb a definite chemical stimulus. A general negative such as this is not capable of proof, nor if it were proved, is division the only form of growth. Growth does not of necessity imply even increase in size. When the chemical processes that underlie growth come to an end life comes to an end with them.—I am, Sir, yours faithfully,

C. MANSELL MOULLIN.

Wimpole-street, April 6th, 1914.

"THE MENACE OF CANCER" AND AMERICAN VITAL STATISTICS.

To the Editor of THE LANCET.

SIR,—The Director of the Imperial Cancer Research Fund, Dr. E. F. Bashford,[1] goes far out of his way in his attack on the trustworthiness of American vital statistics and incidentally on the accuracy of my conclusions that cancer is on the increase in the United States, as discussed at some length in my address on "The Menace of Cancer" before the American Gynecological Society, in 1913. The argument of Dr. Bashford, if it can be dignified by that name, is not new, for he gave expression to practically the same views in his first address on the cancer problem, delivered in the United States in 1912. Regardless of the fact that I personally called his attention to the gross inaccuracies of his statements, he repeats his misleading assertions, and fain would make the world believe that the Americans still live in the Dark Ages and that the pathologist knows more about statistics than one professionally connected with statistical research. It would take up more space than is likely to be available for a full reply to answer even briefly the numerous misstatements on the part of Dr. Bashford, who practically limits his remarks to American vital statistics, which, in his opinion, are thoroughly untrustworthy and useless for the purpose of establishing the truth about the cancer situation at the present time and in the recent past. It is to be hoped, however, that in behalf of the cause of statistical science, medical progress, and simple justice to the undersigned sufficient space will be granted to establish concisely the facts in the case. My address on "The Menace of Cancer" was first delivered, by request, before the Academy of Medicine of Northern New Jersey, and subsequently, by invitation, before the American Gynecological Society, the Clinical

---

[1] THE LANCET, Feb. 7th, 1914, p. 379.

Congress of Surgeons of North America, the Eastern Medical Society of the City of New York, the Wistar Institute of Biology and Anatomy of Philadelphia, the Academy of Medicine of Pittsburgh, &c. There has not come to my notice a single qualified contradiction of a single important statement made in the address on the part of an American medical journal in a position to pass judgment upon the facts. The address was delivered for the purpose of emphasising the seriousness of the cancer problem, of illustrating the frequency of cancer occurrence, and of arousing a public interest in the necessity of educating the public in the plain facts of cancer, as a prerequisite for a nation-wide campaign for cancer control. The address was largely instrumental in bringing into existence the American Society for the Control of Cancer, which has on its board of trustees some of the foremost physicians and surgeons of America, and of the Committee of Statistics of which I have the honour and the privilege to be the chairman. To the address itself Dr. Bashford gives practically no attention, but he requires more than three pages for his bitter, unwarranted, inaccurate, and unjust attack upon American vital statistics.

1. He questions the accuracy of the assertion that the cancer death-rate of the United States has increased from 63 to 74·3 per 100,000 of population during the period 1900–11. The term "United States" is used as a matter of convenience, for the rates refer to the "registration area," which by the year 1911 included 63·1 per cent. of the population of the country. On the part of one familiar with local conditions, it is entirely safe to assume that the conclusion which applies to the registration area applies with approximate accuracy to the remainder of the country not at present under registration. For the end in view it is, however, entirely immaterial whether the conclusion applies only to the registration area or to the country as a whole. There is no reason whatever for supposing that there has not been a corresponding increase in the cancer death-rate for the remainder of the country at present not under registration. Considering that the population under registration in 1911 amounted to 59,275,977, it will be observed that the actual numbers considered were far in excess of the corresponding population for England and Wales, or, for that matter, for the United Kingdom as a whole. The numerical basis for the conclusions was, therefore, sufficiently large and representative of the United States as a whole, but aside therefrom, the statistics of large cities were considered separately and for a much longer period of time.

2. Dr. Bashford deplores the "very backward condition" of vital statistics in the United States at the present day. There is no country in the world for which accurate vital statistics are available for so large a population, thoroughly digested in detail according to age, sex, and certified causes. The area at present not under registration represents vast sections of country sparsely populated and large regions in the south with a predominating negro population.

3. Dr. Bashford deplores that centralisation for the recording of births, marriages, and deaths has not yet been effected in the United States, and that recourse must be had to the reports for the several States. This statement is misleading. Neither the United Kingdom nor the German Empire, nor many other important civilised countries. have a centralised or federal system of recording deaths, with which the present discussion alone is concerned. By an arrangement with the Division of Vital Statistics a certified transcript of every death is obtained for what is known as the registration area, which includes either entire States or cities and towns which, upon the basis of thorough investigation, have been found to maintain a system of death registration satisfactory to the Census Office. Granting that absolute accuracy is not obtainable by this method, it is maintained without fear of contradiction that the degree of accuracy is approximately the same as for other civilised countries and that a system of Federal registration is not necessary, nor would such a system provide a material increase in the accuracy and completeness of the facts.

4. According to Dr. Bashford, "in 1880 the compulsory registration of deaths, as enforced by municipal or State authority, was first introduced at Massachusetts, New Jersey, the District of Columbia, and for some cities where State control did not obtain." As a matter of fact, the compulsory registration of births, marriages, and deaths was established in the State of Massachusetts under date of March 3rd, 1842, and annual reports, with reasonable completeness, have been published for that State since that year. Registration in the State of New Jersey was established in 1848, in the District of Columbia in 1878, in the State of Vermont in 1857, in the City of Providence, R.I., in 1855, &c.

5. The statement is made that "the Southern States are still *entirely* without any sort of reliable registration." As a matter of fact. most of the large cities of the South have had in force the compulsory registration of deaths for many years. For New Orleans the statistics extend over half a century, and practically the same is true of Mobile, Savannah, and Charleston.

6. It is true that the present registration area includes only 22 out of the 48 States of the United States, but additional thereto the registration area includes municipalities of 1000 and over in the State of North Carolina and 47 other representative cities, which combined with the registration States represent 63 per cent. of the total population of the Unites States, a population sufficient for the purpose of arriving at a trustworthy conclusion regarding American mortality from all causes, as well as from cancer.

7. Dr. Bashford, on the authority of Oertel, claims that New York City "has shown that the greatest laxity and inaccuracy obtains, owing to the neglect of the medical profession and the unwillingness of the authorities to enforce the prescribed penalties." The views of Oertel have not been accepted by qualified critics, although justified to a limited extent as regards initial diagnosis in hospital practice, which has but an indirect bearing upon the terminal certification in death registration. There is no laxity or gross inaccuracy inherent in the vital statistics of the City of New York, which are accepted by every authority on vital statistics throughout the world. The compulsory registration of deaths has been in force in the City of New York since 1865, but for half a century previous deaths were recorded in a more or less trustworthy manner and probably as accurately and conclusively as for most of the large cities of the world during the corresponding period of time.

8. According to Dr. Bashford an "attempt" is made in North Carolina and the district of Columbia to enforce registration. As a matter of fact, the local ordinances governing the registration of

deaths are enforced with reasonable completeness in the towns of North Carolina, and with entire completeness in the District of Columbia, where compulsory registration has prevailed since 1878.

9. The fact that 37 per cent. of the population of the United States are not at present within the registration area has no bearing whatever upon the trustworthiness of conclusions based on the statistics for the population subject to registration at the present time.

10. The statement that previous to 1902 "no two States and scarcely any towns used precisely the same methods of certification of deaths" is, broadly speaking, incorrect. No country in the world has adopted a uniform method of "certifying" deaths and no such law could be enforced. The accuracy and uniformity of death certification depends upon the attained state of medical science and not upon legislation. The use of a standard death certificate facilitates statistical analysis and improved classification, but it has no immediate bearing upon the accuracy and completeness of death certification itself as regards the causes of death.

11. It is claimed by Dr. Bashford that the standard death certificate was "revised by Act of Congress in April, 1913." As a matter of fact, there was no such revision, and Congress has no authority under the Constitution to make the use of a standard death certificate obligatory upon the several States or municipalities having adopted a system of compulsory registration.

12. The view of Dr. Bashford that "no comparison is possible between one year and another for the United States, or even between different States," is a self-evident absurdity. For a group of States with an area larger than the United Kingdom and a very considerable population comparable statistics have been available for half a century, and for a large number of representative cities comparable records are extant for an equal if not a longer period of time. For the registration area itself a strictly accurate comparison can be made from year to year, and the changes in the death-rate from all causes or specified causes can be determined with the required degree of scientific accuracy.

13. Dr. Bashford becomes quite serious when he remarks that "it must be added *emphatically* that even the States longest under the compulsory registration law, e.g., Connecticut and Massachusetts, have not yet succeeded in enforcing registration of *all* births." Waiving the question that the registration of births has nothing whatever to do with the question as to whether cancer is on the increase or not, it may be said that the registration of births in the State of Massachusetts is probably as nearly accurate as for most of the other civilised countries of the world. In no country are "all" births recorded, and it is only within very recent years that stillbirths were required to be reported in England and Wales.

14. The total population of the United States according to the Census of 1910 is given by Dr. Bashford as 90,753,237. The correct figures for the United States, exclusive of outlying possessions were 91,972,266.

15. Dr. Bashford claims that "the infantile mortality in the registration area of the United States cannot be estimated with any approach to accuracy." As a matter of fact, the annual reports of the Division of Vital Statistics of the Census give the number of deaths at ages under 1 by days, weeks, and months, and the proportion of such deaths to the total mortality on the one hand, or to the population at ages under 1 on the other, is the usual method by which the infantile mortality is calculated. It no doubt is of value to determine the proportion of deaths under 1 to the number of births, but it is entirely wrong to say that the infantile mortality in the registration area of the United States cannot be estimated with any approach to accuracy. The question is entirely irrelevant in the discussion of the question as to whether cancer is on the increase or not.

16. Dr. Bashford observes in all seriousness that "it is also common knowledge that the age constitution of a population is determined by the birth-rate, if immigration and migration be left out of account." The age constitution of every civilised country is affected far more by immigration and migration than by the birth-rate, and the question itself is therefore irrelevant, aside from the fact that it has nothing whatever to do with the problem of cancer.

17. Dr. Bashford maintains, in flat contradiction to the facts, that "the age constitution of the United States is simply unknown." In my address on "The Menace of Cancer" hundreds of cancer death-rates are given on the basis of population by divisional periods of life, including an official table for the registration States, calculated by the Division of Vital Statistics, giving the accurate rates for divisional periods of life and the crude and corrected rates for ages 25 and over. The statement that the age constitution of the population of the United States is unknown is preposterous. The United States took a census 11 years before one was taken in the United Kingdom. Even the Census of 1790 made a distinction of the population above and below the age of 16. The Census of 1800 gave the age constitution by five divisional periods of life. Beginning with the Census of 1830, the age constitution was given by decennial periods, which for all practical purposes meets all reasonable requirements. For more recent census periods the full analysis of the mortality by single years of life has been published, in conformity to approved census methods throughout the world. The statement, therefore, repeatedly made, that the age constitution of the United States is unknown is simply additional evidence of the gross ignorance of Dr. Bashford of the facts and conclusions which he essays to discuss with pretended scientific accuracy and fairness.

18. Dr. Bashford comments upon "the confused state of affairs in the United States as regards the vital statistics of that country." There is no confusion in the minds of Americans who make use of American vital statistics and who are familiar with the facts. The confusion exists solely in Dr. Bashford's mind, who apparently considers himself immune against criticism in matters which admit of no controversy at all.

19. Regardless of the fact that in my address on "The Menace of Cancer" there are hundreds of cancer death-rates according to age and sex and a number of diagrams concisely visualising the facts, the Director of the Imperial Cancer Research Fund again maintains that no account is "being taken of age and sex." Not only does the address referred to give the rates by age and sex, but also by race and age, and by organs and parts of the body according to sex and divisional periods of life. The statement is, therefore, without qualification, in flat contradiction of the truth.

20. The conclusion that "the absence of accurate enumeration of the number of births makes it impossible to estimate the proportion of males and females" is a self-evident absurdity. The proportion of males and females has been known for the population of the United States since the taking of the first Census in 1790, or 11 years before a census was taken in England.

21. In continuation of his remarks Dr. Bashford repeats: "Since the age and sex constitution of the population is unknown, this claim (of an increase in the mortality from cancer) cannot be upheld." In reply, I quote the following from my address on "The Menace of Cancer" as a further illustration of the indifference of Dr. Bashford to the facts:—"For males the increase in cancer during the 10-year period and at ages of 45 to 54 was 21 per cent.; at ages of 55 to 64 it was 39 per cent.; at ages of 65 to 74 it was 40 per cent.; and at ages of 75 and over also 40 per cent. For females the increase in the cancer death-rate at ages of 45 to 54 was 11 per cent; at ages of 55 to 64 it was 27 per cent; at ages of 65 to 74 it was 32 per cent; and at ages of 75 and over 44 per cent."

22. Dr. Bashford maintains that my tables of cancer mortality per 100,000 of population by sex "have an appearance of accuracy which cannot be maintained." Dr. Bashford omits to say that in practically all of the tables included in the address the rates are given by age and sex, and there is no *pretended* accuracy about them whatever. The table referred to was derived from the Vital Statistics of the Census for the registration States of 1900, and the required comparison is made for the two years 1901 and 1911, with a due regard to sex and 11 divisional periods of life. No more trustworthy or conclusive table of cancer mortality is published for any corresponding number of population in the world.

23. Dr. Bashford, apparently, is of the opinion that a low cancer death-rate is an evidence of improved registration, or as indicating only the stage to which vital statistics have developed. On this assumption the highest cancer death-rate of any one county of England and Wales would be the index of impaired registration in every county with more or less decidedly lower rates of cancer frequency. Apparently the Director of the Imperial Cancer Research Fund wants the world to believe that there are no local variations in the cancer death-rate, or that, in other words, neither local conditions nor race are determining factors, but that it is simply a question of imperfect registration. The conclusion of Dr. Bashford that "an accurate method simply cannot be adopted for the United States as a whole, or even for one or two States, if, indeed, for any single city," is a self-evident absurdity.

24. Reference is made to the method of cancer classification in the reports of the State of Connecticut for 1910. Dr. Bashford must have read this report as superficially as he did my address on "The Menace of Cancer," for on p. 213 of the report the mortality from cancer is given in detail by organs and parts of the body affected and by divisional periods of life. The inclusion of cancer deaths in the division of general diseases and as a subdivision thereof is in exact conformity to international usage on the basis of the revised international classification. Since the Connecticut reports were not used in my address on "The Menace of Cancer," the reference thereto is irrelevant.

25. Similar references are made to the statistics of Rhode Island, New York City, and New Jersey, all of which illustrate Dr. Bashford's ignorance of American vital statistics far more conclusively than they demonstrate any inherent or practically important defects in American vital statistics.

26. There are numerous other misstatements, false inferences, or references reflecting upon Americal vital statistics, which it would be superfluous to discuss in detail.

Practically the entire paper by Dr. Bashford is a meaningless jumble of inaccurate, misleading, and purposeless observations regarding a subject with which he has at best a very superficial acquaintance. He refers to the abandonment of the former method of enumerating deaths upon the decennial census, which has no bearing on the subject under consideration. He refers to the cancer censuses of Germany and Hungary, which are only very incidentally dealt with in my address on "The Menace of Cancer." The practical value of cancer censuses has been by no means disproved by the superficial, inaccurate, and misleading observations of Dr. Bashford on that particular subject. No reference was made to immigration or migration, since these are but incidental factors fully allowed for in the use of accurate population statistics according to age and sex. The fundamental question as to whether cancer is on the increase or decrease in the United States is not discussed by Dr. Bashford at all. No evidence has been produced to prove that it is wrong or misleading to speak of an increase in the mortality from cancer, nor are my observations regarding the cautious use of the data made mention of in Dr. Bashford's observations. The assertion that the position taken by King and Newsholme in 1893, that the increase in cancer is only apparent and not real, "has been amply justified" is again a deliberate misuse of Dr. Bashford's opportunity to force his own opinions upon the public.

The conclusion of Dr. Bashford that "the statements of the alleged increase of cancer in America have only the value of vague rumours" is entirely unjustified by the incontrovertible fact that at least 75,000 deaths from cancer occur annually in the United States and that the time has come for a nation-wide interest in the problem of prevention and control. The work undertaken in America will be carried forward with a genuine devotion to the truth and with a due regard for all the facts and conditions affecting the cancer problem as a public question which requires to be taken into account. In any event, American students of the cancer problem will give slight consideration to the unfair, inaccurate, and misleading observations and conclusions of one who has demonstrated, as shown by the foregoing analysis, his utter unfitness to be considered a guide in cancer research from a statistical point of view.

I am, Sir, yours faithfully,
FREDERICK L. HOFFMAN.

Newark, New Jersey, March 10th, 1914.

*** Dr. Bashford's article was an uncompromising one, and Mr. Hoffman's tone, though regrettable in scientific controversy, has been inspired by that fact, as has our extension to Mr. Hoffman of a quite unusual space in which to reply. The main question at issue is the value of the machinery for collecting and collating American vital statistics, and the trustworthiness of the results obtained. To say that a district is in a "registration area" is not a conclusive reply to criticism. It is a prelude to such reply: systems of registration may have nominally existed from the earlier part of the nineteenth century and yet be practically ineffective until far more recent times. Mr. Hoffman's remarks on British administration in many directions have exactly the same justification. In places where Mr. Hoffman contradicts Dr. Bashford he is himself contradicted by the Department of Commerce: Bureau of the Census of the United States.—ED. L.

EPITHELIOMA OF THE TONGUE IN WOMEN.

To the Editor of THE LANCET.

SIR,—The case of epithelioma of the tongue in a woman referred to in an annotation in THE LANCET of March 28th is important as calling attention to the comparative infrequency of this affection in the female sex. This infrequency is not so much recognised as it should be. But besides carcinoma of the tongue it applies to cancer of all parts of the mouth, pharynx, and larynx. This is shown by the Registrar-General's reports. In the past 11 years there have been in Woolwich 182 cases of cancer of the head; face, mouth, jaw, tongue, œsophagus, pharynx, larynx, and neck among men and only 47 among women.

The connexion of cancer of the tongue with smoking is well known, though it is usually attributed specially to clay pipes. Recent inquiries made in this borough point to the fact that any kind of smoking is a cause of cancer of the mouth and throat, especially when connected with alcoholism. Of 33 persons dying from cancer of the mouth and throat 45 per cent. took alcohol excessively, and 76 per cent. smoked excessively. Of 109 persons dying at advanced ages from other diseases 17 per cent. only were excessive smokers and 18 per cent. excessive drinkers. Of 25 excessive smokers who died of cancer of the mouth and tongue 15 smoked chiefly clay pipes, 8 briar or other form of pipe, 1 cigars, and 2 cigarettes. Among the non-cancer cases there were 40 smokers (excessive and moderate); 23 of these smoked clay pipes, 16 briar, and only 1 cigarettes. Out of 33 cases of cancer of the mouth and tongue there were only two who did not smoke. One of these had bad teeth, and in the other one, as in the case reported by you, there was no obvious source of the cancer.

I am, Sir, yours faithfully,
SIDNEY DAVIES.
Woolwich, March 28th, 1914.

To the Editor of THE LANCET.

SIR,—In an annotation in THE LANCET of March 28th the occurrence in the female sex of epithelioma of the tongue is referred to as being extremely rare. This statement is hardly in accordance with the facts. Keyser[1] quotes 14 sets of statistics of epithelioma of the tongue bearing on the relative frequency of the disease in women; the highest estimate, that of Hayn. is 43 per cent., while the average of all the statistics gives a percentage of over 18. A feature of some of the recorded cases is the youth of the patient.

Keyser refers to five cases in which the patients were under 25 years of age, and in a case of my own[2] the patient, whose disease had existed for 21 months, died at the age of 26 years.

I am, Sir, yours faithfully,
C. HAMILTON WHITEFORD.
Plymouth, March 28th, 1914.

AERIAL INFECTION.

To the Editor of THE LANCET.

SIR,—The annotation in THE LANCET of March 28th on the Passing of the Doctrine of Aerial Infection raises some important questions. Whatever the danger from air-borne infection may be, it is at any rate certain that no infectious disease has been brought by precautions against it, such as isolation hospitals, under such control as has been obtained in a series of diseases, ranging from enteric to yellow fever, by other means. The advantages secured for the individual or the family are not in question, but only those for the nation.

Is it then not probable that the scheme for preventing the spread of tuberculosis devised by the Astor Commission and adopted by the Insurance Act, to carry out which sanatoriums are being built all over the country, is founded on a mistaken idea, and may even check the diminution of mortality from pulmonary phthisis which began about 1850, before sanatoriums were dreamt of, proving that there are indirect methods by which this disease may be diminished?

Few diseases are less capable of effective isolation than phthisis. Isolate as one may, the air will still contain bacilli enough to infect the really susceptible. The larger the number of cases in which an arrest of this disease is obtained the more numerous will be the descendants from the more easily infected stocks. It is impossible to abrogate the law that a race is weakened by encouraging the survival of those unfit for the conditions under which they have to live, but it is possible to improve those conditions so that more may be able to survive with advantage to themselves and others.—I am, Sir, yours faithfully,

MICHAEL THOS. SADLER, M.D. Lond.
Brook Green, S.W., March 28th, 1914.

INFANT MORTALITY AND THE WELFARE OF INFANCY.

To the Editor of THE LANCET.

SIR,—Will you allow me to say a word on the subject of your annotation in THE LANCET of March 28th on the representation made to the General Medical Council by the National Association for the Prevention of Infant Mortality regarding the necessity for including in the curriculum a course of training in infant hygiene?

Everyone will agree with you in deprecating the addition of even a feather's weight to the burden imposed upon the student, and will assent to your proposition that in a readjustment of that burden lies the true direction of reform. And in the enlightened support you give to the proposal in question you indicate that the "little more" it involves should, in fact, provide the necessary readjustment. I wish to offer testimony in favour of this view, for I believe that such training will at once vivify, reinforce, coördinate, and illuminate the whole course of academic study. I can best illustrate the point at issue by a reference to a remarkable paper[1] by Dr. James Mackenzie, in which he presses home, in a masterly way, a criticism of the prevalent tendency of the methods of clinical teaching, and points the way to a better and fuller realisation of the resources in the talents of our teachers and the material at their disposal, on which the advance of changes in the text of it in his Bill because he had been in consultation with the Privy Council and the Scottish Office and desired to meet their views. The main objects of the Bill were to provide that after 1916 no woman who was not certified as competent should take or use the title of midwife, and after 1921 further limitations were to be put on women who attended at childbirth and those who were not certified. All this was subject to reasonable provisions to protect the interest of those who were now practising. The Bill also constituted a Central Midwives Board for Scotland to carry out the Act under the Privy Council, and it set out at some length the powers and duties of the Board. There were provisions for the discipline of midwives, for expenses, and for dealing with offences. The local authorities for carrying out the provisions of the Act and for the supervision of the certified midwives would be the county councils and the town councils. When there were district committees where the counties were divided into districts these would have duties under the Bill. It was provided that the term "local authority" should have the same meaning as in the Public Health Act, 1897. The reason for that was that they were anxious to avoid the prejudice created in the minds of the medical profession and amongst midwives if they were to any extent to be put under the Poor-law. He had also been in communication with the Committee of the British Medical Association for Scotland, and he had accepted one or two suggestions which that body had put forward. The Local Government Board for Scotland were in favour of legislation on the lines of this Bill. The Medical Service Committee for the Highlands and Islands had passed a resolution strongly advocating a Bill of this kind. The medical officers of health of all the large towns in Scotland which he knew were in favour of it. The Scottish maternity hospitals for the four great centres of medical education were also in favour of it. The Nursing Association, which held an important conference at Glasgow last month, passed a resolution urging on the Secretary for Scotland the great need for an Act for the protection of women in childbed and the supervision of midwives. One of the matters which had ripened opinion in Scotland in favour of the Bill had been certain provisions of the National Insurance Act. He believed that the Insurance Commissioners also thought that the Bill was necessary for the poorest women in the community.

[2] Bristol Medico-Chirurgical Journal, March, 19[illegible], p. 45.

[1] On the Teaching of Clinical Medicine, Brit. Med. Jour., Jan. 3rd, 1914.

Earl BEAUCHAMP, on behalf of the Government, said that whilst they could not pledge themselves as to the details of the Bill, thought that it would prove of inestimable value.

The Bill was then presented and read a first time.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 25TH.

Coroners' Inquests.

Mr. HIGHAM asked the President of the Local Government Board what were the new Regulations which had been issued to coroners which made it necessary for the holding of inquests in every case where the deceased might not have been attended by a regular practitioner.—Mr. HERBERT SAMUEL replied: No Regulations have been issued to coroners. The Regulations recently issued to Registrars of Births and Deaths do not have the effect suggested or in any way diminish the discretion of the coroner as to whether an inquest is or is not necessary.

WEDNESDAY, APRIL 1ST.

Nursing Home in Sierra Leone.

Mr. MACCALLUM SCOTT asked the Secretary of State for the Colonies whether, before sanctioning the proposed rule prohibiting patients in the Sierra Leone nursing home from being treated by their private practitioners, he would consider the peril to recovery which might arise through denying to patients suffering from a disease the continued medical skill of their regular medical practitioners who alone would possess the history of the case.—Mr. L. HARCOURT replied: My honourable friend may rest assured that full consideration will be given to this and all other aspects of the question.

Mr. MACCALLUM SCOTT asked the right honourable gentleman whether he was aware that a white man was recently removed to the Sierra Leone nursing home suffering from blackwater fever; that he had previously been treated by a native doctor with high qualifications in whose skill in the treatment of tropical diseases confidence was reposed not only by the native population but by many of the white population; that the patient applied to the authorities of the nursing home to allow him to be treated by his regular medical attendant, but that in view of the proposed new rule this was at first forbidden, but afterwards permitted; and whether he had received any representations of public opinion from Sierra Leone on the subject of the proposed treatment.—Mr. L. HARCOURT answered: The circumstances of the case to which my honourable friend refers are not within my knowledge. I am not sure that I understand the last part of the question, but I have received no representations of public opinion from Sierra Leone on the subject of the proposed new rule to which my honourable friend refers.

Small-pox in Germany.

Mr. POINTER asked the President of the Local Government Board to state the number of small-pox cases and deaths in the German empire and in Prussia respectively during each of the years 1892 to 1912.—Mr. HERBERT SAMUEL wrote in reply: The number of cases of and deaths from small-pox in Germany and in Prussia respectively since 1891 are given in the appended table so far as figures have been published up to the present date. The figures as to cases and deaths are obtained from the final official reports of the countries concerned. The figures as to deaths differ slightly from those published in the English Registrar-General's annual reports, which have been derived from unrevised earlier statistics.

Small-pox.

Year.	German Empire.		Prussia.	
	Cases.	Deaths.	Cases.	Deaths.
1892	?	108	?	91
1893	?	157	?	137
1894	?	88	?	77
1895	?	27	?	24
1896	92	10	70	8
1897	45	5	29	5
1898	129	15	112	12
1899	346	28	314	25
1900	392	49	349	45

Funds for Sanatorium Benefit in Wales.

Mr. GODFREY LOCKER-LAMPSON asked the honourable Member for St. George's-in-the-East, as representing the National Insurance Commissioners, whether his attention had been called to the statement of the medical officer of the Welsh Insurance Commission that the number of insured cases receiving domiciliary treatment was small and did not warrant the sum spent for them—namely, 6*d*. per insured person, paid to the panel doctors; whether several Insurance Committees had found themselves short of funds for sanatorium benefit in consequence of the above 6*d*. being diverted from them; and whether he proposed to make a temporary grant to needy Insurance Committees so that consumptive insured persons might receive the sanatorium benefit which they needed and to which they were entitled.—Mr. WEDGWOOD BENN answered: My right honourable friend understands that the report contained in the honourable Member's question does not accurately represent the observations of the officer in question. These were addressed solely to the circumstances of a particular area in which domiciliary treatment had in many cases been given without formal recommendation for sanatorium benefit. With regard to the latter part of the question I would remind the honourable Member that expenditure upon domiciliary treatment is part of the committee's expenditure upon sanatorium benefit as a whole, and that extensive grants are already provided towards the cost of comprehensive schemes comprising arrangements for the treatment of insured persons.

Mr. WORTHINGTON EVANS: Has a surcharge been made in cases where domiciliary treatment has been given without advice?—Mr. WEDGWOOD BENN: No, it will depend on the circumstances of the case.

Mr. WORTHINGTON EVANS: In the circumstances of the case to which the honourable Member has referred will it be so?—Mr. WEDGWOOD BENN: I cannot say.

THURSDAY, APRIL 2ND.

The International Opium Convention.

Answering Mr. THEODORE TAYLOR, Sir EDWARD GREY, the Foreign Secretary, stated that since the end of January he had not been informed of the adherence of any Power then outstanding to the International Opium Convention. The Powers that had not yet adhered to the International Opium Convention were being constantly pressed to do so, and it was confidently hoped that the difficulties which stood in the way of their adhering might shortly be overcome. It was very desirable that the ratification of other Powers should be secured as well as that of His Majesty's Government.

Treatment of Tuberculosis in Ireland.

Mr. LARDNER asked the Chief Secretary to the Lord Lieutenant of Ireland whether any of the county authorities in Ireland, in preparing schemes for the treatment of tuberculosis, proposed to treat non-pulmonary tuberculosis; and, if so, would he state the names of such authorities and say whether such treatment was proposed to be at the patients' homes, by dispensaries, or in sanatoria.—Mr. BIRRELL *replied*: Provision for non-pulmonary tuberculosis is generally included in county schemes, and the county infirmaries of Armagh, Waterford, Louth, Londonderry, Dublin, Mayo, Queen's County, King's County, Tyrone, Carlow, Leitrim, Galway, Cork (2), Fermanagh, Sligo, Meath, and Antrim have been approved by the Local Government Board for the purpose. Treatment will be provided institutionally or otherwise according to the circumstances of the case.

Mr. LARDNER asked the right honourable gentleman what counties in Ireland were providing their own sanatoria for the treatment of tuberculosis under the National Insurance Act, Part I., and how many were contracting for accommodation for their patients in proprietary institutions; whether any of the county sanatoria were in full working order; and, if so, would he state the counties and the total number of beds provided under each system.—Mr. BIRRELL said in reply: The county boroughs of Dublin, Belfast, and Cork, and the counties Clare, Limerick, Cork, Galway, Tipperary (North Riding), Dublin, Sligo, Tyrone, Armagh, Down, and Monaghan will have their own sanatoria. Twenty-three counties are contracting for accommodation (including arrangements of a provisional character) for their own patients in other institutions. The sanatoria in Dublin county borough and county, Cork county borough and county, and Clare county are in full working order. As regards the number of beds provided, the figures (including institutions in contemplation) are: county institutions, 932 beds; contracted beds, 270.

Mr. LARDNER asked the honourable Member for St. George's-in-the-East whether any councils of counties or county boroughs in Ireland had agreed to pay half of any expenditure on the treatment of tuberculous insured persons over and above the money provided for sanatorium treatment under the National Health Insurance Act, if so, would he give the names of such authorities; would he state whether any Insurance Committees had represented to the council of their county or to the Treasury that the amount available for defraying the cost of sanatorium treatment to insured persons resident within their area was already, or was likely to be, insufficient to meet the estimated expenditure; if so, would he give the names; whether any grants under Section 17 had been made in Ireland; and, if so, would he state the amounts and the authorities to whom made.—Mr. WEDGWOOD BENN answered: Up to the present time one county council in Ireland—namely, Meath—has agreed to meet one-half of the anticipated deficiency under Section 17. The other half will be met by the Treasury in due course.

Declarations of Conscientious Objection to Vaccination.

Mr. YEO asked the President of the Local Government Board whether his attention had been called to the fact that owing to the somewhat confusing wording of the vaccination schedule which was given to parents at the time of registering the births of their children, and also on Form Q issued by vaccination officers, many parents were led to suppose they could make a declaration of conscientious objection to vaccination within four months and seven days of the birth of a child; and whether he could see his way to have the schedules and forms in question so altered as to make it unmistakable to parents that they must make their declarations within four months of the birth of their children.—Mr. HERBERT SAMUEL replied: I am aware that difficulties have arisen and I am taking steps to obviate them.

Special Nourishment for Tuberculous Patients.

Mr. CAWLEY asked the honourable Member for St. George's-in-the-East whether District Insurance Committees had power at their own discretion to allow special nourishment to tuberculous persons discharged from sanatoria, or whether such nourishment could only be allowed when a tuberculosis officer recommended it for assisting the restoration of working capacity in other than hopeless cases.—Mr. WEDGWOOD BENN wrote in reply: The powers and duties of District Insurance Committees in connexion with the administration of sanatorium benefit are determined by the scheme adopted for the area in accordance with Section 59 of the National Insurance Act, 1911, and the Regulations made thereunder. Generally speaking, accessories in the form of special nourishment may be afforded to insured persons in receipt of domiciliary treatment where recommended on medical grounds. As the honourable Member is aware, however, it is the duty of the Insurance Committee to provide treatment and not to relieve destitution.

MONDAY, APRIL 6TH.

A Milk Substitute.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether he was aware that it was proposed to sell as milk, in London and elsewhere, a liquid prepared from a species of soya bean, having the appearance and, to some extent, the flavour of cow's milk, but not possessing its nutritive or other qualities; whether the Board had powers and, if so, under what statute, to prevent the sale of such a product under the misleading denomination of milk; and, if so, whether it was proposed to exercise such powers.—Mr. HERBERT SAMUEL replied: I am aware of the product to which the honourable Member refers, but I am not prepared to express an opinion as to its nutritive qualities. If an article which is not milk is sold under that name it would be open to local authorities to take proceedings under the Sale of Food and Drugs Act against the vendor.

Treatment for Tuberculosis in Dependents of Insured Persons.

Mr. ASTOR asked the President of the Local Government Board whether a dependent of an insured person, who was treated for tuberculosis by a local authority undertaking treatment of tuberculosis for the whole population with the aid of the Hobhouse grant from the Treasury, was entitled to the same domiciliary treatment as might be given if sanatorium benefit was extended under Clause 17 of the National Insurance Act to dependents of insured persons.—Mr. HERBERT SAMUEL answered: Dependents are not entitled as a right to domiciliary treatment even if an Insurance Committee has extended sanatorium benefit to such persons. The matter is within the discretion of the Insurance Committee. Local authorities generally have not so far included domiciliary treatment in their schemes. The view that has been acted on is that the institutional side of these schemes should be fully developed before the question of providing domiciliary treatment is considered.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CRAIG, EFFIE M. D., M.B., Ch.B.Edin., has been appointed Assistant Medical Officer of Health of Birmingham.

HARBOROW, GERALD, L.D.S. R.C.S. Eng., has been appointed Dental Surgeon to the Metropolitan Hospital, Kingsland-road.

STEEL, RUSSELL V., M.B., B.S. Durh., has been appointed House Surgeon at the West London Hospital.

THOMSON, RUBY, M.B., Ch.B.Edin., has been appointed School Medical Officer for the County of Stafford.

YORKE, COURTENAY, M.D. Liverp., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Honorary Laryngologist to the Liverpool Hospital for Consumption and Diseases of the Chest.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSLEY, BECKETT HOSPITAL AND DISPENSARY.—Second House Surgeon, unmarried. Salary £100 per annum, with apartments, board, and laundry.

to learn that they had been led for miles by a blind man, they being of the opinion that his eyes only looked a bit queer, as if he had been spirit drinking. A blind man who knows the road well may be a better guide in the dark or fog than a man with eyesight, but Blind Jack seems to have been better by daylight in familiar places than many with the due physical equipment.

DENTAL EDUCATION.

To the Editor of THE LANCET.

SIR,—I wish to draw your attention to two paragraphs which appear in THE LANCET of March 28th. One is on p. 911 and is headed "The Future of Dental Education," and the other appears under "News from Scotland," on p. 923.

Both these paragraphs refer to a meeting of unregistered men, who call themselves the "Incorporated Dental Society." From the publicity given in your journal I am afraid that your readers may have formed the impression that this was a society composed of dentists. I shall, therefore, be glad if you will correct this impression.

I am, Sir, yours faithfully,
FRANK J. PEARCE,
Hon. Secretary British Dental Association.
Hanover-square, London, W., March 31st, 1914.

SLEEPING SICKNESS IN NYASALAND.

Mr. H. Hearsey, principal medical officer in the Nyasaland Protectorate, in Part XXII. of his "Diary," reports that 19 additional cases of sleeping sickness were notified during the four months ending Dec. 31st, 1913: 1 from Marimba district by Dr. Morgan, 2 from Upper Shiré district by Dr. Sanderson, and 16 from the proclaimed area of the Dowa district by Dr. Conran. Six were discovered in September, 4 each in October and November, and 5 in December. These 19 cases bring the total reported up to 172, of which 64 occurred in 1913. The prominent details of the cases are given. The preventive measures in the proclaimed area of the Dowa district are reported to be attended with good results.

COCOANUTS AND COKERNUTS.

To the Editor of THE LANCET.

SIR,—Some years ago I read, I believe it must have been in a Customs tariff book, that the spelling "cokernut" was adopted by the Customs to avoid confusion with "cocoanut." I have tried to get on the track of this statement again, but although I have searched dictionaries and trade-books I cannot rediscover the printed statement which I unfortunately failed to make an exact note of. It seemed to me to be an interesting piece of information which I had not read before, and the dictionaries do not enlighten me. My memory is usually good for such facts, so I do not think that I can have imagined it. A cart passed me in the street last week with the title "Cokernut Merchant" painted on it, which recalled my fruitless search a year ago for the origin of the variant spelling, as also did the cokernut cake which the little boy Starchfield had eaten just previous to his death in the North London railway train.

I am, Sir, yours faithfully,
W. F.
London, April 6th, 1914.

THE MILWARD FUND.

Mr. William Sheen, F.R.C.S., 2, St. Andrew's-crescent, Cardiff, honorary treasurer of this fund, acknowledges a further subscription of £10 from the Blackburn Division of the British Medical Association, per J. Shearer, honorary secretary.

A REPUDIATION.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a publication in the "Parsee" vernacular paper associating my name with intracapsular extraction of cataract. I beg to state that the said article has appeared without my knowledge and consent.—I am, Sir, yours faithfully,

B. P. BANAJI, F.R.C.S.I.,
Ophthalmic Surgeon, Parsee General Hospital.
Fort, March 13th, 1914.

THE SYMBOL ℥.

Mr. Chas. Olley.—The question of the meaning of the symbol ℥ has been raised at frequent intervals. On one hand it has been argued that it signified the avoirdupois ounce of 437½ grains, and on the other that it signified the apothecaries' ounce of 480 grains. But there can be no doubt, in our opinion, that it stands for the apothecaries' ounce. In the *Pharmaceutical Journal* of Dec. 15th, 1877 (p. 477), Professor Redwood explained the legal position of the question, and his explanation left no doubt whatever that ℥i. means 480 grains. Professor Redwood's view was supported by a member of the Pharmacopœia Committee of the General Medical Council to whom he submitted his statement.

A BURLESQUE insurance policy for the benefit of its subscribers, printed in the March number of the *St. Thomas's Hospital Gazette*, will, we think, add to the reputation for wit and high spirits which this students' journal has built up during recent years. It is delightfully funny without being offensive.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 13th and 14th (Berlin).—Thirteenth Congress of the German Orthopædic Society.
,, 13th–16th (New York).—Fourth Congress of the International Surgical Society. (*President: Prof. Depage, Bruxelles.*)
,, 15th–18th (Berlin).—Forty-third Congress of the German Surgical Society.
,, 19th–21st (Berlin).—"Jubilee" Congress of the German Röntgen Society.
,, 20th–23rd (Wiesbaden).—Thirty-first German Congress for Internal Medicine.
,, 27th–May 1st (London, Royal Horticultural Hall).—Nursing Conference and Exhibition.
May 1st–Nov. 1st (Lyons).—International Town Hygiene Exhibition.
,, 15th–Oct. 15th (Berne).—Swiss National Exhibition.
May (London, Imperial Institute).—Victoria League Imperial Health Conference.
May-October (London, Shepherd's Bush).—Anglo-American Exposition.
June 8th–10th (Berne).—Seventh International Dairy Congress.
,, 18th–24th (London, Church House, Westminster).—International Conference on the Blind.
June–July (Groningen).—University of Groningen 300th Anniversary Celebration.
July 6th–11th (Blackpool).—Twenty-ninth Congress of the Royal Sanitary Institute.
,, 8th–10th (Oxford).—Ophthalmological Congress.
,, 8th–13th (Edinburgh).—Congress of the Royal Institute of Public Health.
,, 21st–23rd (Chester).—British Pharmaceutical Conference.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY.
SECTION OF DERMATOLOGY (Hon. Secretaries—J. M. H. MacLeod, S. E. Dore): at 4.30 P.M.

Cases:
Dr. Graham Little: (1) Pityriasis Rubra Pilaris; (2) Von Recklinghausen's Disease with General Analgesia.
Dr. Pernet: Double Primary Chancre of the Lips in a Man.
Dr. W. Knowsley Sibley: Nævus Araneus.

FRIDAY.
SECTION OF OTOLOGY (Hon. Secretaries—G. J. Jenkins, W. M. Mollison): at 5 P.M.

Cases and Specimens:
Will be shown by Mr. H. L. Whale, Mr. G. J. Jenkins, and others.

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—Cecil R. C. Lyster, S. Gilbert Scott): at 8.30 P.M.

Papers:
Dr. R. W. A. Salmond: Some Experiments on X Ray Filtration.
Dr. Curtis Webb: Electrolysis in the Treatment of Hæmorrhoids.
Dr. C. Russ: The Measurement of Radium Rays as Used Clinically.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY.—5 P.M., Prof. Keith: Specimens illustrating Difficulties in the Diagnosis of Sex. (Museum Demonstration.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women, and Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear, and Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. H. B. Carlill: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.15 P.M., Sir Malcolm Morris: Skin.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. B. Carlill: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. H. R. Prentice: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Mr. C. Rowntree: Cancer of the Rectum.

FRIDAY.—Out-patient Demonstrations;—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford: Medicine. 3.15 P.M., Mr. L. McGavin: Surgery. 2.15 P.M., Special Lecture:—Sir J. Rose Bradford: Dropsy and its Treatment.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. R. Prentice: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

MONDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Cardiac Department, Dr. Stott; Out-patient Department, Dr. Phear, Dr. S. Thompson. 3 P.M., Wards, Dr. Phear.

TUESDAY.—9 A.M., Laryngological Department, Mr. Mant. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. M. Leslie, Dr. B. King; Operations, Mr. A. Evans. 3 P.M., Wards, Dr. White. 4 P.M., Wards, Dr. M. Leslie.

WEDNESDAY.—2 P.M., Wards, Dr. A. Davies; Out-patient Department, Dr. Drysdale, Dr. Kellie. 4 P.M., Wards, Dr. Drysdale. 4.30 P.M., Roentgen Ray Department, Dr. Jordan.

THURSDAY.—9.30 A.M., Dental Department, Mr. G. Thomson. 10 A.M., Cardiac Department, Dr. Stott. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. Phear, Dr. S. Thompson. 4.30 P.M. Laryngological Department, Mr. Mant.

FRIDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Wards, Dr. Calvert; Out-patient Department, Dr. M. Leslie, Dr. B. King. 5 P.M., Lecture-Demonstration:—Mr. Thomson: The Teeth in Relation to Pulmonary Tuberculosis.

SATURDAY.—10 A.M., Out-patient Department, Dr. Drysdale, Dr. Kellie. 11.30 A.M., Roentgen Ray Department, Dr. Jordan.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

LONDON LOCK HOSPITAL, 91, Dean-street, Soho, W.

Special Course of Instruction in Venereal Diseases, for Post-Graduates and Students, with Practical Demonstrations of the Various Methods of Treatment:—

MONDAY.—Clinics:—1 P.M., Mr. Ryall; 6 P.M., Mr. Gibbs.

TUESDAY.—Clinics:—2 P.M., Mr. Lane; 6 P.M., Mr. Paterson.

WEDNESDAY.—Clinic:—6 P.M., Mr. Shillitoe.

FRIDAY.—Lecture:—4 P.M., Mr. McDonagh: The Biology of Syphilis.

SATURDAY.—Clinic:—2 P.M., Mr. McDonagh.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The following journals, magazines, &c., have been received:—Archives Générales de Médecine, Quarterly Journal of Medicine, Journal of Nervous and Mental Disease, Review of Neurology and Psychiatry, Annales de Gynécologie, Dominion Medical Monthly, Journal of Comparative Pathology and Therapeutics, British Journal of Inebriety, Science Progress, Medical Review, Hospital Assistant (India), Indian Medical Journal, British Dental Journal, Clinique Ophthalmologique, Archiv für Schiffs- und Tropen Hygiene, Public Health, Asylum News, West London Medical Journal, South African Nursing Record, Interstate Medical Journal, Caledonian Medical Journal, Pediatrics, Proceedings of the Royal Society of Medicine, Journal of Physiology, Therapeutic Gazette.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Army and Navy Male Nurses' Co-operation, Lond., Secretary of; Dr. A. G. Auld, Lond.; Dr. K. B. Allan, Tovil; Ardath Tobacco Co., Lond.; Dr. H. G. Adamson, Lond.; Mr. E. A. Attwood, Lond.; Messrs. Arnold and Sons, Lond.; American Laryngological Association, New York, Secretary of; Mr. Joseph E. Adams, Lond.; Mr. Osborne Aldis, Lond.; Dr. Armly Ashkenny, Birmingham; Admiralty, Medical Department, Director-General of.

B.—Mr. B. P. Banaji, Calcutta; Messrs. W. H. Bailey and Son, Lond.; Brentford Union Infirmary, Lond., Secretary of; *Board of Agriculture* and Fisheries, Lond., Secretary of; Mr. F. B. J. Baldwin, Bodicote; Bath Royal United Hospital, Secretary of; The Bayer Co., Lond.; British Hospitals Association, Lond., Hon. Secretaries of; Messrs. Bennett Bros., Salisbury; Bedford County Hospital, Secretary of; Bristol Royal Hospital for Sick Children, &c., Secretary of.

C.—Mr. R. de Cordova, Lond.; Dr. L. G. Cole, New York; Mr. James S. Collis, Lond.; Messrs. Cleaver and Co., Lond.; Carlisle Corporation, Clerk to the; Mr. H. Cripps, Lond.; Mr. H. A. Collins, Croydon; Messrs. Corbyn, Stacey, and Co., Lond.; Messrs. C. Clayton, Lond.; Messrs. Crossley and Co., Lond.; County Borough of West Hartlepool, Secretary of; Cheltenham General Hospital, Secretary of; Messrs. E. Cook and Co., Lond.; Caxton Engineering, Ltd., Lond.; Dr. J. F. Corson, Lorha; Cannon Iron Foundries, Ltd., Bilston.

D.—Mr. J. Davis, Lond.; Messrs. A. Driver and Sons, *Chelmsford*; Dr. Isodore Dyer, New Orleans; Surgeon-General J. J. Dennis, R.N., Haslar; *Professor* A. S. Delépine, Manchester; Messrs. S. Davis and Co., Lond.; Professor Henry R. Dean, Thurlestone Sands; Derbyshire County Council, Derby, Chief Medical Officer of; Durham County Council, Medical Officer of Health to the; Dr. H. B. Day, Cairo.

E.—*Eugenics Education Society*, Lond., Hon. Secretary of; East Sussex Hospital, Hastings, Secretary of; Dr. G. N. Edmondson, Barnsley; Equitable Life Assurance Society, Lond.; Messrs. Elliott, Son, and Boyton, Lond.; Dr. Elmer, Buenos Aires; Mr. F. Kincaid Etlinger, Wokingham; Mr. T. S. Elliot, Southwell.

F.—*Dr. Ernest* E. Francis, Chittagong; Fuller Accumulator Co., Lond.; Messrs. S. Flavel and Co., Lond.; Messrs. Fletcher, Russell, and Co., Lond.; Factories, Chief Inspector of, Lond.

G.—Dr. F. W. Gunn, Acklington; Dr. G. T. Gossard, Loraine; Mr. H. Ginn, Worcester; Dr. D. Gault, Auckland, New Zealand; Gas Light and Coke Co., Lond.; Messrs. W. and A. Gilbey, Lond.; Dr. J. G. Gordon-Munn, Norwich; Dr. James Gardner, Burnley; Dr. E. B. Gunson, Lond.

H.—Dr. C. *L. Herman*, Vienna; Mr. L. Hill, Lond.; Messrs. Haasenstein and Vogler, Lond.; Mr. Charles T. W. Hirsch, Lond.; Dr. F. Gowland Hopkins, Cambridge; Hunterian Society, Lond., Hon. Secretaries of; Messrs. Heppell and Co., Lond.; Mr. F. J. Hyam, Lond.; Messrs. C. J. Hewlett and Son, Lond.; *Home of Compassion*, Thames Ditton, Secretary of; Home and Infirmary for Sick Children, Lond.; Dr. Philip A. Harry, Rochdale.

I.—Institute of Hygiene, Lond., Director and Secretary of; International News Co., Lond.

J.—Dr. C. S. Jaffé, Lond.; J. R. C.; Mr. H. W. Jackson, Lond.; Dr. Geoffrey Jefferson, Victoria, British Columbia; Mr. Herbert Jones, Hereford; J. P. H.

K.—Dr. O. Kraus, Vienna; Kirkmabreck Parish Council, Creetown, Clerk to the; Messrs. R. A. Knight and Co., Lond.; Messrs. Kutnow and Co. Lond.; Messrs. Knoll and Co., Lond.

L.—Mr. E. Le Francois, *Paris*; Sir H. B. Longhurst, Hampton Hill; Mr. E. Leitz, Lond.; Dr. Paul Lissmann, Munich; Mr. A. W. Lemarchand, Barnstaple; Mr. H. K. Lewis, Lond.; Mr. N. Y. Lonergan, Camborne; Leicester Royal Infirmary, Secretary of; Mr. F. S. Lister, Johannesburg; Leeds Maternity Hospital; Secretary of; Liverpool Medical Institution, Secretary of.

M.—Mr. R. Mosse, Berlin; Messrs. C. Mitchell and Co., Lond.; Maltine Manufacturing Co., Lond.; Mr. J. Murray, Lond.; Dr. H. D. McCulloch, *Lond.*; Mr. H. J. Monson, Lond.; Margate, Town Clerk of; Manchester Royal Infirmary, Secretary of; Mr. A. A. McConnell, Dublin; Dr. H. W. Mills, San Bernardino; Dr. W. Campbell McDonnell, Lond.; Margate Chamber of Commerce, Secretary of; Mr. W. J. Midelton, Bournemouth; Medical Sickness and Accident Society, Lond., Secretary of.

N.—Norfolk Education Committee, Norwich, Secretary of; North Staffs Infirmary, Hartshill, Secretary of; Nottingham General Hospital, Secretary of; National Society of *Day-Nurseries, Lond.*, Secretary of; Dr. W. Gifford Nash, Belfast.

O.—Messrs. *Osborne, Peacock Co.*, Manchester; Oxford Medical Publications, Lond.; Ozonair, Lond., Secretary of; Mr. J. Offord, Lond.; Mr. J. O'Doherty, Belfast.

P.—Portsmouth Borough Asylum, Clerk to the; Pembrokeshire Education Authority, Haverfordwest, Senior Medical Officer of.

Q.—Mr. A. E. Quine, Sheffield; Queen's University, Belfast, Secretary of.

R.—Royal Institute of Public Health, Lond., Secretary of; Richmond Gas Stove, Ltd., Lond.; Royal Victoria Infirmary, Newcastle-on-Tyne, Secretary of; Royal College of Surgeons of England, Lond., Secretary of; Dr. J. T. Richards, Lond.; Lieu*tenant-Colonel Ernest Roberts*, I.M.S., Lond.; Professor Dr. Lydia Rabinowitsch, Berlin; Dr. A. Maitland Ramsay, Glasgow.

S.—Mr. Frank St. J. Steadman, Lond.; Solly Tuberculosis Society, Colorado Springs, Secretary of; Messrs. G. Street and Co., Lond.; Saccharin Corporation, Lond.; St. Peter's Hospital for Stone, Lond.; St. Anne's-*on*-the-Sea, Medical Officer of Health of; South African Institute for Medical Research, Johannesburg; Mr. Spencer Sheill, Dublin; *Staffs Sentinel* Advertisement Bureau Hanley; Dr. Frank Shufflebotham, Newcastle-under-Lyme; Dr. J. A. Shaw-Mackenzie, Lond.; Dr. Hubert Shield, Newcastle-on-Tyne.

T.—Mr. B. A. Tahawy, Minia; The Turco-British Cigarette Syndicate, Lond.; Dr. Frederick Taylor, Lond.; Tunbridge Wells General Hospital, Secretary of; Messrs. W. Thacker and Co., Lond.; Messrs. Tindall and Jarrold, Chelmsford.

U.—University of Glasgow, Registrar of.

V.—Victoria *Infirmary*, Glasgow, Secretary of.

W.—Walsall and District Hospital, Walsall, Secretary of; Wolverhampton Education Committee, Secretary to the; Westinghouse Cooper Hewitt Co., Lond.; Dr. *Chalmers Watson*, Edinburgh; Messrs. J. Wright and Co., Birmingham; Messrs. H. R. Williams and Co., Lond.; Mr. Harold L. Whale, Lond.; Dr. J. S. Warrack, Gravesend; Weston-super-Mare, Medical Officer of Health of; Mr. Arthur E. Williams, Lond.; Dr. J. A. Watson, Port Morant; Messrs. W. Whiteley, Lond.; Messrs. J. *Williams and Son*, Bradford; West Riding Asylum, Menston, Leeds, Medical Superintendent of; Wolverhampton General Hospital, Secretary of; Dr. R. Stenhouse Williams, Reading; Mrs. P. Warner, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. F. S. Arnold, Bovingdon; A. B.; A. C. D.; Apollinaris *Co., Lond.*; Dr. K. B. Allan, Lond.

B.—Mr. J. B. Brash, Birmingham; Mr. J. C. Barker, Watford; Dr. R. H. Bellwood, Nottingham; Dr. P. H. Bahr, Lond.; Burnley Guardians, Clerk to the; *Messrs. T. B. Browne, Lond.*; Messrs. J. A Clinical Lecture

ON

GANGRENE OF THE LUNG.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton, on Feb. 11th, 1914.

By H. BATTY SHAW, M.D. Lond., F.R.C.P. Lond.,

PHYSICIAN TO THE HOSPITAL AND TO UNIVERSITY COLLEGE HOSPITAL.

Gentlemen,—You will probably have asked yourselves what is the reason which has prompted me to give a lecture on such a comparative rarity as gangrene of the lung—on a disease which Eichhorst has found to occur in only 34 out of 27,472 cases coming under his clinical observation —i.e., in less than 0·1 per cent. Hensel, speaking from post-mortem experience, found it in only 83 cases out of a total of 5072 examinations—i.e., about 1·6 per cent. The answer is that until I came to study cases in the wards of this hospital I had included all cases of pulmonary disease associated with offensive expectoration under the heading of probable cases of bronchiectasis. It was not long before I had a sharp lesson as to how far post-mortem opinion may differ from a clinical one. Lastly, gangrene of the lung is a very serious malady: for, according to Lenhartz, 80 per cent. of the cases treated by medical measures die, and according to Eichhorst a smaller, but still large percentage die—viz., 53 per cent.

The sharp lesson to which I have referred came to me shortly after taking charge of beds in this hospital.

A married woman, aged 24, was admitted with a history of left-sided pleurisy eight months previously, followed by cough and hæmoptysis two months later. The cough was increased by stooping and was accompanied by night sweats; the expectoration was yellow, and occasionally very offensive throughout the six months prior to her admission. Rhonchi were heard over both sides of the chest, fine crepitations at the right apex in front, and a few friction sounds to the right of the pericardium. Six weeks after admission dulness was found at the left base, and in the same situation were some friction sounds. There were no signs of excavation anywhere, nor were tubercle bacilli discoverable in the expectoration. As the phlegm was very copious and very offensive and the fingers clubbed, and as the history of lung mischief extended over a period of nine and a half months and the expectoration of offensive sputum over seven and a half months, it seemed to me that in accordance with my out-patient practice (uncontrolled by post-mortem observation) I might reasonably believe that she was suffering from bronchiectasis, and that the cavities formed by the dilated bronchioles did not reveal themselves because they were charged with expectoration—an occurrence well known to take place in true cases of bronchiectasis. She was accordingly treated, amongst other methods, by elevating the foot of the bed so that the head was depressed, with the idea of assisting the bronchiectatic cavities to empty more easily. The result, whether post or propter, was most disastrous, for in a few days the temperature became much elevated, there was severe toxæmia, and very acute bronchitis was added to her former disabilities. These unfavourable phenomena increased and the patient died. At the post-mortem examination a patch of gangrene as big as half a hen's egg was found at the apex of the right lung, and the left lung was consolidated in its upper lobe and showed numerous small foci of suppuration and small abscesses and bronchitis in the lower lobe; there was also patchy pneumonia of the right lung. There was no trace of bronchiectasis.

Such an experience gives much food for reflection: first of all, because it is quite possible that the treatment hastened, if it did not actually cause death; and secondly, because it looks as if gangrene existed in this case for at least seven and a half months. Another case, happily alive and apparently recovered, thanks to Mr. Stanley Boyd's operation, had gangrene for over a year.

Definition.

To define what is meant by gangrene of the lung, or as it is sometimes called gangrenous pneumonia, is not a simple affair. Gangrene is another name for necrosis or sphacelation, but just as gangrene of the leg may be accompanied by no odour whatever, so gangrene of the lung may exist and yet the expectoration, if present, may be quite free from offensive odour: at a post-mortem examination gangrene may be found affecting the centre of a pneumonic lung. Gangrene of the lung has been met with post mortem, and yet during life the patient not only had no offensive expectoration, but no expectoration at all. At the bedside we must think of gangrene of the lung when we observe, in a case revealing or not physical signs of disease in the lungs, that there is a *sudden* development of horribly offensive expectoration, more offensive than that of bronchiectasis or of abscess of the lung. At post-mortem examinations gangrene may be met with, associated *or not* with offensive odour, but at the bedside we may essay to diagnose but *one* form of gangrene, and that is the offensive one: hence the reason why the qualification "offensive" is omitted, and a clinical diagnosis of gangrene of the lung implies a condition of the lung associated with the expectoration of very offensive sputum.

Causation.

In order to give more sharply the etiology of gangrene of the lung 16 specimens are brought before you from the museums of this hospital and of University College Hospital.

1. The first specimen shows the left lung of a woman, aged 42, who on admission had had chest signs for a year before death and hæmoptysis for the two months prior to death, the last attack proving fatal. The specimen shows no gangrene, but serves to remind us that fatal hæmoptysis may occur in *hydatid of the lung*, and me more particularly of the danger run by a medical friend who for two and a half years has been suffering from signs of lung disease, including hæmoptysis, from infection from this parasite in his lung. The occurrence of offensive expectoration at last forced one to recommend operation, with results which are so far highly satisfactory, and indicate that the gangrenous pneumonia which had probably been set up by his hydatid disease is cured. He had shortly before operation expectorated a large amount of pus (offensive) and hydatid membrane, which has ceased to be expectorated since the operation.

2. The second specimen is the left lung of a patient, aged 63, under the care of the late Dr. Cecil Biss. Gangrene will be seen to exist in the upper lobe, and is represented by an irregular "fluffy" substance stained black by inhaled carbonaceous

PROGNOSIS.

This is unfortunately grave, as from 53 to 80 per cent. of the cases treated by medical measures die. This high mortality is due not only to the gangrene of the lung itself, but also to the fact that gangrene is so often secondary to other grave and irremediable causes.

DIAGNOSIS.

There are no special signs in the chest peculiar to gangrene of the lung. A case of gangrene of the lung may be readily diagnosed from bronchiectasis if under observation throughout the illness which precedes the gangrene, for the sudden onset of the signs and symptoms of gangrene is so different from the more insidious onset in the case of bronchiectasis. Gangrene may last for many months, but bronchiectasis for many years. Clubbing of the digits may develop in gangrene, but the most marked cases of clubbing of the digits are seen in bronchiectasis. The presence of elastic tissue is in favour of gangrene, though its absence does not exclude gangrene. In both bronchiectasis and abscess of the lung there is freer discharge of pus, and in many cases there is a distinct sign of cavity formation. Offensive empyemata may burst into the lung and cause difficulty in diagnosing gangrene, and then an exploratory puncture may be necessary. Radiographic examination of the chest may be of the greatest help in locating the site of the gangrene, but as a means of distinguishing gangrene from conditions simulating it little can be expected. The toxæmia met with in gangrene is much greater than in abscess or bronchiectasis, and, as already noted, it is of much more sudden onset than in bronchiectasis. "Foetor ab ore" as met with in uræmia and pyorrhœa alveolaris may in a case presenting lung signs simulate gangrene of the lung, but an examination of the sputum should be of help in such cases.

TREATMENT.

This constitutes one of the most vexed problems which physicians and surgeons must share with one another. A certain number of cases recover by themselves, but the number is not so great as the recoveries following operation. We have seen that Lenhartz found that of cases not treated by operation only 20 per cent. recover; Eichhorst believes that of such cases 47 per cent. recover. Garré found that of the operated cases 66 per cent. recover, and Lenhartz 64 per cent. From a consideration of these figures operations should be carried out promptly as soon as the case is diagnosed as one of gangrene of the lung and is found suitable for operation. It is interesting to know that adhesion of the parietal to the visceral pleura is found in about 92 per cent. of all cases.

There are, however, some "ifs" which must be attended to and which constitute the real difficulty. As we have seen, primary gangrene of the lung is practically unknown. Careful clinical research and observation are needed to discover the nature of the cause at work which has led to the gangrene. In those cases in which the primary cause is a disease from which recovery may be anticipated—e.g., typhoid fever—there should be little delay in considering the wisdom of operation. But where there is some primary cause which will soon be fatal there would be no point in operating. In view of the fact that some cases do recover spontaneously some delay in operation even in favourable cases is advisable; the question is, how long a delay should be recommended? It is useless to try to find a limit from the study of cases of recovery. It is much more reasonable to be guided in each case by the behaviour of the signs and symptoms. If the patient is rapidly losing ground delay in operation should be discountenanced, unless indeed when operation is considered inadvisable by the surgeon on account of the severe symptoms. On the other hand, if the symptoms are not increasing, time should elapse before an operation is decided on.

A point of considerable interest which I have observed is this, that though successful pneumotomy is a difficult proceeding in some cases, owing to the difficulties in finding the site of the gangrene, yet considerable relief is given to the patient by the drainage of the adjacent lung by the pneumotomy wound, even if the gangrenous area is not reached. Further, it is preferable for the offensive discharge to escape through a wound in the chest than to be expectorated.

The medical measures for the cure of gangrene are small in the extreme. All that can be hoped for is to treat the patient symptomatically and to endeavour to lessen the offensiveness of the expectoration and breath by the use of creasote and other allied remedies both by internal administration, by the mouth, by inhalation, or by intrabronchial application. Rest in bed is to be recommended because it is easier then to bring up the foul expectoration from the seat of the malady. Hæmoptysis may be checked by the use of calcium salts or by the inhalation of turpentine. Operation is most likely to be successful in cases of gangrene due to pneumonia or embolism—generally speaking, in cases in which the gangrene is localised. The unfavourable cases are those in which the gangrene is widely diffused, cases dependent upon bronchiectasis, or cases following the aspiration of food.

CENTRAL MIDWIVES BOARD.—Special meetings of the Central Midwives Board were held at Caxton House, Westminster, on March 30th and 31st, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges, amongst others, having been brought forward: Neglecting to take the temperature of the patient, as required by Rule E. 13; employing an uncertified person as a substitute, in contravention of Section 1 (4) of the Midwives Act, 1902; neglect to wash the patient on the termination of labour, as required by Rule E. 7 (b); not adopting the antiseptic precautions required by Rules E. 3 and 7; not keeping a register of cases, as required by Rule E. 23. A child suffering from inflammation of and discharge from the eyes on and after the third day the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20 (5); falsely recording in the register fictitious entries of the temperature of the patients; not possessing the whole of the appliances or antiseptics prescribed by the rules; neglect to send notification to the local supervising authority of the occasions upon which medical aid is sought for patients; tying the cord negligently and carelessly so as to endanger the life of the child; not wearing a skirt of washable material when attending patients, as required by Rule E. 1; having been in contact with a person suffering from puerperal fever attending as a midwife at confinements without having undergone disinfection of self or clothing to the satisfaction of the local supervising authority, as required by Rule E. 5; and not being scrupulously clean, as required by Rule E. 1.

The Arris and Gale Lectures
ON
THE MORPHOLOGY OF THE EXTERNAL GENITALIA OF THE MAMMALS.

Delivered at the Royal College of Surgeons of England on March 4th and 6th, 1914,

BY FREDERIC WOOD JONES, D.Sc. LOND.,
LECTURER TO, AND HEAD OF ANATOMICAL DEPARTMENT AT, THE LONDON SCHOOL OF MEDICINE FOR WOMEN.

LECTURE II.[1]

Delivered on March 6th.

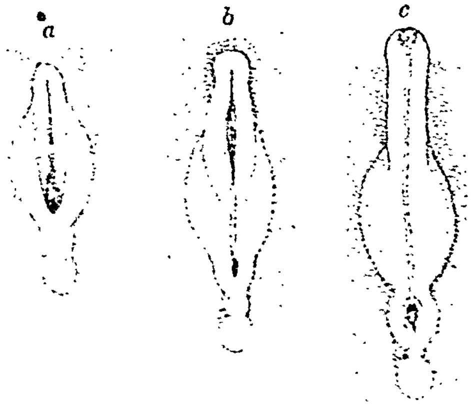
MR. PRESIDENT, LADIES, AND GENTLEMEN.—I will first deal with the developmental phases of the type which, since it will be better to treat it detached from specific examples, I will designate as Type A. In this type the dominant factor in the evolution of the adult condition is the extroversion of the cloaca.

DEVELOPMENTAL PHASES.

Type A: Male.

In the male of Type A the intracloacal genital tubercle is well developed and possesses all the characteristics described in the chelonian penis. The terminal part, which is ultimately to become the glans penis, is not invaded by the seminal groove, although upon the remainder of the penis this groove is well marked as far back as its termination behind the cloacal orifice of the uro-genital sinus. Upon either side of the seminal groove the seminal guides (now called the inner genital folds) are well developed, and they run from the anterior extremity of the seminal groove at the base of the glans to the cloacal orifice of the uro-genital sinus, and past it to the anus, so that, as in the chelonian, they merit the anatomical name of plicæ recto-urethrales. Around the opening of the cloaca run the pouting cloacal lips. (Fig. 8.)

FIG. 8.



The stages in the development of the male of Type A. In (a) the cloacal lips (outer genital folds) surround the partly intracloacal genital tubercle which presents a well-marked seminal groove and well developed seminal guides (inner genital folds). In (b) the genital tubercle is extroverted and the seminal guides are fusing. In (c) the seminal guides have fused and formed the raphé and the cloaca is obliterated. (Figured from developmental phases in *Homo*.)

The next phase in development is the elongation of the genital tubercle and its complete eversion from the cloaca, accompanied by a general shallowing of the cloacal cavity by the sinking of its roof towards the surface of the body. By a continuation of this process the cloaca, as a cavity, becomes practically obliterated, and the visceral orifices that originally opened into it come to be situated on the general surface of the body. With complete eversion of the cloaca the genital tubercle (penis) becomes fully exposed upon the "perineum," and the seminal guides (inner genital folds) begin to close together and meet in the midline, thus converting the seminal groove into a tunnel (penile urethra) by the formation of the median raphé.

Since the seminal guides meet and fuse in the whole of their length, the median raphé extends from the base of the glans penis along the whole length of the penis and into the margin of the anus. This is an important point to note. It is also obvious that with the closing of the seminal groove a channel is formed from the uro-genital sinus to the base of the glans penis, but at this point the channel ceases. It is now that the terminal epithelial ingrowth invades the glans and establishes the continuity of the seminal tunnel (penile urethra) and the terminal orifice in the glans at the fossa navicularis. This epithelial ingrowth is also concerned in delimiting that hood which, present as a fold in the chelonian, becomes the prepuce in the males of this type. This process of preputial formation has been described by Berry Hart and by myself in previous papers.

Meanwhile, with the eversion of the cloaca the prominent cloacal lips have been displaced laterally. These lips pass immediately in front of the free portion of the penis as it becomes everted from the cloaca, and then, skirting along the sides of the cloaca, pass backwards around the anus to meet behind it towards the base of the tail. The cloacal lips, or the special part of them that lies immediately lateral to the sides of the genital tubercle, become prominent and form two swellings upon the perineal surface. These swellings fade away and meet in front of the penis, they swell out and become conspicuous laterally at its base, and they diminish behind at the sides of the anus, becoming lost in the anococcygeal region. It appears to me that these cloacal lips constitute the basis of the swellings that are generally known as the labio-scrotal or outer genital folds.

Type A: Female.

In the female of Type A the intracloacal genital tubercle is small and resembles the female organ of the chelonian. The terminal glans area is differentiated as in the male; but the seminal groove is shallow and not well marked. The seminal guides when compared with the same structures in the male are trivial, and, as in the female chelonian, they do not extend back beyond the orifice of the uro-genital sinus. These reduced seminal guides (inner genital folds) become in the female the labia minora, and it is essential to regard these at the outset as being far from female perquisites, but rather as reduced and almost functionless remnants of functional male structures. (Fig. 9.)

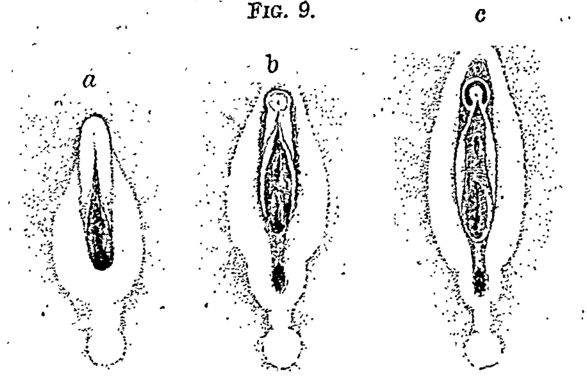
With the eversion of the cloaca in the female the reduced genital tubercle is unfolded upon the perineal surface as the clitoris; the practically functionless seminal guides do not unite over the reduced geminal groove. but stand aside as the labia minora; the prepuce progresses but little further than the stage seen in the female *Testudo*; and the terminal ingrowth for the seminal (urethral) tunnel in the glans, though it may start to develop, does not typically produce a patent channel through the glans. The cloacal lips encircle the whole perineal area as in the male. They meet in front of the clitoris (anterior commissure), they skirt the sides of the genital tubercle (labia majora), and fade away in the anococcygeal region.

---

[1] Lecture I. was published in THE LANCET of April 11th, p. 1037.

It is important to repeat here and to bear in mind the somewhat changed point of view from which this account regards the morphology of the labia minora in the female. These structures in the female tortoise are obviously the somewhat degenerated representatives of the functional seminal guides of the male. In mammalian females of Type A it is equally apparent that they are in a further reduced and functionless condition, and that they never rival in their extent the similar but functional parts of the male. They do not extend back to the hind gut opening in the female chelonian, and in the mammalian embryo they fall still further short of this point. This is an important fact to realise, and it is one that will have to be reverted to in the descriptions of individual species.

FIG. 9.



The stages in the development of the female of Type A. In (*a*) the condition is practically identical with that seen in the male. In (*b*) the cloaca is becoming more shallow and the genital tubercle shows the widely separated seminal guides (labia minora). In (*c*) the parts have practically assumed their adult condition. (Figured from developmental phases in *Homo*.)

One other point needs explanation and emphasis. If all the changes in the development of Type A are initiated and accompanied by an extroversion of the cloaca, it would seem obvious that the area which we term perineum is, in this type, merely the flattened-out roof of the cloaca; this condition contrasts strongly with that displayed in Mammalia of Type B.

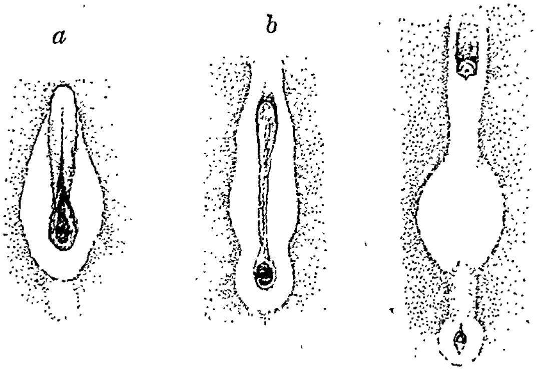
Type B: Male.

The other type which I have come to recognise as being distinct, both by embryonic development and by adult characteristics, I will, in uniformity, designate as Type B. In this type the dominant factor in the evolution of the adult form is the closing over of the cloaca by the cloacal lips—a condition that is altogether different from that described as being characteristic for mammals of Type A.

In the male of Type B the genital tubercle at an early stage possesses all the features described in the chelonian condition, and differs in no essential way from that described in Type A. There is no need to recapitulate these characters, and it is only necessary to follow the stages seen in the embryo in various phases of development. (Fig. 10.)

When the genital tubercle elongates and protrudes from the ventral aspect of the cloaca, the seminal guides close over and meet in the midline, completing the seminal (urethral) tunnel just as in Type A. But in the male of Type B when this seminal tunnel is completed the cloacal lips, or derivatives of a special portion of them, become prominent and also grow inwards towards the midline from either side. This ingrowth of the cloacal margins takes place first at the base of the genital tubercle, and the union in the midline sweeps forwards towards the tip of the genital tubercle until the genital tubercle, with the completed seminal channel (penile urethra), is buried beneath the invading cloacal margins (labio-scrotal folds). In this way the genital tubercle is first everted from the cloaca and then, secondarily, buried beneath the ingrowing cloacal margins. The ingrowth of the cloacal margins first cuts off the hind gut opening from the cloaca, and then, burying the proximal portion of the genital tubercle deeply, it ensheathes the distal portion and binds it to the ventral surface of the body. The whole of the "perineum" in such a case is therefore a derivative of the overgrowing cloacal margins.

FIG. 10.



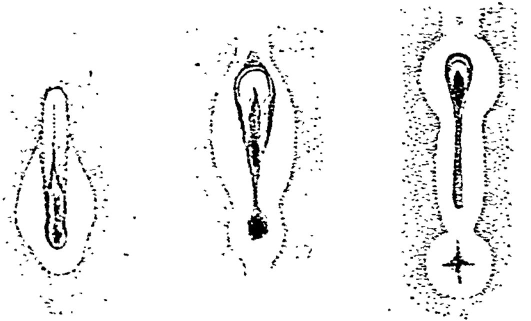
The stages in the development of the male of Type B. In (*a*) the condition is similar to that seen in Type A, but in (*b*) the cloacal margins have begun to grow towards the middle line over the genital tubercle. In (*c*) the genital tubercle is completely ensheathed in the invading labio-scrotal folds. (Figured from developmental phases in *Equus*.)

Type B: Female.

In the female of Type B the genital tubercle is at first similar in all respects to that of the female of Type A, and the seminal guides pass backwards to the opening of the uro-genital sinus. In this type the reduced female genital tubercle is never unfolded from the cloaca upon the perineal surface. The seminal guides remain ununited as the labia minora; but the whole organ is left in a deep recess of the anterior portion of the cloaca by the meeting of the cloacal margins in front of the opening of the rectum. The cloacal margins therefore make the immediate boundary of the uro-genital orifice in the female, and the body of the genital tubercle with its labia minora becomes a deeply situated structure. (Fig. 11.)

It will be readily realised from this description that in embryos of Type B, since the genital tubercle is in both sexes hidden from view within a sheath formed from the cloacal margins, there may be a great similarity between the embryonic stages (and even the adult condition) of males and females. In some animals this similarity of the sexes is very striking, and it is often almost impossible to tell the male from the female when in a fœtal stage. If the genital tubercle of the male is short, or if it is retained deeply within a recess of the ventral portion of the cloaca, the sheath formed by the cloacal margins (labia majora) may be no more prominent than the same part in the female. Again, in the females of many animals which follow this type of development the genital tubercle may be considerably elongated, and except that its seminal guides have failed to unite, it is in all respects similar to the penis of the male. In some quite exceptional instances the stages of development of the two sexes may be absolutely identical, so that in the male and the female both seminal guides (inner genital folds) and cloacal margins (outer genital folds) may meet and fuse over the genital tubercle. These extreme cases will be referred to later. It is to be noted that the similarity between the embryonic stages of the male and female is not present to the same degree in all those animals that fall into Type B. In the Ungulates the likeness between the embryonic stages of the two sexes is nothing like so great as it is in the Rodents, among some members of which order it may be very striking (compare the phases in the fœtal horse and fœtal rabbit).

FIG. 11.



The stages in the development of the female of Type B. The small genital tubercle with its open labia minora becomes buried by the overgrowth of the labio-scrotal folds as in the male. (Figured from developmental phases in *Equus*.)

From these brief descriptions of the main features of the developmental stages in the two types it will be apparent that the adult conditions arrived at will have certain special features which will help to show the line by which the external genitalia were evolved. It would at this stage be too optimistic to hope that a mere examination of the adult external genitalia of both sexes would always suffice to determine, beyond all doubt, in which class, A or B, any given animal should be placed; but, with more extended knowledge, I believe the determination could be done in the great majority of cases with the very greatest certainty. For this reason it is now necessary to outline these adult characteristics imprinted by the two types of development.

ADULT CHARACTERISTICS.

Type A: Male.

The most outstanding feature in males of this type is the complete eversion of the genital tubercle from the cloaca. As a consequence of this process the penis tends to become a free, pendulous organ attached to the perineal surface only by its "root." This character attracted the attention of Linnæus, and partly on the strength of it he included the Cheiroptera among the Primates.

The terminal portion of the penis ends as a glans, which, though it may undergo some slight specific modifications, remains for the most part small in size and simple in its characters. This glans is covered wholly or in part by a simple reduplication of the skin of the penis which constitutes the prepuce. The prepuce may be united to the under (primitive dorsal) aspect of the glans by a frenum which runs to the immediate base of the glans area, and becomes continuous with the most distal part of the united seminal guides. The free pendulous penis being a mere extroverted genital tubercle, and having *only* this intracloacal structure and the seminal guides entering into its composition, is covered, as a rule, by a very fine skin which gives rise either to no, or to few and special, hairs. The raphé, which marks the line of union of the seminal guides, is continued backwards along the penile body and across the penile root towards the anus into the anterior margin of which it extends. This feature is not, as a rule, sufficiently emphasised in descriptions; but in the majority of cases it is a very conspicuous one. In the male human fœtus (as an example of Type A) the passing of the fused seminal guides within the anal margin is very obvious; in the normal human adult the same feature is almost equally striking. This is a curious instance of the perfect retention of a chelonian feature, for in the males of these animals the seminal guides pass right back to become lost only within the lumen of the rectum.

The fine skin of the genital tubercle is the site of the deposition of pigment in most of the representatives of Type A, and in some of them this reaches a very high state of development. Upon either side of the root of this pendulous penis is a very different area—the *area scroti* of Klaatsch—which is derived from the cloacal margins (labio-scrotal folds). The *area scroti* possesses very definite characters, which in many ways are in some contrast to those of the penile area; the skin is somewhat coarser, it rests upon a more dense stratum of subcutaneous tissue, and it gives rise to hairs in greater abundance than does the penile area. Moreover, a remnant of the muscle of the panniculus carnosus generally persists in this area. It is to be noted that the actual testicular sac is not always developed at exactly the same site in the cloacal margin; and, indeed, it may occupy any portion of its length. In males of Type A the scrotal pouches are found in front and to the sides of the genital tubercle (*Tupaia*), at the sides and base (*Homo*), and still further back beside the anus or even behind it (*Cheiroptera*).

Type A: Female.

There are many very distinctive features to be recognised in the female external genitalia formed according to this type. The everted cloacal margins (labio-scrotal folds) may or may not be prominent as labia majora or outer genital folds. The development of these varies greatly in different animals all of which conform to this type of development. Well marked in some of the European races of mankind, they are by no means prominent in some African and some Asiatic races, and in many individuals would hardly merit any description as folds or ridges, being marked only by their skin characters and by the presence of the pubic hair which springs from them. Even the development of pubic hair may be extremely slight in the females of some races which do not practise epilation.

In a large number of other mammals of Type A this minimal development displayed by the human female is the normal condition typical of the adult female. In most of the Primates the labia majora are but little marked, and the presence of specialised hair alone indicates their existence in Cheiroptera.

The clitoris is fully exposed upon the surface of the perineum, and it is subject to considerable

Dr. Robert Wells Library
[illegible] Medical College
[illegible]
1643

variations in size. Typically it is small and terminates in a small glans which is protected by a slight hood (prepuce) which secondarily joins the labia minora. In most cases this glans is solid, and unperforated by the ingrowth which forms the terminal portion of the urethra in the male. In *Myotis nigricans*, and probably in other members of the Cheiroptera, this terminal ingrowth develops, but does not constitute a functional canal. In some of the Lemurs a further development is seen.

The labia minora (seminal guides) diverge from the under side of the clitoris and pass backwards for a variable distance in different animals, and even in individuals representative of the same species. This variability is well displayed in the human female, for though these folds may at times pass backwards so far as to encircle the vaginal orifice, and meet to form a *fourchette*, it is more common for them to disappear altogether behind the urethral orifice at a point about halfway between the ventral and dorsal margins of the opening of the vagina. In some cases, not to be considered as abnormal, they do not extend so far back even as this mid-point. In some animals of Type A they are still more limited, and are practically confined to an area stretching from the under surface of the clitoris to the sides of the urethral orifice. Such a condition is seen in *Perodicticus potto*. In some Lemurs these seminal guides become again of functional importance.

It is to be noted that the body of the human clitoris is normally small, and that it is practically free from any groove upon its lower surface. In most Primates the clitoris reaches a relatively greater degree of development, and the urethral groove is more evident; and in some species the labia minora actually fuse over the groove and complete a urethral, though not a uro-genital, canal. In these animals the genital tubercle may be exactly similar in the two sexes, but the likeness is merely a superficial one, for functionally the two conditions are widely different, since in the male this completed groove forms a continuation of the uro-genital sinus, while in the female it functions as a urinary channel only.

In many of the females of Type A the uro-genital sinus is either altogether absent (the urinary and genital orifices both opening upon the surface of the perineum), or else it is not a very elongated canal. It therefore comes about that the hymen becomes a superficial and easily recognised structure, and this fact has led to the development of the erroneous idea that it is only in such females that the hymen exists.

Type B: Male.

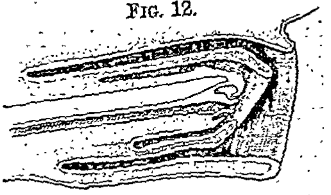
In the male of Type B the most outstanding feature is the incorporation of the penis in the skin of the pubic region. The incorporation may take place over a varying extent in different orders, in some passing as far forwards as the lower portion of the abdominal wall. The penis is no longer free and pendulous, fixed to the perineal surface only by its root, but it is bound down in the whole of its length by an ensheathing fold of the ventral skin. This at the outset constitutes a great contrast to the condition seen in Type A. The degree to which this sheath is carried forwards is, as a general rule, greater in Ungulates than it is in Rodents or in Carnivores; but whatever its extent it is always sufficient to form a complete covering for the penis in all quiescent conditions.

It must be understood that this sheath is developed from the ingrowing cloacal margins (labio-scrotal folds), and that it is therefore a part of the general body skin, or more particularly a portion of that skin in some part of which the *area scroti* is developed. The skin covering the penis in males of this type therefore partakes of the characters of the skin of the scrotal region in males of Type A; it is fairly thick, having some remnant of the panniculus carnosus persisting in it, and it is covered by the same hair that clothes the scrotum and perineum.

The actual site of the scrotal pouches varies somewhat, just as it does in the males of Type A; in some Rodents it is situated almost as far back as it is in the Cheiroptera.

Within the penile sheath the genital tubercle remains hidden. This concealed genital tubercle of course corresponds strictly to the exposed genital tubercle of the males of Type A; but it is subject to a rather wider range of variations. In the first place that portion distinguished as the glans may undergo the most marked, even fantastic, modifications; but it is, as a rule, covered by a prepuce that corresponds strictly to the prepuce developed in Type A. This prepuce is present in many representatives of most orders, but it is not invariably found in such a well-developed state as is usual in the case of the unprotected penis of Type A. This prepuce derived from the genital tubercle must be sharply distinguished from the sheath derived from the cloacal margins. It is a misfortune that the name "prepuce" has been applied without any discrimination to both these structures; even their occasional designation as "primary" and "secondary" prepuces is not a sufficiently distinct nomenclature. (See Fig. 12.)

FIG. 12.



Median section of terminal portion of the penis of a horse (from Sisson). Note the double nature of the "prepuce."

As the penis is traced backwards in its sheath it becomes buried more deeply beneath the tissues of the perineum, and, as a rule, some special development of the penile root is present to ensure full protrusion during functional activity.

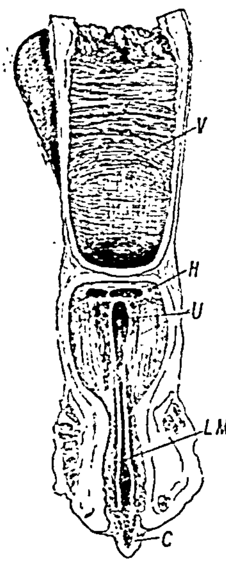
One of the modifications of the adult male condition needs some attention. In some species, especially among the Rodents, the penis sheath may be very short, and the penis so thoroughly concealed within its sheath that it is extremely difficult to distinguish the male from the female unless the genital tubercle can be everted. This condition should be compared to that in those females in which the genital tubercle and its sheath are of unusual length.

Type B: Female.

In the female of this type the cloacal margins surround a recess, which corresponds to the penile sheath of the male, and in which the genital tubercle is similarly hidden. The clitoris and its labia minora (seminal guides) are therefore concealed, and labia majora in some modified form constitute the only margins of the vulva. This vulval recess retains all the characteristics of the ventral part of the female chelonian cloaca.

The open seminal guides (*labia minora*) run upwards on the genital tubercle along the ventral surface of the vulval recess, at the apex of which is the urinary orifice, round the sides of which they pass to disappear upon its dorsal aspect. The hymen in females of this type exists in the virgin condition across the mouth of the utero-vaginal canal wherever this opens into a "uro-genital sinus." Just as the labia minora are concealed in these animals, the hymen itself lies deep within the female passages, and so frequently escapes observation. Nevertheless, all the conditions that are characteristic of the females of Type A could be reproduced simply by everting the vulva of Type B. (See Fig. 13.)

FIG. 13.



Lower end of vagina and uro-genital sinus (vulva) of a young pig. Note the concealed hymen and labia minora. V, Vagina. H, Hymen. U, Urethral opening. LM, Labia minora. C, Clitoris.

Between this vulval orifice, surrounded by its labia majora, and the anus a bridge of tissue exists which constitutes the perineum, but the anatomical basis of this perineum is quite distinct in these animals. In Type A the perineum consists of the extroverted summit of the cloaca, but in females of Type B it is composed of the cloacal margins that have met and united in front of the anus.

We have already seen that in the male of this type the genital tubercle may be so completely concealed, and the sheath be so short, that the likeness to the female may be very great. One other condition remains to be considered. Females of Type A have already been described in which the genital tubercle approaches to a masculine degree of development, so much so that in some Primates it again becomes a urinary canal by the closure and union of the labia minora. Similarly in females of Type B these approximations to the male condition occur, and in some instances are far more profound than anything previously described. In some females of Type B it is not only the urinary, but even the genital canal, that is closed in and carried to the tip of the genital tubercle; in this way the male and female condition becomes exactly similar. In some animals this condition is only temporary; in some, however, it is apparently permanent. [The condition present in the mole, the spotted hyæna, the South American hare, and some other animals was then described.]

UNIVERSITY COLLEGE, LONDON.—The report of this College of the University of London for the year ending February, 1914, which has just been issued, shows that the number of students attending during the session 1912-13 was 2083; of these, 137 attended the department of the faculty of medical sciences. For the year ending August 31st, 1913, the total revenue of the College from all sources amounted to £66,694 2*s.* 8*d.*, being an excess of expenditure over income of £173 10*s.* 4*d.* Among the new buildings that are in progress are a large block for the new chemical laboratories and the building for the purpose of housing the department of applied statistics and eugenics, including the biometric and Galton laboratories. These buildings, however, cannot be completed until adequate funds are forthcoming. The total at present needed to complete the most pressing works in hand is £58,262, of which £43,652 are required for the new chemical laboratories. A special committee, with Prince Arthur of Connaught as President and the Hon. Rupert Guinness as treasurer, is occupied in the task of raising these funds.

INTRASPINOUS TREATMENT (SWIFT-ELLIS) OF GENERAL PARALYSIS:

A PRELIMINARY NOTE ON FOUR CASES TREATED BY THIS METHOD.

BY EDWARD MAPOTHER, M.D. LOND., F.R.C.S. ENG.,

AND

THOMAS BEATON, M.D., B.S. LOND.,

ASSISTANT MEDICAL OFFICERS, LONDON COUNTY ASYLUM, LONG GROVE, EPSOM.

SINCE the description by Swift and Ellis at a meeting of the New York Neurological Society in April, 1913, of a new mode of treatment for parasyphilitic diseases of the nervous system by the injection into the spinal subarachnoid space of salvarsanised serum, a considerable number of such cases have been treated by this method in America,[1] but relatively few have been recorded in this country. The presence of the spirochæta pallida can be demonstrated post mortem in a majority of cases of so-called parasyphilitic diseases of the nervous system, it has been cultivated from the brain tissue of the living general paralytic, and the rabbit has been infected by means of the serum of the general paralytic. These findings indicate that general paralysis is, at any rate in the majority of cases, a true syphilitic process depending upon the presence and activity of the organism itself. The difference between the course of general paralysis and that of other syphilitic lesions of the brain would appear to be due to the different distribution of the organisms in the two cases; in general paralysis they are found in the cortical and subcortical tissue spaces, away from the blood-vessels, and so, inaccessible to the influence of antisyphilitic remedies circulating in the blood stream, hence the failure of the treatment of the disease by intravenous administration of salvarsan as well as by the older antisyphilitic remedies. The cerebro-spinal fluid bears the same relation to the neurone as the lymph to the ordinary tissue of the body, and it is noteworthy that, after the mere introduction of salvarsan into the blood stream, the presence of arsenic in the cerebro-spinal fluid has never been demonstrated, whereas it is especially in that fluid that one finds chemical changes resulting from the altered metabolism of the neurone in general paralysis.

A hopeful line of treatment for this disease would seem, therefore, to be an attempt to destroy the organisms by spirochæticidal substances introduced directly into the cerebro-spinal fluid. The intraspinous injection of salvarsan itself is contraindicated by the meningitis to which it gives rise. It has, however, been demonstrated that the blood serum after intravenous injection of salvarsan possesses a strongly marked destructive action on the spirochæta—this action, in the opinion of most observers, being quite out of proportion to its actual salvarsan content—and such serum can be introduced into the subarachnoid space without any harmful effects. The readiest access for the introduction of the activated serum is afforded by lumbar puncture, this being the method described by Swift and Ellis and also that used by the present authors. Dr. Levaditi, Dr. Marie, and Dr. Martel have modified the procedure by introducing the serum under the cerebral dura through a trephine hole on each side of the skull,[2] the advantage claimed being greater assurance that it should reach the cerebral cortex. However, such heroic surgery would not appear to be necessary as Dr. Cotton, in two cases of general paralysis which died during the course of treatment by the intraspinous method, found salvarsan in the ventricular fluid.[3] It has also been shown that if phthalein be introduced by lumbar puncture into the subarachnoid space, and two hours later fluid is withdrawn simultaneously from the ventricles and through a lumbar puncture, phthalein is to be found in both, though the spinal fluid contains double the proportion found in the ventricular fluid.[4] Further, it was noted by the late Dr. Loomis that after argyrol was introduced into the spinal subarachnoid space it was to be found at necropsy distributed over the cerebral cortex.[5]

---

[1] W. H. Hough and G. W. McCaskey: Journal of the American Medical Association, Jan. 17th, 1914.

The technique of the process as originally described by Swift and Ellis and as carried out by ourselves is briefly as follows. 1. The intravenous injection of 300 c.c. normal saline containing 0·4 grm. salvarsan neutralised with caustic soda. 2. One hour later the removal of 40 c.c. of blood. This is centrifugalised and 12 c.c. of the serum obtained is diluted with 18 c.c. of normal saline, the mixture being then heated for half an hour at 56° C. 3. The intraspinous injection, after removal of an equivalent quantity of cerebro-spinal fluid, of the 30 c.c. of this diluted serum prepared as above. The whole process was repeated four times at intervals of two weeks between Oct. 28th and Dec. 9th, 1913, and a final repetition was carried out on Jan. 5th, 1914.

The Wassermann reaction was quantitatively estimated at Claybury Laboratory in specimens of blood taken before and after the intravenous injection of salvarsan on each occasion, and we may here note that there was never any difference in intensity in the two specimens. A similar estimation with an examination as to the globulin and cell content was performed on samples of cerebro-spinal fluid removed before the intraspinous injection at each sitting. The method used for the estimation of the Wassermann reaction was that devised by Candler and Mann, and shortly to be published in the *Archives of Neurology and Psychiatry*, Vol. VI.

The four patients selected for the treatment were cases showing but a very slight grade of deterioration, as it was felt that if arrest of the disease could be effected the results would be of much greater value if the process of actual destruction of the nervous elements had not preceded very far.

The following is a short summary of the history of each case and of the conditions existing at the time of commencement of treatment.

CASE 1.—A male, aged 40, admitted on June 18th, 1913. Syphilis was admitted 20 years before; no treatment and no secondary symptoms. First symptoms noted two and a half years before, consisting of attacks of vertigo and anxiety, decrease of sexual appetite, and outbursts of intemperance. More recently attacks of confusion with auditory and visual hallucinations, persecutory delusions, and excitement. On admission he was in a confused state with partial amnesia for his recent excited periods, but with considerable insight into their morbid character and distress thereat. There was little genuine dementia, either intellectual or emotional. Before the commencement of treatment he varied considerably, showing at times marked confusion with hallucinations, and occasionally betrayed depression with suicidal tendencies. With regard to physical signs, speech was slow and clipped; the pupils were contracted, unequal, irregular, and both quite immobile to light; all movements were slow; there were tremors of the tongue and the hands; station and gait were both unsteady and the knee-jerks were exaggerated. The Wassermann reaction was strongly positive in blood and cerebro-spinal fluid.

CASE 2.—A male, age 33, admitted July 1st, 1912. Syphilis was admitted 13 years previously; two months' treatment. He had felt dull and anergic for two years before admission, with depression due to quarrels with his wife who drank. On admission he was still depressed, self-accusatory and apprehensive, the result of auditory and visual hallucinations. At the date of commencement of treatment he had improved remarkably, and it was difficult to determine any abnormality, either intellectual or emotional. With regard to physical signs, articulation even of test sentences was normal; the pupils were slightly irregular, rather large, and equal in size; the left reacted very slightly to convergence, the right not at all; both were quite immobile to light. There were marked tremors of the hands, tongue, and face; coördination and sensation were normal; station and gait were normal. There was marked increase of knee and supinator jerks. Wassermann reaction was strongly positive in blood and cerebro-spinal fluid.

CASE 3.—A male, aged 58, admitted on May 31st, 1913. Syphilis was admitted, but the date was not known. The first symptoms were noted 15 months before admission; there was sudden onset of marked amnesia for current events. On admission there were instantaneous amnesia, fabrication, euphoria, complete lack of insight, and tendency to make ill-considered plans for the future. There was little general dementia; he was capable of arithmetical deductions and of a correct and collected account of all events of his past, except those of the previous 15 months. At the time of commencement of treatment he showed practically no change. As to physical signs, speech was a little indistinct in articulation for consonants; the pupils were medium and unequal, the right being larger than the left, and were irregular and inactive to light. There were tremors of the tongue and hands; movement of the limbs was clumsy; station was steady, the gait a little unsteady and spastic; and the knee and supinator jerks were brisk. Wassermann reaction was strongly positive in blood and cerebro-spinal fluid.

CASE 4.—A male, age 52, admitted on August 7th, 1913. Syphilis was denied and physical signs were absent. The first mental symptoms were noted 20 months before. After a fall while at work he developed numerous disconnected delusions, and since then he had done no work and had shown marked confusion from time to time. On admission the mental state varied a good deal. At times he showed no gross intellectual defects, though he was always apathetic and lethargic. There was also a marked incongruity between his apathy and his continual complaints as to his health. No definite delusions could be elicited. From time to time, however, he displayed considerable amnesia for his past life and confusion as to his present surroundings. At the date of commencement of treatment, Oct. 28th, the confusional periods had ceased to occur, there was no amnesia, but he showed a general weakness of judgment. With regard to physical signs, the voice was monotonous, articulation was stumbling and explosive; the pupils were medium, equal, and regular; reaction to light and accommodation was very slight. There were well-marked tremors of the face, tongue, and hands; overaction of the facial muscles and clumsiness of all movements. The ordinary gait was shuffling; he could, however, walk heel-and-toe along a line with little difficulty. There was no Rombergism; the patellar and supinator jerks were very brisk. The Wassermann reaction was strongly positive in the blood and cerebro-spinal fluid.

The reaction immediately following the treatment was slight and diminished in severity with each repetition, the symptoms noted being vomiting, dizziness, slight pain in the head, neck, back, and legs. The occurrence of these, however, was not constant. A rise in temperature, maintained for 30 hours on the first occasion and diminishing in range and duration on each successive occasion, was observed. All four patients exhibited a remarkable similarity in this respect; at no time was the condition of any of them alarming.

---

[2] Levaditi, Marie, and Martel: Comptes Rendus de la Société de Biologie, Dec. 19th, 1913.

[3] W. Cotton: Journal of Nervous and Mental Disease, January, 1914.

[4] W. Swift: Ibid.

[5] Quoted by W. Leszynski: Ibid.

An almost identical reaction, and no lasting change in the patients' condition, followed a set of preliminary experimental procedures on Sept. 26th, 1913. These were designed to test individually the effect of different stages of the treatment, omitting the use of salvarsan, and they were as follows:—Case 1, intravenous injection of 300 c.c. normal saline; Case 2, intraspinous injection of 30 c.c. normal saline; Case 3, intravenous injection of 300 c.c. normal saline and intraspinous injection of 30 c.c. normal saline; Case 4, intravenous injection of 300 c.c. normal saline and intraspinous injection of 30 c.c. diluted serum prepared in a manner similar to that used in the actual treatment.

The changes observed in the conditions of the patients since the commencement of the treatment may be classified under the following heads: (1) changes in the mental state; (2) change in the physical signs of the disease; and (3) changes in the Wassermann reaction.

The changes in the mental state have not been strikingly favourable. Case 1 passed through an attack of hallucinosis, both auditory and visual, without marked clouding of consciousness, immediately following the second repetition of the treatment and lasting about 14 days. Since then he has shown some tendency to euphoria, and though remembering his former hallucinatory periods and recognising their subjective character he is lacking in a correct insight into their gravity. His memory, however, remains good and he is more active and interested in his surroundings. Case 2 remains practically normal. Case 3 shows the same amnesia for current events and of all those since the manifest onset of the disease with the same tendency to fabrication. A few surprising instances of the retention of isolated memories, however, have been noticed. He looks brighter and shows no sign of progressive dementia. In Case 4 the patient's general dulness persists unchanged, without evidence of progressive dementia. Confusional periods, such as were observed previous to the treatment, have not occurred lately.

The changes in the physical signs are as follows. In Case 1 the tremors have entirely disappeared, and the station, gait, and coördination are normal. The pupils are medium in size, equal, regular, and react almost normally in speed and extent. Some analgesia is present. In Case 2 the pupils now both react slowly to convergence and the left only to light; no other change is to be noted. In Case 3, about the beginning of February the pupils were practically normal in form and reactions, but since then have shown a tendency to return to their initial condition. There has been some diminution of tremors and some improvement in coördination. In Case 4 there was a temporary improvement in the condition of the pupils, but this has again disappeared. The tremors are gone and the tendon reflexes are a little less exaggerated.

With regard to the Wassermann tests, the quantitative estimation of the Wassermann reaction in both blood and the cerebro-spinal fluid showed no change whatever: in all cases the reaction in both remains as strongly positive as it was before treatment. The cerebro-spinal fluid in addition was examined for the presence of globulin and excess of cells, and both those conditions were present throughout.

As only five months have elapsed since the date of commencement of treatment, it is obviously impossible to draw definite conclusions. While it is true that in none of the four cases has any progressive deterioration in the mental state occurred, yet it must be remembered that remissions equalling in degree those seen in our patients occur in 7 per cent. to 8 per cent. of general paralytics; moreover, the average duration of such remissions being 11 months, the arrest of progress in our cases is not yet sufficiently prolonged to constitute evidence that the evolution of the disease has been altered.[6]

With reference to the changes in the physical signs, it must be noted that alternating states of the reflex activity of the pupil to light occur in about one-third of cases during the first and second stages of the disease; too much stress, therefore, must not be laid upon such variations as have been observed in our cases.[7] The improvement in the general coördination and the diminution of tremors is only such as commonly accompanies states of remission in the ordinary course of the disease. In our opinion the persistence of the Wassermann reaction in both blood and cerebro-spinal fluid is strong presumptive evidence of the failure of the treatment, for whatever may be the actual genesis of the reaction, it is now generally accepted as indicating the continued presence of the living spirochæta. Furthermore, this persistence of reaction must be due to the presence of the organism under conditions rendering it refractory to salvarsan in the blood stream, and this is characteristic of the disease.

An analysis of cases of general paralysis treated by this method described by other observers, mainly American, shows little ground for the generally hopeful attitude adopted in regard to the treatment, for none of them appear to have produced changes in the mental or physical conditions other than such as are to be seen with almost equal frequency during the untreated course of the disease, and, while in several of the published cases changes in the cell and globulin content of the cerebro-spinal fluid have been noted, in none has any claim been made that the Wassermann reaction has been abolished in either the blood or the cerebro-spinal fluid. Even if disappearance of the Wassermann had been found during treatment, the cure of the disease would be unproven, as periods in which the reaction is temporarily absent have been shown to occur during its ordinary course.

Our thanks are due to Dr. F. W. Mott, the director of the Claybury Laboratory, and to Dr. J. P. Candler, who so kindly carried out the numerous examinations of the specimen fluids on each occasion.

ROYAL INSTITUTION.—On Tuesday next (April 21st), at 3 P.M., Dr. Walter Wahl will deliver the first of two lectures on "Problems of Physical Chemistry"—(1) "Study of Matter at High Pressures," and (2) "Study of Matter at Low Temperature." On Saturday, April 25th, Dr. T. E. Stanton commences a course of two lectures on "Similarity of Motion in Fluids"—(1) "The Theory of Similarity of Motion in Fluids and the Experimental Proof of its Existence," and (2) "The General Law of Surface Friction in Fluid Motion." The Friday evening discourse on April 24th will be delivered by Dr. Frank Watson Dyson, the Astronomer Royal, on "The Stars Around the North Pole," and on May 1st by Mr. E. F. Benson on "A Criticism on Critics."

TONSILS AND ADENOIDS IN CHILDREN:

A PLEA FOR FEWER OPERATIONS.[1]

BY T. B. LAYTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE THROAT AND EAR DEPARTMENT, GUY'S HOSPITAL.

DURING the last year or so discussion has centred so much around the relative values of tonsillotomy and tonsillectomy that we have had no time to consider whether the total number of operations upon the tonsils or for adenoids is more than it should be.

Even though we do not *know* the function of the tonsils, faucial, pharyngeal, and lingual, we have very good reasons to *believe* that these form an early and very important line of resistance to micro-organisms which invade the body through the mouth and nose, and so when we find these organs enlarged we must not at once infer that they are the cause of any surrounding inflammation. It may be that they are enlarged in consequence of it, when our treatment must aim at removing the cause of inflammation rather than at removing the lymphoid tissue which is hypertrophied as a result of it.

I will assume that we are all agreed that the two indications for removing tonsils, faucial or pharyngeal, are because they are the cause of some inflammatory lesion, or because they are causing some mechanical obstruction to the functions of the nose, mouth, or ear. You will probably agree with me that in children the pharyngeal hypertrophy is more important than the faucial, for faucial tonsils have to be very large indeed to cause mechanical trouble to breathing, swallowing, or speaking; further, that the infective sequelæ of the adenoids are dependent upon the mechanical effects of obstruction to the posterior nares or Eustachian tube. In the faucial tonsil we recognise that the flat fibrotic organ with each crypt a bag of pus is the cause of repeated sore-throats and should be removed, but I maintain that these are not common in children, and that the number of tonsils which we see that can definitely be called the cause of sore-throats is small. Now in estimating the degree of obstruction from adenoids or the size of enlarged tonsils we must eliminate two fallacies: we must not come to a conclusion just after an acute attack has got better, nor until any other source of septic infection has been removed. Both these fallacies are, I believe, the cause of a large number of unnecessary operations. A child has a cold, the tonsils are enlarged, and he snores at night; the conclusion is at once made that he suffers from "tonsils and adenoids"; he is seen again at the end of a week, the cold is quite better, the child is well again, but the tonsils are still large, there is still a nasal intonation in the voice, and the operation is performed. If the tonsils be examined critically at this stage it is seen that they are covered with an excess of mucus, that their colour is a redder one than that of the surrounding mucous membrane, and that they have an œdematous appearance distinct from the white, firm look of the true hypertrophied tonsil. If the parents are cross-questioned you learn that the snoring has only been on while the child has the common cold, and that there have been no ear symptoms except during that time. If such a case as that is left for a month while the general health is attended to, a further examination will show in a very large number of cases that the tonsils have become quite small again, and that the adenoid symptoms have entirely disappeared. During this time there will have been time to attend to a common source of sepsis—I mean teeth. I believe that when the rule is made of having all carious teeth in children attended to before an operation on tonsils and adenoids is done, a very large number of these operations is avoided; this is so, both in the cases seen after an acute attack and in those which come up with slight symptoms of snoring and deafness from adenoids associated with enlarged tonsils. The frequency with which one sees all the permanent first molars carious before the child is 10 is a very sad thing: four carious teeth are, I am sure, enough to keep up a chronic pharyngitis which leads to a hypertrophy of the lymphoid tissues of the neck. A personal explanation of how I came to these conclusions may not be out of place at this stage.

Some four or five years ago, when the inspection of school children under the Act of 1907 was being done, but the treatment had not yet been organised, the throat departments of our hospitals were flooded with children returned by the inspectors. So many there were on the books to come into the throat beds at Guy's Hospital that they sometimes had to wait three, four, or five months before admission. During this time we had their teeth attended to; the parents taught them nasal breathing exercises, and we treated any general disorder that needed it. Time and time again, when they were admitted to the hospital, I found that no operation was necessary; sometimes they were sent out again without anything being done; often an anæsthetic was given, and on putting the finger on the nasopharynx no adenoids could be felt. These things taught me definitely that operation is not the only treatment for these conditions, and that in many cases operation was being advised where it was unnecessary. We may consider these things separately.

I have already dwelt upon the importance of carious teeth. I would now impress upon you the importance of breathing exercises. Most people agree that these are valuable; I would say they are essential. I consider that no operation is completed unless these be done regularly and deeply for two or three months afterwards. I believe that in a very large number of cases the operation is unnecessary if they are efficiently done, and that very many operations are useless unless they are done. I admit that it is tiring day after day to tell parents to teach their children to breathe through the nose when you know that in a large number of cases it is never done, but I consider it is wrong to advise an operation unless the parent is told at the time that this operation is only a preliminary, or at any rate only a part of the fuller treatment. If one holds these views as to breathing exercises one sees that it is no argument to perform an operation because the parents will not carry them out.

That dyspepsia of the second dentition which has been called by Dr. Eustace Smith "mucous disease" is another thing to which I would draw your attention. First, some of its symptoms resemble those of adenoids; the cough for which so many children are sent to have their adenoids removed is often the "stomach cough" of our grandparents; the grinding of teeth is often mixed up by careless parents with snoring at night time. Secondly, as a result of the disease the lymphoid tissue all over the body becomes increased, and the pharyngeal and faucial tonsils, which are but masses of lymphoid tissue, are enlarged also. I see no reason, except one of ease, why we should remove these in such a case any more than do a laparotomy and excise one Peyer's patch, or a thoracotomy and cut out the thymus gland. Other observers beside myself have commented upon this relationship between mucous disease and enlarged tonsils, and have said that the removal of the tonsils makes the mucous disease much better; I, on the other hand, find that by treating the mucous disease we can escape in a number of cases the operation with its attendant discomfort and risks, both immediate and remote. How, then, can we decide whether an operation is necessary or not? First, we must have some definite positive indication that the lymphoid tissue present is doing harm, and not operate merely on chance to improve the general health, because it happens to be in excess. Secondly, we must assure ourselves that this is a local disease and not a part of a general lymphoid enlargement all over the body. Thirdly, we must try to decide whether the lymphoid enlargement is a permanent one or merely a transient one due to a recent infection or secondary to carious teeth. Lastly, we must exclude any contraindication which is likely to increase the danger either of operation or of possible sequelæ out of proportion to the advantages we hope to gain.

---

[1] A paper read before the Medical Society of London on March 30th, 1914.

I find some students who work under me talk of operation for tonsils and adenoids as one being devoid of any risk. So far do I disagree with this that I would say that no operation equally small carries with it so many risks. I have never met with one of the cases of severe hæmorrhage which undoubtedly occur, but the list is long enough without them. There is the undoubted risk of the anæsthetic, which is given almost universally in this country. It is useless to deny that children do become almost pulseless when the operation has been done; I ask anyone who has had much experience if he has not had many an anxious moment with these cases? I have had three times to take a patient into the hospital who had been operated upon as an out-patient, and once nearly had to do a tracheotomy for a tonsil that had slipped out of the guillotine and become impacted on the upper opening of the larynx. Further, there is a considerable number of deaths under the anæsthetic with this operation. Dr. B. H. Spilsbury has kindly lent me the manuscript of a paper not yet published in which out of 104 cases of death during anæsthesia six of them were for the operation of "tonsils and adenoids" in children. If we consider only those which have died from the anæsthetic the proportion is higher.

Infection is the cause of the other sequelæ. The least of these is a severe sore-throat which makes the child thoroughly ill for from several days to a fortnight; such a complication is sure to occur in some cases, and it is our business to make these cases as few as possible. Acute otitis media, pneumonia, and metastatic abscesses are the most serious complications. I have seen the first several times; once I saw an acute osteomyelitis of a rib in a child who had had the operation done a week before, and who was suffering from a very severe pharyngitis as a result. The history of the throat beds at Guy's Hospital exemplifies the importance of the second. When the department was first made it was in the hands of an assistant surgeon, Mr. Charters J. Symonds, who took the bigger cases into his own beds, and the "tonsils and adenoids" operations were done in the out-patient department; a series of children had to be taken into the hospital for pneumonia, which resulted in certain beds being set apart for these cases. As the department increased these became throat beds, and again operations were done in the out-patient department. I believe that if cases were more carefully followed up we should find a greater number of instances of pneumonia after the operation. Under the London County Council I am now in charge of one of their clinics attached to the St. George's Dispensary in Southwark. The cases are there followed up by lady clerks of the Council, and if the cases do not return after the operation they are traced to their homes. During the month of September I had two cases of pneumonia occurring after the operations, in neither of which had there been any raised temperature before the operation, nor had there been any acute cold or sore throat for many weeks before the operation; in one case no anæsthetic was given. These cases show that we cannot eliminate post-operative pneumonia as a factor in these operations.

Measles, scarlet fever, and diphtheria may also be looked upon as post-operative complications. I do not mean that the operation causes the acute specific disease, but rather that it is done during the incubation period. If such be the case, it is very obvious that the child runs greater risk during the disease if such an operation has been done just before.

How are we to prevent the occurrence of these acute post-operative inflammations? I find I have had far fewer since I have followed the rule laid down in Professor Killian's clinic, never to operate if the temperature be above 99° F. I believe that in this way you eliminate not only cases sickening for measles and scarlet fever, or many cases likely to get acute otitis or pneumonia, but also that you eliminate cases where the lymphoid enlargement is the result of some temporary inflammation. Everyone agrees that these operations should be done in the quiescent period, the disagreement lying in determining when the quiescent period has arrived.

I do not intend to go into the question of anæsthesia now, but I may say that I find that the bad sore-throat following the operation is much less frequent when no anæsthetic has been given; routine formalin tablets for a few days are also a good thing. Also, I think it is much better to do no operations on out-patients during the winter months. If they cannot be done at home or taken into the hospital for a night or two it is far better that they should wait until the spring than have an anæsthetic, and an hour or so later be sent out with a wound in the throat into a London fog or a drizzle of rain.

In rheumatism and allied conditions the case is different from the other acute fevers. Here, I believe, the operation determines the attack. I have had three cases of attacks of chorea definitely beginning after an operation on the throat; one was most intractable, and kept the child away from school for over six months. The complete removal of the tonsils does not prevent further attacks of rheumatism. In the adult who suffers from slight attacks of pyæmic arthritis which are called "rheumatism," removal of a septic tonsil may cure the attacks, but I do not think it is so in true rheumatism. In January, 1913, I enucleated the tonsils of a girl who had rheumatism, and the operation was followed immediately by another attack, another followed in April, another in June, and another in September. She gets her sore-throat though there is no tonsillar tissue left. "Assuming," said Mr. T. Jefferson Faulder at the Seventeenth International Congress of Medicine, "that the tonsil is the site of infection in rheumatism, &c.": I maintain that we have no right to assume it, and if this is correct there is no more reason for us to remove the tonsil than there is for the general surgeon to do an arthrectomy of the ankle-joint. At the same meeting Mr. Pybus said that he was enucleating tonsils for chorea. So far from enucleating for chorea, in a case where there is any suspicion either of chorea or of true rheumatism, I do not do an operation unless the indications are of the strongest and all other treatment has failed.

I know of no operation in surgery where so much good is so easily done to a patient as when an operation for tonsils and adenoids has been performed in a carefully selected case, and it is for this reason that I think the points that I have brought forward are worthy of consideration; for if we do the operation in unsuitable cases it will needlessly fall into disrepute. But it is not only we specialists who should pause to think whether we are doing too many operations. The general physician, surgeon, and practitioner must also review the position and not imagine that the laryngologist has a panacea for all the ills of a child whose tonsils project beyond the anterior pillar of the fauces. At the International Congress of Medicine Professor Friedreich, of Kiel, and Sir Felix Semon both laid stress on the fact that the pendulum has now swung the other way, that cases often are sent to us for operation on the tonsils to cure all sorts of diseases, and we must strenuously resist such a tendency.

In the light of such thoughts we may consider the cases which return after an operation unrelieved in their symptoms and with the lymphoid tissue grown again. We need not look upon these as being badly or incompletely done, but rather consider whether they were unnecessarily done, or that after-treatment was not done. When such a case comes to me I often find that carious teeth have not been attended to, that no after-treatment has been ordered, or if ordered has been most inefficiently carried out; and I would put it to you that in such cases we should rather stay our hands than believe that because no good has been done a further operation is necessary.

Queen Anne-street, W.

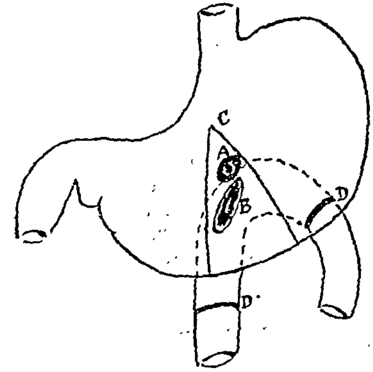
PARTIAL GASTRECTOMY FOR GASTRIC ULCER RECURRING AFTER GASTRO-JEJUNOSTOMY.

BY JOSEPH CUNNING, M.B., B.S. MELB., F.R.C.S. ENG.,
SURGEON TO THE ROYAL FREE HOSPITAL; SURGEON TO THE CANCER HOSPITAL, BROMPTON, S.W.; LATE SURGEON TO THE VICTORIA HOSPITAL FOR SICK CHILDREN, CHELSEA.

THE report of a case of transgastric excision of a gastro-jejunal ulcer by Sir Berkeley Moynihan and Dr. E. T. Tatlow in THE LANCET of March 14th makes me think it may be of interest to record a case in which I had to perform excision of a somewhat similar ulcer, though by a different method.

The patient, aged 38, was admitted to the Royal Free Hospital under my care in 1909 suffering from a perforated gastric ulcer. I opened the abdomen and sutured a perforated gastric ulcer on the anterior wall close to the pyloric end. This so narrowed the pylorus that I considered it advisable to perform gastro-jejunostomy there and then. The patient made an uninterrupted recovery and was completely restored to health, though she had been an invalid for ten years owing to the gastric ulcer. Two years later, however, she got a return of pain after food, which persisted in spite of careful diet and bismuth. Suspecting that she had developed a jejunal ulcer she was advised to undergo a strict "rest and diet" cure for two months. As she was not improved by this I advised her to submit to another operation.

On opening the abdomen I found that so far as the new opening was concerned there was no sign of contraction. (Incidentally, I may state that in no case in which I have reopened the abdomen after gastro-jejunostomy have I ever seen evidence of contraction.) The distal and proximal loops of the jejunum were certainly not the seat of ulceration. On palpating the stomach, however, I discovered that there was an infiltrated area around an ulcer situated on the posterior wall about half an inch superior to the anastomosis opening. I was then faced with the problem of what to do. Here was a patient with a perfect gastro-jejunostomy, supposed to cure gastric ulcer, and therefore still more to prevent its development. Moreover, she was not influenced by medical treatment. Excision of the ulcer thus seemed the only possible hope for her. Situated as the ulcer was, close to the anastomosis, I could not excise it without so interfering with the junction as to render it useless, even if I could have overcome the technical difficulties of such a procedure. The only possibility which occurred to me was to excise the junction and that area of the posterior gastric wall which contained the new ulcer. This involved an excision of a considerable wedge of the stomach and the loop of jejunum which took part in the anastomosis (see figure). The stomach wall was then united by two rows of continuous sutures, beginning above and leaving a sufficient opening below to permit of anastomosing the distal part of the jejunum to it. The short proximal end of the jejunum was then inserted into the side of the distal loop, thus leaving the patient with a Roux's, or Y-shaped, anastomosis. Again the patient made an uninterrupted recovery.



Diagrammatic representation of an ulcer recurring two years after gastro-jejunostomy and the operation of partial gastrectomy, including the anastomosis opening. A, Recurrent ulcer. B, The gastro-jejunostomy. C, The lines of excision of the posterior gastric wall. D, The lines of division of the proximal and distal loops of jejunum.

This operation is rather a formidable one, especially when a no-loop junction has been made and I feel that if I had to deal with a similar condition again I might be tempted to adopt the procedure suggested by Sir Berkeley Moynihan, the transgastric method.

Many years ago I adopted this mode of attack for dealing with hæmorrhage consequent upon the performance of gastro-jejunostomy. In my earlier cases I had two in which post-operative hæmorrhage occurred. I immediately reopened the abdomen, and then made an incision in the anterior wall of the stomach. By means of two fingers on the posterior gastric wall it was simplicity itself to evert the junction through the anterior wound and tie the bleeding point, which in each case was a vessel (probably half divided) at the pyloric end of the wound. Each made a perfect recovery. The method is so simple compared to interfering with the junction from the outside and possibly getting leakage that I should always adopt it if such an accident should occur again. I think it taught me, also, that the most likely reason for hæmorrhage is a largish vessel at the pyloric end, partially divided, and since I have taken special precautions to stitch very closely at that point I have not had a case of hæmorrhage.

The transgastric method of excision of a recurrent ulcer had not seemed to me advisable on account of the difficulty of putting in the peritoneal continuous Lembert suture if the anastomosis had not been previously excised, but Sir Berkeley Moynihan's adoption of a temporary gastrostomy with the tube going into the distal loop of the jejunum apparently overcomes what might appear to be not an ideally water-tight method of union. The lesser severity of the transgastric method, however, appeals to me as possibly the best measure to adopt in most cases.

Upper Wimpole-street, W.

CONTRIBUTION TO THE TREATMENT OF DUODENAL FISTULA;

WITH THE REPORT OF A SUCCESSFUL CASE.

BY CHARLES A. PANNETT, B.Sc., M.D. LOND., F.R.C.S. ENG.,

TEMPORARY SUPERNUMERARY SURGEON TO OUT-PATIENTS, ST. MARY'S HOSPITAL; ASSISTANT SURGEON TO THE ROYAL FREE HOSPITAL.

A YEAR ago a paper was read before the Surgical Section of the Royal Society of Medicine[1] in which a new and simple method for the treatment of perforated gastric and duodenal ulcers was described. It was named by its author "treatment by tamponade." The novelty of this treatment resides in the fact that no attempt is made to suture the perforation: the aperture in the ruptured viscus is merely plugged with a strip of gauze which is allowed to emerge from the abdominal wound. In this paper it was stated that the method had been employed in 15 cases, that no deaths had occurred in this series, and that no fistulæ had resulted. Its originator, after a further trial, has recently[2] again advocated the adoption of this procedure, only, however, citing two cases of ruptured stomach, in one of which a gastric fistula resulted, but healed in ten days.

To discredit the value of the operation in the treatment of perforated gastric ulcers because a fistula occasionally develops after it would be wholly unjustified, unless it could be shown that there do not exist compensatory advantages of greater weight. But in the case of the duodenum no possible advantages could counterbalance the serious drawback of an increased incidence of fistula formation following operation. A gastric fistula frequently closes spontaneously, and even if it never closes life may be maintained for years, as was illustrated in Alexis St. Martin. And this is not altogether exceptional, as the results of gastrostomy for fibrous stricture of the œsophagus have demonstrated. As far as can be ascertained from the writings of the last ten years, a duodenal fistula never heals without surgical aid, and if left is invariably fatal. Moreover, death may be exceedingly rapid. Thus Berg records a death which occurred three days after the establishment of a fistula. Just how frequently a fistula occurs after the suture of a perforated ulcer is difficult to gauge accurately, as there are no statistics available. Such failures are apt to remain unrecorded. The case described here is an example. Struthers[3] refers to 2, Dickie[4] mentions 1, and 2 are described by Berg.[5] Many such must have occurred. But it is probable that the frequency of fistula formation would be greater if no attempt were made to suture the ulcer. Thus in the collective report on perforating duodenal ulcer at Edinburgh[6] there were only 3 fistulæ in 200 cases, and these were the only 3 cases where the ulcer was not sutured. The patients all died in a few days. Recovery from a duodenal fistula, even with adequate surgical treatment, is a rarity. Only 3 cases are to be found in the writings of the last ten years. They were cases treated by Berg,[5] Knaggs,[7] and Souttar.[8] In none of these successful cases was the surgical treatment identical with that pursued in the following case:—

The patient, a thin man, aged 45 years, was admitted to St. Mary's Hospital on Jan. 23rd, 1914. He had a history of an illness of five months' duration. Pain occurred two hours after meals and was relieved by taking food. Occasionally there was vomiting and once there was melæna. Twenty-four hours before admission to hospital the patient was seized with agonising pain in the upper abdomen. Vomiting occurred several times at the onset of the attack and then ceased. The pain had gradually got better and the patient felt so well that he could with difficulty be persuaded that there was anything serious amiss. The abdomen was rigid all over, but muscular spasm was most marked over the upper part of the right rectus. Tenderness, whilst present to some extent all over the abdomen, was most marked over the left upper rectus; the next most tender area was the right iliac fossa. Very unusually, although the recto-vesical pouch of peritoneum bulged, there was no tenderness per rectum. Dulness was present in each flank and in the hypogastrium. The liver dulness was not obliterated. The pulse was 120 and the temperature 98·4° F. The diagnosis of perforated duodenal ulcer was made, and the abdomen was opened through the right rectus muscle. Some free gas escaped. The abdominal cavity was filled with thin purulent fluid. A perforation with a diameter rather less than that of a lead pencil was found in the centre of a large ulcer situated in the anterior wall of the first part of the duodenum. Two Pagenstecher thread sutures were passed through the whole thickness of the edges of the hole and tied. A vertical row of Lembert thread sutures buried the perforation. The closure appeared secure. A gauze drain was carried down to the site of the perforation and a tube inserted into the pelvis. All went well until the fourth day after operation (Jan. 27th), when the gauze emerging from the upper wound was withdrawn. It was followed by a small amount of thin sour discharge. Next day the discharge increased greatly in amount and was bile-stained. After this the discharge of green bile-stained fluid was very profuse. Food was withheld by mouth, an attempt was made unsuccessfully to feed rectally, and glucose and saline injections were administered freely. Milk given by the mouth was seen emerging from the fistula within a few minutes. The rectal washings contained very little fæcal material, and this was pale in colour when the fistula was fully established. On the fourth day after the development of the fistula (Jan. 31st) the condition of the patient was desperate. He lay with sunken cheeks and eyes, his voice was hoarse, his eyesight was failing, and the temperature was subnormal. Emaciation was extreme. He was thought to be dying. The wound was widely gaping, the edges were infected and partly digested by the pancreatic fluid. On this day the abdomen was opened through the left rectus muscle. Crile's anoci-association technique was employed locally. The anæsthetic was ether, and was given in very small quantity. The duodeno-jejunal flexure was identified, and a loop about 8 inches from this drawn out of the wound. The afferent and efferent limbs at the base of this loop were made to communicate by a lateral anastomosis. A rubber catheter was sutured into the efferent limb of the loop according to the technique of Witzel for gastrostomy. The bend of the loop was then sutured to the parietal peritoneum and the wound was closed. On the table 10 ounces of peptonised milk containing a raw egg were poured into the intestine through the catheter. The operation was followed by no shock. Feeding through the jejunostomy opening was performed regularly, and food was also given by mouth. The condition of the patient improved rapidly and the fluid coming from the fistula was rapidly diminished in quantity, so that in ten days' time there was no bile staining to be seen. Next day the jejunostomy tube was removed. No leakage ever took place from the jejunostomy wound. The subsequent course to recovery was interrupted by the development of a parotid abscess which had to be opened twice, but otherwise progress was satisfactory, and the patient left the hospital on March 26th cured.

The problem of the treatment of a duodenal fistula is not a simple one owing to the very slight tendency manifested to spontaneous healing. This is largely due to the fact that in a duodenal fistula practically all the ingested food in addition to the gastric, pancreatic, and biliary secretions escapes. The result is a condition of starvation and consequent grave interference with the reparative powers of the body. Whether the loss of the duodenal secretions themselves plays a part in causing death is open to question. It appears strange that, as in the case here recorded, so much bile should escape from a comparatively small aperture situated at some distance above the opening of the common bile-duct. It would appear as though there were some hindrance to the onward passage of the duodenal contents beyond the opening of the common bile-duct. Ochsner[9] has described a sphincter muscle in this region, and such a muscle contracting would cause the necessary obstruction. It is true that Boothby[10] has denied the anatomical existence of such a muscle, but it seems probable that there is a physiological contraction in this region, for Cannon and Blake[11] have noticed segmentation of the contents of the duodenum after a bismuth feed, and state that food is delayed in the duodenum by circular contractions of the muscular coat. We know, too, that after pylorectomy circular constrictions of the duodenal wall have been proved to take place and to some extent vicariously perform the function of the pylorus. It seems, indeed, that chyme passing through the pylorus is retained in the duodenum before being passed onward into the jejunum until it has been intimately mixed with the duodenal fluids. In such facts may lie the explanation of the profuse loss of bile-stained fluid from a duodenal fistula.

Interest in the treatment of duodenal fistula was first aroused by Berg,[12] who suggested that the correct line to adopt should be gastro-jejunostomy combined with occlusion of the pylorus. This has been accepted by surgeons as the proper procedure. The number of successful cases, however, as stated above, is small. Berg's first case, which occurred after a cholecystenterostomy, was a success, although the patient died from the exhaustion, associated with carcinoma of the pancreas, 17 days later. The discharge from the fistula had ceased. His second case illustrates the futility of suturing the opening in the duodenum to check the outflow of its contents. In this case a fistula occurred seven days after the suture of a perforation. Immediately a posterior gastro-jejunostomy was performed and the ulcer was resutured. Two days later leakage occurred again. Another attempt was made to close the opening in the duodenum when finally the pylorus was occluded, but the patient died next day.

Souttar's case is interesting in that the fistula resulted from the perforation of an ulcer of the duodenum following an extensive burn in a child. Bile and pancreatic juice escaped for nine days. The abdomen was explored, the ulcer found and sutured, posterior gastro-jejunostomy performed, and finally the pylorus infolded. The child recovered. In Knaggs's case gastro-jejunostomy with infolding of the pylorus was successful.

Berg's treatment has the advantage that the gastro-jejunostomy may lead to the permanent healing of an ulcer that would otherwise remain open. It has the disadvantages that an infected area of the abdomen has to be opened up, and that much difficulty may be met with in gaining access to the pylorus through the numerous adhesions. When the pylorus is occluded the amount of bile and pancreatic juice poured into the duodenum is lessened because of the loss of the stimulus of the acid chyme coming through this opening. The consequent diminution in the quantity of fluid discharged from the fistula would at first sight appear to act very advantageously for the closing of the fistula. But a moment's reflection will show that the closing of a fistula, if there is no obstruction to the outlet of the viscus into which the fistula leads, depends scarcely at all upon the amount of escape from the opening. A suprapubic fistula closes when there is no urethral obstruction; a gall-bladder closes when the common duct is open. Failure to close, even when there is no obstruction, however, occurs when the fistulous tract becomes lined with epithelium continuous with that of the surface of the body, or when infection of the wall of the tract cannot be overcome. The closure of a fistula actually depends upon reparative changes in its wall, whereby scar tissue is produced with its tendency to contract and obliterate the channel. The longer the tract is the greater the chance of closure. The duodenum lies high up under the liver, so that the path to the surface is long. In addition the contents of the duodenum contain but few organisms. The tendency to healing would thus seem to be theoretically great. But there are two unfavourable influences: first, the digestive power of the pancreatic juice; and, secondly, the enormous interference with nutrition. If the resources of the body be maintained at as high a level as possible by introducing food into the bowel beyond the duodenum, reparative activity is stimulated and the antitryptic and bacterial defensive powers of the serum are increased. For these reasons the plan adopted in the case here reported seemed to be sufficient. It has the advantages, too, that it is technically a much simpler operation, because there are few or no adhesions to be dealt with; a septic area of the abdomen has not to be opened up; the normal functioning of the pancreas is not interfered with by hindering the formation of the hormone of the pancreas (secretin), which occluding the pylorus does. The disadvantage lies in the fact that a subsequent gastro-jejunostomy, should it become necessary, would be a very difficult and complicated procedure. Nevertheless, I think that this operation will become the method of choice, and Mayo has found that very few perforated duodenal ulcers subsequently need a gastro-jejunostomy.

Devonshire-place, W.

TRAUMATIC DISLOCATION OF THE HIP-JOINT

OCCURRING IN A BOY 10 YEARS OLD.

BY HAROLD RISCHBIETH, M.D., B.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO THE CHILDREN'S HOSPITAL, ADELAIDE, SOUTH AUSTRALIA.

DISLOCATION of the hip-joint of traumatic origin is a very uncommon condition in children. The kind of violence that in the adult produces dislocation must be supposed to produce in children, very much more commonly, separated epiphysis or fracture. As I cannot hear of any such case or find an account of any in the literature,[1] I think the following is worthy of record.

The patient, a boy aged 9 years 9 months, was admitted to the Adelaide Children's Hospital on Jan. 4th, 1914. The history of the accident was as follows. He was sitting on a moving truck filled with clay in a brickyard. He was struck on the left hand by a stone thrown by another boy. He turned and fell off the truck, a height of about 5 feet, and, as he asserts, "turned two somersaults before he hit the ground." The truck, which weighed, according to the father, some 5 cwt., came in contact with the upper and outer part of the boy's left thigh below the great trochanter as he fell. "The truck went half over him." In the boy's fall the first part to strike the ground was the upper and outer portion of the left thigh. He was unable to rise, and his "left leg felt as though it had gone to sleep."

It is thus by no means clear what the exact mechanism of the production of this injury was in the present case. The account given by the boy is vague, and it has varied from time to time. But as far as a connected statement can be obtained from him there seems no reason why a separated epiphysis or a fracture should not have occurred in this as in most other cases. That is to say, no explanation of the dislocation is afforded.

On admission to hospital the left thigh was found to be flexed at the hip-joint to about 45° with the horizontal, and was adducted and rotated inwards. The great trochanter was from an inch to 1½ inches above Nélaton's line. The head of the femur could be felt on the dorsum ilii. The joint was rigid. There was no crepitus along the course of the femur or in the pelvis. Except for an abrasion some 6 inches by half an inch crossing the lumbar spine obliquely, no other injury, external or internal, could be discovered. The case was regarded as a typical dislocation on to the dorsum ilii. But a careful watch for visceral injury was maintained for 12 hours after reduction. Under chloroform anæsthesia induced by Dr. W. T. Simmons, the house physician, the dislocation was reduced without difficulty. Nothing more was necessary in the way of manipulation than weak traction in the line of the misplaced femur, followed by slight increase (about 10 degrees) of flexion. The ease with which reduction occurred was no doubt due to (1) the weak musculature of the young child, (2) the fact that the dislocation was only about three and a quarter hours old, or perhaps also (3) extensive injury to the capsule of the joint.

A radiograph was taken in order to exclude the possibility of further bone injury, such as separation of the epiphysis or injury to the acetabulum. This showed that no such other injury had occurred.

In the after-treatment passive movement was begun on the seventeenth day (rotation, abduction, and adduction), but flexion through more than 5° was delayed until a week later, when active movement was also commenced. The patient was allowed to put weight on the limb on the twenty-eighth day. The result was apparently perfect on the patient's discharge from hospital.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Exhibition of Specimens.—Enlarged Gall-bladder.—Shockless Surgery.

A MEETING of this section was held on March 20th, Dr. R. D. PUREFOY, the President, being in the chair.

Mr. A. BLAYNEY showed a specimen of Cancer of the Gall Bladder from a woman aged 42, who since last Christmas had suffered from distension and pain in the epigastrium and to the right side, with anorexia and occasional vomiting. Examination revealed a tumour in the region of the gall-bladder. On operation it was found that the fundus of the gall-bladder presented a distinct tumour, somewhat nodular on the surface, and involving the liver. The gall-bladder was removed with the object of diminishing the pain. Some gall-stones were found, as is usual in cases of carcinoma. The patient had done well and the pain was relieved.

Mr. S. PRINGLE showed an Ulcer excised from Hour-glass Stomach in a woman who had been sent to hospital with a provisional diagnosis of gastric ulcer. There was a history of symptoms extending over several years. For three weeks preceding admission she complained of very great pain, not regularly after food, but persisting all the time; vomiting was frequent, and for four days before admission almost constant. There was tenderness in the epigastrium to the left of the middle line. On opening the abdomen a very tight hour-glass constriction was found in the middle third of the stomach, immediately above which there was a hard mass adherent to the pancreas. The stomach was divided between two clamps, and on lifting it up the ulcer was detached from the anterior surface of the pancreas. After the ulcer was passed another clamp was put on the stomach, and an end-to-end suture of the two halves of the stomach was done. A drain was put in, which was removed after two days, and the patient made an uninterrupted recovery.—Mr. Blayney thought no operation but the one performed by Mr. Pringle would give a good result.—Mr. W. I. de Courcey Wheeler said that every case of this kind would suggest its own treatment. He had experience of three such cases, and in each of them he decided to do a different operation. One was stricture of the pylorus, and in this case it was easy to anastomose; in the second case it was found easier to do a Finney's operation; and in the third the stomach was resected, and an end-to-end anastomosis was done. In each case the patient did well.—Mr. H. Stokes said he had seen two cases in which a gastro-enterostomy had previously been done to the lower pouch. The patients were not improved, and on reopening the abdomen it was found that the anastomosis had been done to the lower end of the stomach. In both cases another gastro-enterostomy had to be performed.

---

[1] The only other at all similar case that I have been able to find in medical literature is that recorded by the late Mr. Walter Rivington (THE LANCET, 1878, vol. ii., p. 321). But in that case the condition occurred in a considerably older child—a girl aged 13 years. "Under ether it reduced itself." The ease of reduction was thus a comparable experience to that in the present case. I should add, however, that I have not been able to search the literature at all thoroughly.

Mr. R. Atkinson Stoney described a case of Enlarged Gall-bladder with unusual signs. A woman, aged 37, was admitted complaining of a painless lump in the abdomen, which she had noticed for about a year, and which had been increasing in size. On examination there was a lump of about the size of a lemon in the right abdomen, which could be pushed nearly entirely under the ribs and down to the umbilicus; there was very little lateral movement. It seemed immediately under the anterior abdominal wall. Bimanually it slipped up under the ribs with the sensation of a movable kidney, but did not entirely disappear. An incision was made in the loin and a movable kidney found, and a nephropexy was performed. When dressing the case a fortnight later the tumour was again found, if anything larger than before. An abdominal incision was made and a greatly distended gall-bladder found adherent to the inner surface of a well-developed Riedel's lobe. A large round stone was felt impacted in the cystic duct. The gall-bladder was removed and the patient left hospital three weeks later. The gall-bladder was full of opalescent mucoid fluid, and a second stone was found loose, about the same size as the impacted stone, and with a facet on either end, each of which fitted exactly the facet on the other stone. The physical signs were explained by the presence of the two conditions.—Mr. Pringle said this case was another example of the difficulty of diagnosis of these tumours, and pointed out that mistakes were very likely to be made. In such a case he would have performed cholecystectomy, whereby the whole organ could be completely taken away without the risk of infecting the peritoneum.—Mr. Blayney said he had at present under his charge a patient presenting all the signs enumerated in this case—namely, movable kidney and distended gall-bladder. She was aged 30, and had been treated for duodenal ulcer. He made a diagnosis of tumour in the gall-bladder. The anterior surface of the tumour came close to the abdominal wall and to the umbilicus, which was a condition not met with in movable kidney.—Mr. D. Kennedy recalled a specimen, shown by him five years ago, of gall-bladder filled with calculi down as far as the pelvis, and said it was only when an incision was made down on the gall-bladder he found it had reached into the peritoneum. He considered it difficult in some cases to distinguish between tumour of the kidney and tumour of the gall-bladder. In cases where the gall-bladder was removed at operation difficulty was experienced in draining the bile-ducts.—Mr. Stokes mentioned that although these tumours of the gall-bladder might not be malignant, papillomata were usually met with, and it was often very hard to decide whether they were malignant or not.

Mr. Wheeler read a paper illustrated with lantern slides on Crile's Method of Shockless Surgery (Anoci-association).[1] He reviewed his own experiences for the past few months, and while admitting that the theory and practice were not ideal at present, a remarkable advance had been made towards the prevention, either transient or permanent, of ill effects from operations. In many cases after prolonged major operations the patients had little or no sensation of pain, there was no reactionary rise of temperature, no quickening of the pulse, and no manifestation of shock, great or small. It was likely that Crile's discoveries would mark a new era in surgery, and that a development of the principle of anoci-association would be as definite a milestone in surgical progress as the control of hæmorrhage in the days of John Hunter and the triumph of asepsis through the efforts of Lister.

Mr. Wheeler stated that for ten years he had used novocain in conjunction with general anæsthesia, and for the past two years had, in addition, administered omnopon and scopolamine prior to operation. For the last few months he had been converted by the work of Crile and the advocacy of Moynihan to a very systematic infiltration of the tissues and to the employment of urea and quinine.—Mr. Stoney said he had no practical experience of the subject, but while anoci-association was very sound in theory he considered in practice it was slightly different. The operations which he found associated with shock, and where shock was sometimes fatal, were cases of emergency abdominal operation, especially those of strangulation or obstruction, and in such cases he did not see how anoci-association could be carried out, as one of the reasons for the shock was the handling of the intestines, and he suggested that unless one infiltrated the whole of the root of the mesentery a great deal of the shock could not be done away with. This procedure he held to be impracticable in such a case on account of the time necessary to carry it out. In extensive amputations or removals of large tumours one might be able to improve the patient's chances by adopting anoci-association, but for general operative treatment, or where the number of operations to be performed on the same day was large, it was not practicable.—Mr. Wheeler, in replying, said he was aware that one could, of course, get on tolerably well without this procedure, but so much did the patients think about the operation that they often afterwards dated every occurrence from the time of operation. He held that a slight rise of temperature was due to shock. Crile's idea was to have no shock. He agreed as regards the cases of intestinal obstruction. The faster and less complicated the operation in these cases the better would be the result. He agreed that excitement was caused by omnopon if the patient was wakened up. Moreover, it was hard to give ether after omnopon, as the patient breathed very slowly. Urea and quinine did not cause necrosis of the tissues. Local anæsthesia without general anæsthesia was not anoci-association at all. In reply to the President, he was of opinion that strychnine was bad to administer in any case of shock, although he recognised that there was much diversity of opinion in the matter.

SECTION OF MEDICINE.

Carbolic Acid Poisoning.—Incontinence of Urine in Nervous Diseases.

A meeting of this section was held on March 27th, Dr. J. F. O'Carroll, the President, being in the chair.

Dr. Walter G. Smith (the President of the Academy) related the case of a woman, aged 34, seven months pregnant, who accidentally swallowed about a teaspoonful of liquid carbolic acid. She quickly lost consciousness, and was brought to hospital in a comatose state. After some hours, under appropriate treatment, she recovered consciousness, and made a good recovery. The urine, drawn off by catheter about two hours after taking the poison, was dark yellow, and after a while darkened to a cairngorm brown colour. Some of the vomited stuff was distilled off H_2SO_4, and the clear distillate gave evidence of presence of phenol by the following tests, which were shown: (*a*) Fe_2Cl_6; (*b*) precipitate with bromine water; (*c*) red with Millon's reagent; and (*d*) blue with NH_3 and Br (indophenol). Reference was made to the excretion of phenol, which is, mainly, as paired (conjugated) compounds of glycuronic and sulphuric acids, and partly as di-hydric phenols (hydrochinon and pyrocatechin). The colour changes are due to unknown products arising from oxidation of these substances. The slight reducing power sometimes observed in carboluria is due to the glycuronic acid compounds. Glycuronic acid is a carbohydrate derivative. The excretion of phenol as phenyl-sulphates which are relatively innocuous has two consequences—(*a*) utility of freely administering sodium sulphate so as to favour formation of phenyl-sulphate; (*b*) diminished precipitate upon adding $BaCl_2$ to the urine because the SO_4 is locked up in the complex ion, phenyl-sulphuric, whose Ba salt is soluble.—The President complimented Dr. Smith on his interesting paper, and said most of the senior Fellows present had seen black urine during their student days in people who had been plentifully treated with carbolic acid. He had seen it following treatment with pyrogallic ointment.—Dr. R. Travers Smith inquired what would be considered a safe intravenous dose of phenol. He remembered some cases of tetanus that had been treated by the President by intravenous injection of phenol, and he was anxious to know in bad cases where the treatment might require to be pressed to what point it might be safely done.—In connexion with Dr. Travers Smith's remarks, the PRESIDENT said he did not think the dose was given intravenously, and as well as he remembered the strength of the solution was 1 in 200 c.c. given twice daily into the tissues.—Dr. T. P. C. KIRKPATRICK said he would like to know if, as long as the ordinary sulphates were present in the urine, the patient was unlikely to suffer from carbolic acid poisoning. He also inquired as to the utility of alcohol in these cases of carbolic acid poisoning.—Dr. W. BOXWELL also spoke of the utility of alcohol in cases of carbolic acid poisoning, and said he had experience of a number of cases treated in this way at the Meath Hospital.—Dr. G. E. NESBITT corroborated Dr. Travers Smith's testimony as to the utility of phenol in cases of tetanus administered subcutaneously.—Dr. W. G. SMITH, replying, said he was much interested in the subject of carbolic acid being given in large doses, and pointed out that it would be impossible to inject anything in the way of strong carbolic acid into the veins without injury. Referring to Dr. Kirkpatrick's remarks regarding sulphates, he said if the case was a slight one, and it was found that the urine gave no reaction with chloride of barium, it showed that the sulphate was locked up by the carbolic acid. It would do a patient no harm to give an extra dose of sulphate of sodium. He agreed that alcohol was a valuable remedy, and thought that the best thing to do would be to wash out the stomach with alcohol.

---

[1] The Lancet, July 5th, 1913, p. 7.

Dr. BOXWELL read a paper on Incontinence of Urine in Nervous Diseases. He contended that the sharp distinction between the so-called "active" and "passive" incontinence did not exist either in the forms or under the circumstances usually set forth in medical text-books. This he thought particularly evident in the behaviour of the bladder in cases of myelitis at different levels in the cord. He thought that the statement of the *modus operandi* of this organ, and the theory invented to explain it, were both open to question. The existence of any "bladder centre" in the cord was extremely doubtful, and as to the conducting tracts controlling such a centre there was nothing whatever known about them. Dr. Boxwell favoured the view propounded by Müller, that the real centre was in the hypogastric plexus. He thought that micturition was a compound process, involving a true peripheral neural reflex for evacuation of the bladder over which we had no control, and accessory coördinate reflex acts of the abdominal and perineal muscles over which we had control, and which supplemented the act of evacuation, allowing of its consummation in a neat and satisfactory manner. In support of the view that the true centre was in the pelvic plexus Dr. Boxwell adduced (1) the acknowledged existence of the peripheral peristaltic reflex—for which no centre in the cord was claimed; (2) that recent embryological research pointed strongly to a common developmental origin for the bladder, rectum, colon, cæcum, and lower ileum, and it was, therefore, reasonable to suppose that they should all have a similar nervous mechanism; (3) that the existence of very large numbers of nerve cells in the pelvic plexus made the existence of such a peripheral reflex possible. For the anatomical observations in support of this view Dr. Boxwell was indebted to Professor A. F. Dixon.—The paper was discussed by the PRESIDENT, Dr. W. G. SMITH, Dr. PURSER, and Dr. TRAVERS SMITH.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held on April 2nd at the Great Northern Central Hospital, Dr. T. Wilson Parry, the President, being in the chair.—Dr. H. C. G. Semon showed a case of Hydroa in a boy aged 8½ years. The eruption, which was limited to the face, ears, and backs of the hands—namely, those parts of the body exposed to light—had been present for a year and had been equally troublesome both in the summer and winter, thus differing from the type of case described by Hutchinson under the name of summer prurigo. The condition had not been improved by any of the remedies recommended in the literature, but inasmuch as these cases almost invariably recovered of themselves towards puberty the prognosis was good.—Dr. C. M. Hinds Howell showed a youth suffering from Juvenile Tabes, who came under observation for a broken leg in November last. The fracture was quite painless and united firmly. The symptoms presented were fixed pupils, some slight atrophy of the thenar muscles, particularly on the right side. In the lower extremities there was general muscular hypotonia with double pes cavus, marked loss of deep and common sensibility in both legs, with absence of deep reflexes. The Wassermann reaction was positive.—Dr. Harry Campbell showed a woman, aged 26, in whom all the Subcutaneous Fatty Tissue had disappeared above the level of the pelvis. The atrophic process began in the face at the age of 6, and had since steadily spread downwards. Over the affected area the skin was unusually greasy, suggesting that the disappearance of the fat might be due to excessive activity of the sebaceous glands.—Mr. G. B. Mower White showed a man, aged 62, with Double Femoral Hernia, in whom another hernia, a left inguinal, had supervened. Reference was made to 831 cases of femoral hernia collected by Berger, 506 of which were simple (335 on the right side and 171 on the left), 215 bilateral, and the remainder, 110, were associated with other hernias.—Dr. Dan McKenzie showed a patient whose larynx had been removed for epithelioma 15 months previously. The expectation of life in such cases did not naturally amount to much, as the cancer was advanced before such an operation was undertaken. In early cancer of the larynx, on the other hand, the prospects after thyrotomy were as favourable as those of cancer of the lip after removal. —Mr. Cecil Rowntree showed a specimen of Carcinoma of the Rectum, which was remarkable for the presence of a large number of polypoid adenomatous tumours varying in size from that of a pea to a walnut. On microscopic section several of the polypoid tumours showed carcinomatous changes. The rectum had been removed by the late Mr. Cecil Leaf by the combined abdomino-perineal operation; the patient recovered well and returned to work, but ultimately developed recurrence and died two years after operation.—Dr. P. R. Ingram showed a Plated Fracture of the Femur, which broke three months after the plating operation owing to a sudden strain. The patient ultimately made a good recovery with extension treatment; the broken plate was not removed. It was evident that plating sufficiently accurate to produce complete immobility of the broken ends delayed union. It was better in these cases to give extra time and care in the after-treatment.—The President showed a specimen of fistulous opening between the sigmoid flexure and the bladder. The specimen was removed by Mr. Mower White from a man, aged 65, who, after suffering for many years from constipation, had an acute attack 2½ years ago, with pain, tenderness, and a swelling nearly the size of the closed fist in the left iliac region a little to the left of the middle line. The patient refused medical aid, and the illness dragged on for a considerable time. On Nov. 16th last the temperature, which had never been normal, began to run a septic course. The urine gave a marked cloud of albumin, pus cells were plentiful, and there were a few hyaline and granular casts. On cultivation the bacillus coli communis was grown in abundance. A vaccine prepared by Mr. Ernest Shaw was injected once a week from Nov. 19th. The bladder was washed out daily. On Feb. 18th fæces and gas were passed with the urine. This occurred for nearly six weeks, when an operation was performed. Mr. Mower White separated the bladder from the sigmoid flexure, stitched up the opening in the bladder, and removed a large inflammatory mass from the sigmoid, bringing the two ends of the bowel together and uniting them. The patient was making an excellent recovery.—Mr. Ernest H. Shaw showed several specimens of Diverticula of the Sigmoid Flexure and made a few remarks on the pathology of this condition. They occurred in persons usually at middle age and later, usually in obese individuals and most commonly in men. The common situation for these pouches was the sigmoid, but they also occurred in other parts of the large bowel, including the vermiform appendix—rarely found in the rectum and small intestine. In the sigmoid there might be a few or they might be present in large numbers. He showed a sigmoid flexure containing 75 of these pouches.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 3rd, Dr. David Ross, the President, being in the chair.—Dr. Philip Hamill read a paper on the Clinical Aspects and Treatment of Disordered Action of the

Heart, in the course of which he said that some 10–15 per cent. of all adult patients on the medical side complain of symptoms referable or referred by them to the heart. One of the commonest symptoms is palpitation, or a consciousness of the heart beat with associated discomfort. This symptom is most marked in patients in whom there is flatulent distension of the stomach; it is frequently associated with disturbances of the cardiac rhythm. The cardiac discomfort experienced by athletes and those engaged in laborious occupations, who have been attacked by some febrile illness, is characterised by slow return of the pulse-rate to normal after exertion and by the occurrence of premature contractions. Great slowing of the rate of the heart, apart from jaundice, is not infrequently seen. It is natural to some individuals, especially athletes; it also occurs in convalescence from certain fevers and in the condition known as complete heart-block in which the communicating path between auricles and ventricles is divided as the result of disease; the ventricular rate is then usually about 30, whilst the auricular rate is normal. The distinction between slowing of the whole heart and complete heart-block is of clinical importance; for the latter condition indicates a much damaged myocardium. Apart from instrumental methods and those cases in which the auricles can be heard to beat with a different rhythm, the two groups can be distinguished by the effects of excitement and exercise, which in heart-block leave the ventricular rate unaltered. Extreme rapidity of the heart's action is also met with, especially in Graves's disease and paroxysmal tachycardia, though some individuals, apparently normal otherwise, may have a pulse-rate as high as 300 per minute. In auricular fibrillation the pulse-rate is sometimes very high. Irregularity of the heart beat may arise from various causes. 1. The whole heart may beat normally, but with an irregular rhythm. This condition is common in children and has no clinical significance. It is well exemplified in dogs. 2. Certain beats arising at the sinus may cause contraction of the auricle, but the wave may fail to reach the ventricle. This condition of partial heart-block is not uncommon in fevers, especially rheumatic fever, pneumonia, and diphtheria, and indicates serious involvement of the musculature of the heart. It is important that it should be distinguished from the first variety, for it requires complete rest in bed. 3. Abnormal, premature beats may arise at foci other than the normal pacemaker and disturb the rhythm of the heart; they are followed by a compensatory pause. Such premature beats are usually feeble and may not eject sufficient blood to cause a pulse wave palpable at the wrist. Premature beats are often associated with a peculiar sensation of void followed by a thumping in the chest and feeling of sinking. They occur occasionally in almost all normal individuals, particularly in those who smoke to excess. The pulse irregularity which they produce disappears on exertion sufficient to cause the rate to rise to about 120. By themselves they have probably no special significance, but in a heart already damaged by disease they probably indicate the presence of foci of irritation and thus aggravate the severity of the prognosis. They are best treated by reassuring the patient, removing the exciting cause, and by attending to dyspepsia and flatulence; bromides are very useful. 4. Paroxysmal tachycardia consists essentially of a series of premature beats arising in the auricle. The pulse-rate is usually over 140 per minute, and the condition is often readily distinguishable by the constancy of the pulse-rate regardless of posture. Attacks if prolonged may prove fatal from heart failure, but they usually terminate abruptly with great relief. Prolonged attacks may be associated with epigastric tenderness and rigidity, but may be distinguished from acute peritonitis by the constancy of the pulse-rate and enlargement of the liver. Treatment is unsatisfactory; some patients can terminate the paroxysm by pressure on the abdomen or by adopting some particular posture. Drugs are of little avail. Prognosis depends on the frequency and severity of the attacks and the presence of valvular lesions. 5. Auricular fibrillation is responsible for the "pulsus irregularis perpetuus." It is present in a very large proportion of failing hearts, and is usually permanent when once it sets in. The patient does not usually survive its onset by many years. Treatment is most successful in cases with a high pulse-rate. Digitalis is the most useful drug, and should be given in full doses until the desired effect is produced. In urgent cases intravenous injections of strophanthus work wonders. Care must be taken to stop the drug should coupled beats of the ventricle appear. 6. Pulsus alternans or alternate large and small beats usually need a pulse tracing for their recognition. They are of dire prognostic significance, for they indicate an exhausted myocardium.—A specimen of Atheroma of the Coronary Arteries from a patient who died suddenly was shown for Dr. A. F. S. Sladden.—Mr. J. J. Udale showed a Heart weighing 21 oz. from a man, aged 46, having a vertical patch of calcification.

West London Medico-Chirurgical Society.—A clinical meeting of this society was held on April 4th at the West London Hospital, Dr. F. S. Palmer, the President, being in the chair.—The President showed a case of Wasting of the Muscles of the Shoulder-girdle of nine months' standing in a man. Fibrillary tremors excluded a myopathy, and suggestions as to the diagnosis were asked for. Syphilis was denied.—Dr. E. G. Fearnsides suggested the probability that the lesion was due to syphilis, and advised that a Wassermann reaction should be carried out.—Dr. J. M. Bernstein showed cases of Polycythæmia with splenic enlargement in husband, wife, and son; also a case of Myxœdema in a woman whose daughter was attending Dr. G. Pernet for Alopecia Areata. Both cases were controlled with the administration of thyroid extract.—Dr. Bernstein also showed a case of Splenic and Hepatic Enlargement in a sailor. The Wassermann reaction was positive, and Dr. Bernstein intended to show the patient at a subsequent meeting after treatment with salvarsan.—Dr. E. A. Saunders, Dr. D. N. Nabarro, Dr. S. Wyard, and Mr. H. Tyrrell Gray discussed these cases.—Dr. Pernet said that the daughter of the myxœdematous patient under Dr. Bernstein's care improved as regards the alopecia with the administration of thyroid extract, but relapsed when this drug was discontinued.—Dr. L. C. T. Dobson (for Mr. Donald Armour) showed a case of Syphilitic Disease of the Cervical Vertebræ in a man; also a case of Enlarged Liver and Spleen in a boy whose Wassermann reaction was positive. Salvarsan was given a week ago, and, though the splenic and hepatic enlargement had not altered, the temperature was now normal, and the general condition had greatly improved. Dr. Dobson also showed (for Mr. Armour) a case of Complete Excision of the Tongue, with intelligible speech, and a case of Multiple Gummata of the Tongue.—The notes were read of a case of Cruroscrotal Hernia under the care of Mr. W. McAdam Eccles.—Dr. H. J. Davis showed a case of Chronic Œdema of the Eyes and Nose with pus in the antrum.—Dr. Saunders showed a case of Congenital Syphilis with Recurrent Periostitis of both Tibiæ and Ulcerating Gumma of the Palate.—Dr. Pernet showed a case of Double Primary Chancre of the Lips and a typical secondary rash. There was no lesion of the external genitalia. Dr. Pernet also showed a case of Angioma Serpiginosum.—Mr. N. Bishop Harman showed a Horn of the Lower Eyelid; some Types of Hair; a case of Coloboma of the Iris; and a case of Embolism of the Central Artery of the Retina in a man in whom no primary lesion could be discovered.—Dr. T. Grainger Stewart showed a case of Toxic Polyneuritis and a case of Hysterical Paralysis. The cases were discussed by Mr. H. S. Souttar.—Mr. Tyrrell Gray and Dr. Nabarro showed a Sarcoma in a Keloid of the Eyebrow (exhibited at a previous meeting) cured with one application of radium. Dr. Nabarro showed sections of the tumour which proved the growth to be a small round-celled sarcoma.—Mr. Souttar showed the following cases of nerve injury: 1. Paralysis of the Deltoid from direct injury. 2. Injury of the Posterior Interosseous Nerve, with recovery after operation. 3. Injury to the Posterior Cord of the Brachial Plexus, the result of dislocation. 4. Paralysis of the Fifth and Sixth Cervical Nerves in a child, the result of anterior poliomyelitis. 5. Paralysis of the Ulnar Nerve after injury, the paralysis remaining at present being probably functional.

Erratum.—On p. 1039 of The Lancet of last week, on the twelfth line from the foot of the second column, occurs a clerical error in our account of the proceedings of the Medical Society of London. For "Mr. H. W. Carson spoke," read "Dr. J. G. Garson spoke."

Reviews and Notices of Books.

The Fæces of Children and Adults: their Examination and Diagnostic Significance, with Indications for Treatment.

By P. J. CAMMIDGE, M.D. Lond. London: Simpkin, Marshall, Hamilton, Kent, and Co.; Bristol: John Wright and Sons. 1914. Pp. 516. Price 17*s*. 6*d*. net.

THAT much valuable information as to conditions prevalent in the alimentary canal might be obtained from examination of the fæces has long been evident, but though knowledge has so far come wisdom has lingered, in that no very satisfactory methods of study have been available, the bacterial flora in particular being so abundant as to render accurate differentiation of individual organisms a matter of the greatest difficulty. Even now we can claim little more than that a beginning has been made and some progress effected by the work of such observers as Herter, Hecht, Schmidt and Strasburger, and others, towards laying the foundations of a scientific study of this field.

Dr. Cammidge's book will be welcomed both as the production of one who is himself an authority on the subject and as giving a convenient epitome of the existing state of knowledge. The introduction deals with the method of collecting fæces for examination and with their general characters. The next two chapters are devoted to naked-eye and microscopical examination of normal and pathological stools, while the fourth treats of animal parasites and pseudo-parasites, a useful plate being given showing the commoner objects which may counterfeit parasites, such as cotton threads and débris from various vegetables. Chapter V. deals with bacteriological examination and with the classification of the organisms present in the fæces, more information being apparently obtainable from a general study of the type of bacteria present in any case than from a detailed investigation of the individual species. The Gram method of staining, for example, affords a useful means of dividing the mass of germs into two categories and of obtaining a general idea of the most prevalent varieties. The fæces of breast-fed and bottle-fed babies show a sharp differentiation by this method. Some good coloured plates are employed to illustrate this section. Chapters VI. and VII. contain an account of the chemical analysis of the fæces, in the moist and in the dry condition respectively, and Chapter VIII. treats of the various calculi which may be passed. It is interesting to note that if a very digestible diet is given the fæces passed consist almost entirely of bacteria and matters derived from the intestinal walls. From a medical point of view, perhaps, the two concluding chapters are the most interesting, as they deal with the diagnostic value of examination of the fæces and with the indications for treatment derived from them. It would seem that a complete alteration of diet may be followed by almost as complete a change in the flora of the intestine, and that useful therapeutic measures may in time be devised and controlled on such a basis.

Schemes of dietary are given in an appendix to this book, which is also furnished with a full index and with bibliographies to the separate chapters. There are many illustrations throughout besides those which we have already mentioned, and the print and paper are excellent. We commend the book to all who are interested in the scientific side of our profession as a stimulating contribution to a comparatively little-known province of physiology and medicine.

La Lèpre à Travers les Siècles et les Contrées.

Par le Dr. DEMETRIUS AL. ZAMBACO PACHA (de Byzance). Paris: Masson et Cie. 1914 Pp. 864. Price 12 francs.

LEPROSY, according to modern research, is a disease which goes back to prehistoric times and one which has everywhere excited fear, repulsion, and, to the credit of Christianity be it said, sympathy. Dr. Zambaco Pacha, who devoted most of his life to the study of leprosy and who died just as the work now before us was being prepared for press, has produced a most interesting book even if it be one which, like many a work written by an enthusiast, contains statements for which there is insufficient evidence. Had he lived to see a second edition there is little doubt but that he would have modified some of these.

His thesis is that leprosy originated somewhere in Central Asia, probably Northern India. Thence it spread to Egypt, where the Jews contracted it; but the main agents of its transmission throughout the world were the Phœnicians, who were without doubt daring and intrepid navigators. So far we can agree with Dr. Zambaco, especially as Hippocrates calls the "leuke," or white leprosy, the "Phœnician disease." But when in his eagerness to prove his thesis he argues that the Argonauts were all infected with leprosy which they and their ancestors had received from the Phœnicians we are fain to call a halt, for the statement is made without the slightest evidence to support it, unless, indeed, we allow that because leprosy was known to exist in ancient times throughout the countries traditionally visited by the Argonauts, therefore the Argonauts had carried the infection. Dr. Zambaco quotes the account of the visit of the Argonauts to Lemnos, and their dealings with the Lemnian women. These women, he says, may easily have been infected by their lovers, and he then calls to mind the tradition that the Lemnian women were attacked with a form of ozæna. The tradition undoubtedly exists, but the ozæna was inflicted as a punishment by Aphrodite long before the arrival of the Argonauts.

To pass to historical times. Dr. Zambaco, to make a rhetorical point, says (p. 77), "Le christianisme et la lèpre firent ensemble leur entrée solennelle à Byzance." Then he quotes as a legend "borrowed in a small degree from history" the story of Constantine being a leper, a story which has long been exploded, while on p. 79 he allows that leprosy existed in the country before the installation of Constantine at Byzantium. The disease continued to be a scourge throughout the Eastern Empire, and in 372 A.D. the great St. Basil erected a lazar house, or rather town, outside the walls of Caesarea, a description of which has come down to us in the pages of Sozomen, and in the funeral oration on Basil delivered by St. Gregory Nazianzenus, who refers to the institution as follows: "Why should I compare with this work Thebes of the seven portals [then he mentions the remaining seven wonders] or the size and beauty of shrines which are no more. ...... There is no longer before our eyes that terrible and piteous spectacle of men who are living corpses, the greater part of whose limbs have mortified, driven away from their cities and homes and public places and fountain, aye, and from their dearest ones, recognisable by their names rather than by their features ..... no longer the objects of hatred instead of pity, on account of their disease; composers of piteous songs, if any of them have their voice still left to them."[1] From this vivid picture we can form an idea of the lot of the leper before charity came to his aid, and even after an asylum was provided for him in some places many a leper had to "dwell without the camp," though the Church provided a form of putting away in which kindliness took the place of hatred. Dr. Zambaco (p. 123) gives the form in use in France, in the diocese of Troyes, about 1425. Those who care to study the Sarum Use will find it given in Appendix A of Miss Rotha Mary Clay's "Mediæval Hospitals of England."

Dr. Zambaco calls his book an anthology, and it is, in fact, rather a series of papers on various aspects of leprosy than a continuous work, such papers being arranged in a somewhat confused manner. Some of his theories, though plausible, will not meet with general acceptance; such, for instance, is his statement that Morvan's disease, syringomyelia, morphœa, and sclerodactyly are all forms of aborted or attenuated leprosy. He considers that leprosy is a bacillary disease, and that the specific bacillus is that discovered by Hansen, but he is also of opinion (p. 747) that leprosy with all the classical clinical symptoms can exist without the bacillus being discoverable, and he gives as a reference (p. 156) in support of this theory an admission by Hansen in Virchow's *Archives* for 1902. Much of the work is taken up with a survey of leprosy as it exists at present in nearly every country of the world, and these sections contain a mass of statements and statistics. Other sections deal with the bacteriology, the contagiousness, and the curability of leprosy. Dr. Zambaco does not hold with the contagiousness, and does consider the disease curable. There is no need to be afraid of leprosy, but lepers are best treated in agricultural colonies, where they can live under good hygienic conditions, and where wholesome work prevents them dwelling upon their unhappy condition.

In the concluding section of the book Dr. Zambaco reverts to his favourite Phœnicians, and in an illuminating essay upon the megalithic monuments of Brittany adduces an elaborate argument to show that the Phœnicians colonised what is now Brittany at a very early date; that they built the megalithic monuments the inscriptions on which are derived from various symbols which they had met with in African and Asiatic lands; and finally, that they introduced leprosy, the morbus Phœnicicus, into ancient Armorica, as they did into all the other lands they visited, where it exists more or less widely to-day.

Although Dr. Zambaco's views may be considered visionary here and there, yet none the less his work is of great interest and is evidently the result of the labours of a lifetime.

Localisations Cérébelleuses.

Par ANDRÉ-THOMAS et A. DURUPT. Paris: Vigot Frères. Pp. 197. Price 6 francs.

IN 1897 Dr. André-Thomas published an important memoir on the cerebellum. Along with A. Durupt during the last two years more work has been done in the laboratory of Professor Dejerine on cerebellar localisation, and the result is before us. The first part deals shortly with the history of cerebellar research, the comparative anatomy and physiology of the organs, including Bolk's nomenclature, as well as with the actual state of our knowledge on cerebellar localisation. In the second part the authors give an account of their own researches on the dog and monkey. Injuries of various portions of the cortex were made and the effects, immediate and remote, observed and studied. In all, the results on 11 dogs and four monkeys are given.

A special chapter is devoted to observations made on monkeys immobilised in various ways with a view to studying the action of various groups of muscles, according to the animal's position. In the third part the authors review these experiments and proceed to interpret their results. They conclude that there are centres in the cerebellar cortex which affect limited regions of the body. In the cerebellar cortex are represented the musculature of different parts of the body. The vermis contains the centres for the muscles of the head, neck, and trunk. Each hemisphere contains centres for the limbs of the same side, and there is a centre associated with the upper limb, and another and distinct centre for the movements of the lower limb. Each centre is made up of secondary centres in relation to the movements at each joint by means of a special coördination of muscles, e.g., extension, flexion, abduction, and so on—that is, they are *centres of direction*. A considerable number of photographs, both of dogs and monkeys, elucidate the text.

This brochure is a welcome contribution to our knowledge of the organ which lies astride the junction of the cord with the brain. The facts observed stand well in harmony with clinical observation as well as with the facts of pathology. Physiologists and clinicians alike will be glad to have this succinct *résumé* of the facts relating to cerebellar localisation.

Syphilis and the Nervous System.

By Dr. MAX NONNE, Chief of the Nervous Department of the General Hospital, Hamburg-Eppendorf. Authorised translation from the second revised and enlarged German edition by CHARLES R. BALL, B.A., M.D., Chief of the Nervous and Mental Department, St. Paul Free Dispensary, St. Paul, Minnesota. With 98 illustrations in the text. London and Philadelphia: J. B. Lippincott Company. 1913. Pp. 406. Price 18*s*. net.

Dr. Nonne's book on syphilis and the nervous system is already familiar to many neurologists, both in this country and in America. Its high merits have won it a permanent place in neurological literature. The present edition, in English, has on the one hand been rendered somewhat shorter than the German edition by the omission of a number of case histories; on the other, it is an improvement on the last German edition, inasmuch as Dr. Nonne has taken the opportunity herein provided of rewriting the original chapters on the so-called "four reactions," and he has added a chapter on salvarsan therapy. In this way the English edition has been brought up to date, an important matter when the rapid strides at present being made in syphilology are taken into account.

The volume under consideration supplies elaborate and detailed descriptions of both the clinical and the pathological sides of syphilis of the nervous system. Interstitial syphilis, in the form of syphilitic endarteritis, meningo-myelitis, meningitis, and cerebro-spinal syphilis, and parenchymatous syphilis—viz., tabes dorsalis and general paralysis—are fully discussed. There are chapters on syphilis of the peripheral nerves, hereditary syphilis, neuroses and psychoses in syphilitics, and syphilis of the base of the brain; indeed, there appears to be no section of the subject of which the author has not taken cognisance. The book has entailed a vast amount of clinical and pathological research, but it is well put together, and the important principles of the invasion of the nervous system by syphilis are not lost sight of in a multiplicity of detail.

---

[1] Library of Nicene and post-Nicene Fathers, vol. vii.

Several statements of the original author are open to criticism. In view of the work of Marie, Léri, and others of the French school it is misleading to say that "there is nothing in the literature concerning syphilis as a causative factor of amyotrophic lateral sclerosis." Recent advances have made the statement obsolete that "general paresis is not a specific syphilitic disease of the brain." It is said that "with a loss of the light reaction on one side and an optic neuritis on the same side, one may safely diagnose the case as brain lues," but it would be unwise, in our opinion, to go so far as this.

The translation has been on the whole well done. The word spirochæte, however, is not always treated consistently. Thus "spirochæte" is apparently used as a plural. We note "autopsy" used as a verb and "residual" as a substantive. There is a reference to "retinitis albuminuria." There is also a curious and frequent tendency to insert the article "the" inaccurately, as in the following: "Uhthoff from his material found the homonymous hemianopsia 11 times." The reader finds himself pulled up by such sentences as "the changes resemble those found in the posterior column degenerations in humans." It is regrettable that references to the figures are frequently omitted in the text. There is no explanation of Figs. 56–59, which, by the way, are the same as Fig. 53. Figs. 84–90 are identical with Figs. 51 and 52, but the latter are not explained. There are many evidences of careless reading of the proofs, for instance, "thickening of the neurologia" occurs.

These and other criticisms that might be advanced are mentioned solely because the neurologist gladly admits the excellent qualities of the book now offered to a wider public, and it is a pity it should be disfigured by these minor blemishes, which we trust will disappear in subsequent editions.

Manual of Surgery.

By ALEXIS THOMSON, Professor of Surgery, University of Edinburgh; Surgeon, Edinburgh Royal Infirmary; and ALEXANDER MILES, Surgeon, Edinburgh Royal Infirmary. Vol. III., Operative Surgery. Second edition. With 255 illustrations. London, Edinburgh, and Glasgow: Henry Frowde and Hodder and Stoughton. 1913. Pp. 620. Price 10s. 6d. net.

THE third volume of this valuable manual of surgery deals only with the operations, and it contains all that is usually included in such works. We agree with the authors, that in spite of the fact that nowadays arteries are seldom ligated in their continuity, the tying of arteries provides an excellent means for the student to acquire practice in operative manipulations, and furnishes a ready means of testing his dexterity and his anatomical knowledge, and therefore we are glad to see that the authors have retained this section. The whole book has been written by surgeons who appreciate fully the needs of students and the real requirements of operative surgery. The volume is very fully illustrated and we cannot imagine a more useful treatise for the student. It is inevitable that in a work of this kind there should be much that might be discussed, but such discussions would be really out of place in a review of a work intended for students.

The Respiratory Function of the Blood.

By JOSEPH BARCROFT, M.A., B.Sc., F.R.S., Fellow of King's College, Cambridge. Cambridge: At the University Press. 1914. Pp. 320. Price 18s. net.

THE author tells us that "the purely personal point of view from which this volume has been written demands the treatment of the subjects in a personal way." It includes the story of the author's physiological "ventures," and any merits which attach to the narrative—and the merits are many and varied—lie in the fact that it is in some sense first-hand. That which the author has not actually touched he has refrained from discussing, so that such subjects as the relation of narcosis to oxygen-want and the properties of intracellular oxidative enzymes find no place in this volume. The author's desire was to call the book "what it frankly is—a log" (of course, in the nautical sense), but in the end "a less exact though more comprehensive title" was chosen.

The text is divided into three parts. Part I. deals with the chemistry of hæmoglobin (pp. 1–72); Part II., the passage of oxygen to and from the blood (pp. 73–217); Part III., the dissociation curve considered as an "indicator" of the "reaction" of the blood (pp. 218–289). The remainder of the text is taken up with appendices chiefly devoted to an account of methods.

The "specific oxygen capacity" of blood or hæmoglobin—i.e., the number of c.c. of loosely combined oxygen corresponding to each gramme of iron in the compound—is first dealt with. Hæmoglobin may differ in different species, but it is a unique compound, and the author suggests that "but for its existence man might never have attained any activity which the lobster does not possess, or had he done so, it would have been with a body as minute as the fly's." Blood carries about 40 times as much oxygen as the same volume of plasma. This we may remember, but anyone wishing to follow intelligently the author's narrative should make himself acquainted with the modern methods of gas analysis of the fluid of the body, where everything depends upon working with the minimum quantity of gas. A few drops of blood suffice, so accurate is the present technique. Next follows a discussion on the dissociative curve of hæmoglobin, the effects of temperature and electrolytes on the affinity of hæmoglobin for oxygen, and the effect of acid on the dissociation curve of blood. The effect of increased acidity is to lessen the effective concentration of the oxygen in the solution which contains the hæmoglobin.

Part II. begins "with the call for oxygen by the tissues"—i.e., what is called "internal respiration." It is the cell that primarily determines not only its own nutrition but also its respiratory wants. The author elaborates the theme that there is no instance in which it can be proved that an organ increases its activity under physiological conditions without also increasing its demand for oxygen. This theme is elucidated by the results of gaseous exchanges in skeletal muscle, in which, as in other organs, the increased oxygen consumption survives the increased functional activity. Similar results are obtained with the heart and its gaseous exchanges. The results obtained with adrenalin, pilocarpine, atropine, and chloroform are both striking and convincing. The author professes himself an enthusiast for the beautiful work of Rohde on this subject. After contractile organs, the best attested case of functional activity going hand-in-hand with oxygen consumption is the kidney. Then follows a review of similar work on the salivary gland, pancreas, and liver. However these organs are excited it is shown that in no organ excited by any form of stimulus is it found that positive work is done without the blood supply having to respond to a call for oxygen. The call for oxygen is then considered as a physiological test, and in this relation diuresis and the kidney are considered. As to the metabolism of the blood itself, an interesting observation of Morawitz is made much use of —viz., that the blood of anæmic animals has a very considerable metabolism, which is due to the fact that in such animals young unnucleated red corpuscles are present in large numbers. This matter is discussed in relation to an increased formation of red corpuscles at high altitudes.

A very interesting chapter is that on the regulation of the supply of oxygen to the tissues. It is remarkable to note that the oxygen used by the liver is unaffected if the portal vein be ligatured altogether and its blood diverted into the general circulation without passing through the liver. Are there local chemical products the result of metabolism—e.g., CO_2, lactic acid, which have the power of distending blood tissues? The answer is yes. The evidence is very carefully and judicially considered as regards the submaxillary gland, pancreas, and heart. Next the author deals with the unloading of oxygen from the blood, and the rate of exchange between the blood and the tissues. The two chapters on the acquisition of oxygen by the blood in the lungs are amongst the most interesting in the book. In them the author gives a masterly analysis of the diffusion and secretory theories as they apply to the gaseous exchanges in the lungs. The effect of diet and of high altitudes on the dissociation curve of blood, exercise, acidosis, and some cognate matters are then discussed.

Every physiologist will welcome most warmly this most interesting and largely personal narrative of a masterly series of observations. Many secrets still lie hidden in this mysterious and as yet but partially explored "internal medium," to use the apt phrase of Claud Bernard.

Genito-urinary Diagnosis and Therapy for Urologists and General Practitioners.

By Dr. ERNST PORTNER, Specialist for Urology, Berlin. Germany. Translated and edited by BRANSFORD LEWIS. M D., B.Sc., Professor of Genito-urinary Surgery, Medical Department of St. Louis University, St. Louis. With 43 illustrations. London: Henry Kimpton; Glasgow: Alexander Stenhouse. 1913. Pp. 221. Price 10*s.* 6*d.* net.

THERE are many affections of the genito-urinary system met with in general practice the treatment of which is fully within the range of the modern general practitioner, but the subject requires more attention than is usually paid to it by the student. This small book has been written exactly with the aim of providing those in general practice with the help they need; it lays stress on the practical points of this department of surgery, and indicates the way of carrying out the necessary procedures. It does not go too deeply into matters which are outside the practical sphere of the general practitioner, who has not wards, laboratories, and operating theatres at his back, but the author is very complete within the limits which he has set himself. We are pleased to see that a special chapter has been provided containing an account of the affections of the female urethra; this is too often omitted in works on genito-urinary surgery. The translation is good. An appendix has been added on the serological diagnosis and specific treatment of gonococcal infections, which is interesting, but a little beyond the scope of the rest of the work.

LIBRARY TABLE.

Flying. By GUSTAV HAMEL and CHARLES C. TURNER. London: Longmans, Green, and Co. 1914. Pp. 341. Illustrated. Price 12*s.* 6*d.* net.—It is not necessary to be an aviator to recognise in M. Hamel's flying those characteristics, so difficult to describe, which are summed up in the phrase "a good style." There are an appearance of ease, an elegance, a happy sense of mastery about his management of an aeroplane, which are obvious to all beholders. Whether he or Mr. Turner is mainly responsible for the literary form of this joint work it is not essential to inquire very closely, but certainly there is a simplicity and directness about it such as few amateur writers can impart to their books. The style is not so arresting as that of M. Hamel's flying, but at least it is quite fairly good. The treatment is thoroughly practical throughout, and technicalities are either avoided or rendered intelligible to terrestrials. No attempt, in fact, is here made to write an advanced text-book for fliers; but a very readable and informing account, illustrated by a series of splendid photographs, is provided for those whose interest in the subject is mainly that of admiring spectators. The medical aspect of aviation is dealt with in a separate chapter by Mr. J. E. Adler, and here the essentially practical tone of the other chapters is very little in evidence. The greater part of the chapter consists of a *résumé* of the physiological (or pathological) effects of high altitude upon the human organism, expressed in scientific terms calculated to make the information quite unintelligible to the laity.

Handbook of Photomicrography. By H. LLOYD HIND, B.Sc., F.I.C., and W. BROUGH RANDLES, B.Sc. With 44 plates, 85 half-tone reproductions of photomicrographs, and 71 text illustrations. London: G. Routledge and Sons, Limited. 1913. Pp. xii., 292. Price 7*s.* 6*d.* net.—The authors in their prefatory note point out that this book is the outcome of a series of articles originally published in the *Photographic Monthly*, and intended as an introduction to photomicrography from a photographer's point of view. It is, in fact, a technical handbook which deals with all that is of practical value to those desirous of acquiring skill in photomicrography. The elements of the work are fully dealt with under the headings of photomicrographic apparatus, the microscope, lamp, and illuminants. There is a chapter on the experiments of illumination, as regards both critical light and dark ground illumination, and another on the photographic methods applicable to low power work and high magnifications. There are special chapters on colour photography and the reproduction of opaque objects which are of special interest to the metallurgist, and a final chapter deals with the applications of photomicrography in medical practice and the various arts. Throughout there are numerous illustrations showing to what a stage of perfection photomicrography has reached. The medical reader will be especially interested in the beautiful plates of bacteria and protozoa as well as in the coloured reproductions of chromogenic bacteria. Here we note that the authors fall into a common error and talk about flagellæ. The illustrations include some fine kinematograph films of live organisms taken by Messrs. Pathé Frères. There is a useful appendix on histological methods and formulæ for staining and for the various photographic processes. We have merely outlined the scope of this work, but we can highly recommend it as a useful handbook of the technique of photomicrography.

Astrology in Medicine. The FitzPatrick lectures delivered before the Royal College of Physicians of London on Nov. 6th and 11th, 1913. With Addendum on Saints and Signs. By CHARLES ARTHUR MERCIER, Fellow of the College. London: Macmillan and Co., Limited. 1914. Pp. 100. Price 2*s.* net.—Dr. Mercier's lectures have already appeared in abstract in our columns, but their publication in book form will render them accessible to those members of the general public who are not likely to read a professional journal. He treats his subject in a somewhat Labouchерian vein, and we think that he might have made rather more of the historical and medical side of it. His words of warning on p. 75 are very sound, but the "Addendum," which we are glad to see was not delivered as a FitzPatrick lecture, is surely unworthy of the writer.

Lunacy Practice. By WILLIAM H. GATTIE, of Gray's Inn, Barrister-at-Law. Second edition. London: Shaw and Sons. 1914. Pp. 60. Price 2*s.* 6*d.* net.—Mr. Gattie issues the second edition of his "Practical Guide for the Certification and Detention of Persons of Unsound Mind" in a similar form to the first—that is to say, it consists of short notes or abstracts giving the essential parts of the Lunacy Acts so far as they govern certification and detention, accompanied by all necessary forms. The forms have the advantage of being filled up with imaginary names and details concerning imaginary patients, which renders them easier to follow than those which are given in blank. A chapter has been added dealing with summary reception orders. The print is large and easy to read, but smaller type and a smaller page might be found more convenient to handle, or, on occasions, to put in the pocket. Perhaps Mr. Gattie will consider the point in any subsequent issue.

Jahrbuch für Orthopaedische Chirurgie. By Dr. PAUL GLAESSNER. Berlin: Julius Springer. Pp. 110. Price 6 marks.—A most useful little work of reference on recent orthopædics, giving full references to the literature in England, Germany, France, America, and other countries for 1912, with a brief abstract of the various works.

MISCELLANEOUS VOLUMES.

A BOOK that in its German form has attracted much attention is *Spiritual Director and Physician*, by Father V. RAYMOND, O.P., Chaplain to the Kneipp Institute at Woerishofen, an English translation of which (London: R. and T. Washbourne, Limited. 1914. Pp. 334. Price 5*s.* net), by Dom ALOYSIUS SMITH, C.R.L., has recently been published. The original book received the warmest endorsements from Dr. Masquin, Dr. Bonnaymé, and Professor Dubois, of Berne. The book is divided into three parts. In Part I., after a general introduction on suffering, the subjects of neurosis, hysteria, and psychasthenia are dealt with. In Part II. scruples and the confession of the scrupulous, temptation and sin, temptations and purity, and difficulties in prayer are considered. The third part is largely theological, save for the chapter on the treatment of neurosis. So far as the subject matter is concerned, despite the fundamental difference of point of view, Professor Dubois, in his prefatory words, speaking as "a freethinker brought up in Protestantism," is yet able to say: "I shall make a point of placing your book in the hands of those of my patients who suffer from religious scruples, however little religious faith they may have, and you will be an aid to me in my work." The tact of the author is exemplified in the preface, in his answer to the criticism that the question of personal responsibility has been omitted, and thereby the scientific value of the book diminished. To this Father Raymond replies: "This matter was designedly left aside. It is a problem that is calculated to embarrass the best equipped and most balanced minds, whereas these pages must be of such a nature that they can be safely placed in the hands of persons who are nervous and scrupulous, and whose imaginations are beyond all control. Being victims of fear, they are liable to see and retain whatever is likely to trouble them. Place before them any theory regarding responsibility and they would only be impressed by the thought of the obligations and their serious consequences. The cases which exempt from responsibility would escape their notice altogether." The book is worthy of study by clergymen of all denominations and by medical men.——Prayer as a therapeutic agent has been much in the forefront of late. While, as Sir Dyce Duckworth expressed it at the Church Congress in 1910, the medical profession can neither act as thaumaturgists nor sanction any such efforts in substitution for scientific treatment, it will gladly welcome any inspiration and assurance that may come from appropriate ministration at the hands of any Christian minister as a reinforcement of its professional efforts. In reviewing previous books on this subject we have disclaimed any idea of minimising the power of prayer or the consolations of religion to those to whom they appeal. A little book, entitled *Prayers for Healing from the Ancient Liturgies and Other Offices of the Church* (London: H. R. Allenson, Limited. Pp. 96. Price 1*s.* net), compiled by E. B. H., has a suggestive value in this respect, in that it discloses two very important differences in character and tone between the prayers of the early Church in respect of sickness and those of later date. These ancient prayers in no case adopt the depressing assumption that sickness is a divine chastisement, a suggestion which of itself is an anti-therapeutic agent, but, on the contrary, speak always in stimulating and tonic terms of faith and confidence, without any trace of such a limiting clause as "if it be Thy will," the early Church, as the author says, appearing to have entertained no doubt about God's will in the matter of sickness. Herein, we venture to submit, is a possible ground for the greater reputed effect of prayer against sickness in the early Church. No less than 21 different liturgies—i.e., Eucharistic offices—dating from those of St. Mark and St. James in the second century to the 1662 revision of the Book of Common Prayer, are drawn upon.——In view of the exceptionally temperate and obviously sincere and earnest character of *A Plea for the Thorough and Unbiassed Investigation of Christian Science* (London: J. M. Dent and Sons, Limited. 1913. Pp. 204. Price 1*s.* net), by AN ENQUIRER, we mention the receipt of this book here. We have read it carefully from cover to cover and we are unable to see that it advances a single new point or one that has not already been amply considered and, in our opinion, confuted. But in any case we cannot open our columns to a discussion that must be profitless, since argument between people who cannot agree upon the fundamental axioms is futile.

A little book that deserves particular mention at this season of the year, when people are planning what to do during their annual vacation, is *Cheap Continental Holidays* (London: The Scientific Press, Limited. Pp. 172. Price 1*s.* net), by GRACE VALLOIS, who is described as the *Nursing Mirror* Travel Correspondent. In THE LANCET of Jan. 17th last we noticed a good little book, "First Steps in Collecting," by the same lady, and now after reading "Cheap Continental Holidays" we begin to realise how she managed to pick up such extensive practical knowledge of the way to do things. Madame Vallois first shows how it is that some foreign holidays may be made cheaper than those in England. She next makes clear to "all fellow travellers with slender purses" how far £5 can be made to go. Some useful hints to travellers and some admirable remarks on clothing follow. The following trips are described: *The Ardennes, *The Bay of St. Malo, Mont St. Michel, Amsterdam, Lucerne, *Bruges, Caen and Bayeux, the Rhine, Florence, *Ghent, Western Flanders, Caudebec-en-Caux, The Hague, and *Brussels, those marked with an asterisk being places where a short holiday, including travelling, may be spent for £5. These articles are no dryasdust rehash of other guide-books, but are full of the author's personal hints and experiences, with much of history and literary sidelights not to be found in the school-books and guides.

We have received two excellent books on matters relating to household economy. *The Kitchen Garden and the Cook* (London: Smith, Elder, and Co. 1913. Pp. 283. Price 5*s.* net), by CECILIA MARIA PEARSE, is an exhaustive and detailed description of the methods of growing kitchen vegetables and of more excellent ways of cooking them when grown than can be found in any book we have seen. The profusion of methods of cooking is almost bewildering. There is also an excellent chapter on cakes and puddings without eggs, with some hints on cooking in paper bags.——The other book is *Foods and Household Management: a Text-Book of the Household Arts* (New York: The Macmillan Company. 1914. Pp. 402. Price 5*s.* net), by HELEN KINNE and ANNA M. COOLEY, B.S. It is a scientific and clearly and comprehensively written book on food and food values. It contains some 160 carefully selected and tested recipes, with clear directions for cooking not only the things customary among all Anglo-Saxon peoples, but also many American specialties. Reasons are given for all ways of preparing food. The book is full also of practical hints upon housekeeping—accounts, electricity and gas, kitchen apparatus, cleaning fabrics and furniture, how to buy, housewifery, "laundering" and dry cleaning, and so forth. For English readers, however, the section on the household budget will be of little use, being based on an American standard of prices. Moreover, the methods of cutting up a beast differ not a little in America and England. But the English housewife can learn a lot from the book.

JOURNALS AND MAGAZINES.

Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. VII., No. 27. April, 1914. Oxford: At the Clarendon Press. London, Edinburgh, New York, Toronto, and Melbourne: Humphrey Milford. Subscription price, 25*s.* per annum; single numbers, 8*s.* 6*d.* each.—The contents of this number are: 1. Observations on Paroxysmal Tachycardia, by H. G. Butterfield and G. H. Hunt. The term is restricted to cases of rapid and regular tachycardia, where the impulse causing contraction arises at some focus other than the sino-auricular node. In two of the cases described in this article the ectopic focus lay in the auricle, in one in the ventricle, and in the fourth either in the auricle or junctional tissues. The special interest of the paper is due to the fact that in three of the cases post-mortem examinations were made, and the histological investigation corroborated the diagnosis made from the electrocardiograms. 2. Cholesterin: An Account of the Relations to Pathology and Physiology, by J. W. McNee. An interesting review of the literature of this subject is given, together with an account of some experiments. The methods of determining the cholesterin content of the blood serum are briefly discussed. A marked increase in the cholesterin in the serum is found almost constantly in cases of arteriosclerosis, in chronic Bright's disease, jaundice, diabetes mellitus, xanthoma, and pregnancy, while it is decreased in almost all febrile diseases except enteric fever, in tuberculosis, and in old age. It has been found that in jaundice a marked change occurs in the proportions of cholesterin and cholesterin ester. Normally cholesterin ester forms much the larger part, while in jaundice a great increase in free cholesterin is found. The changes in cholesterin metabolism during pregnancy are discussed in relation to the special liability of women to gall-stones. The hypercholesterinæmia during pregnancy is a considerable one, and Dr. McNee has found that there is also a marked increase in the cholesterin of the bile during pregnancy. 3. Bilateral Salivary Swellings (Mikulicz's Disease): A Clinical Review, by Hugh Thursfield. A fatal case of this condition is recorded, and a case in the literature recorded by von Brunn is referred to. Both of them are regarded by Dr. Thursfield as atypical (aleukæmic) leukæmia. Dr. Thursfield refers to eight groups of cases in which bilateral swellings of the salivary glands form the most characteristic symptom. He gives a review of the literature and discusses the pathology of the more important groups. 4. On the Prognosis of Acute Articular Rheumatism, by Charles G. Kemp. A series of cases is analysed to determine what proportion pass through the illness to complete convalescence without showing clinical signs of cardiac involvement, and further, what proportion having shown such signs during the acute stage of the disease progress to complete cardiac recovery. 5. Critical Review: Anaphylaxis and its Bearing on Medicine, by James McIntosh. An interesting and suggestive summary of the phenomena of anaphylaxis and their applications is given, together with the theoretical explanations which have been propounded. 6. Critical Review: Bacterial Endocarditis, by Irving Simons. This is an important and instructive analysis of cases of endocarditis associated with the presence of bacteria in the circulating blood during valvular lesions and in the life.

The Modern Hospital.—This is a monthly journal devoted to the building, equipment, and administration of hospitals, sanatoriums, and allied institutions, and to their medical, surgical, and nursing services. It is published at St. Louis, Mo., and, like most American periodicals, is well printed and illustrated, and contains American views, and descriptions of American procedures, that may be valuable to British workers. The first number opens with an article on the Dividing Line between General Hospital and Hospital for Insane, by Dr. W. A. White, superintendent of the Government Hospital for the Insane, Washington. The author makes a strong plea for the recognition of the fact that insanity is a disease "in a practical manner by admitting people for advice and treatment to the various institutions conducted by medical charity on the same basis as patients are admitted for other maladies." He deplores the fact that the mental patient has, in all countries to some extent, to undergo the tedious and humiliating process of the law which brands him with legal disability before he can obtain relief. He says: "The city that fails in its general hospital scheme to provide for a psychopathic ward loses a golden opportunity."—Dr. W. P. Gerhard, consulting sanitary expert, New York, contributes the first part of a serial on Recent Examples of Hospital Construction in Europe, the result of inspection in a number of German cities of the latest examples of hospital planning, equipment, and construction. In this number he describes the Hospital and Sanatorium at Beelitz, near Berlin. The article is profusely illustrated by plans and views. Some, such as "lavatory with special bowls for mouth gargling," are most instructive.—Miss E. M. Lawler, superintendent of nurses and principal of the training school, publishes a fourth paper on the Organisation of the Nursing Department of Johns Hopkins Hospital. Taking for her motto, "All hinges on attention to details," she minutely describes the system of this famous hospital.—Dr. J. W. Fowler writes about the newly erected Municipal Hospital at Louisville, of which he is superintendent. One of the architectural difficulties was the duplication of the wards, dining-rooms, &c., in order to separate the coloured from the white patients.—Dr. J. F. Clarke discusses the Advantages and Disadvantages of a Small Home Hospital. The new "Iowa idea," by which the people of rural communities are building hospitals for themselves, is spreading rapidly over the United States and is arousing much comment. The medical profession in the cities frowns upon such institutions, but Dr. Clarke believes that they will be universally adopted. He concludes that the balance is in favour of the small hospital near the patient's home. In addition to convenience of access it provides better air, greater quietness, and purer and fresher food, and trains the local practitioners. The individuality of the patient is more recognised and he does not become a "number" as in a large institution. For maternity cases a small hospital is, Dr. Clarke thinks, vastly superior to the patient's home.

British Dental Journal.—In the issue for March 16th Mr. Octavius R. Ennion gives an account of an interesting case of Necrosis of the Mandible. The patient, a girl 11 years of age, had suffered from scarlet fever, the convalescence from which was considerably delayed by a septic condition of the throat. The necrosis of the mandible apparently started from infection through a carious right second premolar. The periosteum was from time to time stripped of the necrosed bone and the buccal cavity drained through an opening behind the angle of the jaw. The entire mandible, with the exception of a small portion of the left ascending ramus, eventually necrosed and was removed, the child making an excellent recovery. Photographs of the necrosed mandible and a skiagram showing the hard bone formation are given. Mr. Claude G. Colyer writes on Periodontal Disease, and Mr. H. E. Fullerton records a case of Cobalt Poisoning, the drug having been used to devitalise the pulp of a tooth.—The issue for April 1st contains a paper on Dental Education by Mr. W. Simms. The author favours the establishment of a representative dental council to control and overlook dental education. He considers that there is no subject included in the present curriculum which could be eliminated as unnecessary. With regard to the teaching in dental mechanics in the schools, he considers that there is a lack of constant authoritative supervision, and he advocates the appointment in dental schools of at least one individual who would devote his entire time to the development of dental science and teaching. Mr. David Rankin contributes a paper on Affections of the Naso-pharynx which cause deformation in and about the mouth.

CREMATION SOCIETY OF ENGLAND.—The annual general meeting of members of this society was held on April 7th in the West Lecture Hall of the Royal Society of Medicine. The President, Sir Charles Cameron, Bart., M.D., took the chair, and in his opening remarks pointed out that the society did not complain of the stringent precautions which were enacted in the case of cremation, but they did protest against the exclusive application of these to cremation, while nothing was done to remedy the scandalously lax requirements of the burial laws. The annual report for the past year, which was approved and adopted on the motion of the chairman, showed that during 1913 the total number of cremations carried out in Great Britain was 1183, as compared with 1134 in 1912. Of these more than half took place at Golders Green. Dr. Herbert T. Herring proposed and Sir John Tweedy seconded the election of Sir Malcolm A. Morris as a member of the council, and this was carried unanimously. On the motion of the chairman, the names of 21 persons who have rendered distinguished service in the cremation movement abroad were submitted to the meeting for adoption as honorary members of the society, and this was also carried unanimously, while a vote of thanks was accorded to the Royal Society of Medicine for lending their hall. Mr. Evan [illegible] proposed a vote of thanks to Sir Charles Cameron. Dr. James Stewart, in seconding, said how much any reform movement depended upon its figure-head, and the society was to be congratulated upon having such a man as its President.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

OPTOCHIN.

(WIDENMANN, BROICHER, AND CO., LIMITED, 1, FENCHURCH-AVENUE, LONDON, E.C.)

Optochin is the name given to a white crystalline powder which is the chloride of ethyl-hydrocuprein. Ethyl-hydrocuprein is a derivative of quinine, which it resembles in regard to its chemical reactions. Optochin hydrochloride dissolves in water, forming a blue fluorescent solution when acidified with sulphuric acid. Caustic soda precipitates the base, which is soluble in chloroform. The solution also shows the green colouration characteristic of salts of quinine when treated with chlorine and ammonia. Ethyl-hydrocuprein differs from quinine in containing a C_2H_5 instead of CH_3 group, and there are present also two more atoms of hydrogen in the basic group. Recent chemico-therapeutic researches have shown this preparation to have a remarkable check action in pneumococcal infection, and a series of cases is quoted illustrating the applications of the drug in pneumonia and ophthalmic practice. It is administered in doses of from 1½ grains to 7½ grains by the mouth, the daily dose not exceeding 22½ grains.

VIROLAX.

(VIROL, LIMITED, 152 TO 158, OLD-STREET, LONDON, E.C.)

Virolax offers an agreeable means of administering liquid paraffin for laxative purposes. It has the appearance of concentrated malt extract, and the microscope shows that the mixture is perfectly homogeneous. On the addition of water it turns milky, due to the separation of oily globules. It has an agreeable flavour, and the presence of some lemon juice is an advantage in this connexion. There are present the constituents of the well-known restorative food virol. The moisture amounted to 10·19 per cent. and the mineral matter to 1·19 per cent. Analysis gave 36 per cent. of total unsaponifiable oil (petroleum).

CANADIAN CLUB WHISKY.

(HIRAM WALKER AND SONS, LIMITED, 20, COCKSPUR-STREET, TRAFALGAR-SQUARE, LONDON, S.W.)

This whisky has characteristics of its own which distinguish it from the distilled products of Ireland and Scotland. The flavour is peculiar, but the whisky is smooth to the palate, bearing evidence of a matured spirit. Its analysis presents also some differences compared with Irish or Scotch whisky. Thus the higher alcohols commonly known as fusel oil occur to a far less extent, and the furfural amounts to about a third of that present in all-malt pot-still whisky. The amount of secondary products found in 100,000 parts of alcohol present were as follows: aldehydes 13·2, furfural 1·30, ethers 84, and higher alcohols 80 parts. The amount of alcohol present was a little over 50 per cent. by volume. The extractives amounted to 0·17 per cent., and these contained some tannin and a substance which reduces Fehling's solution. The volatile acidity reckoned as acetic acid amounted to 0·042 per cent., the fixed acidity reckoned as tartaric acid to 0·0075 per cent., and the mineral matter to 0·04 per cent. The character of the extractives indicates storage in cask, and thus justifies a statement made to this effect.

(1) "TABLOID" OPHTHALMIC ZINC SULPHATE COMP.; (2) "TABLOID" HYPODERMIC EMETINE HYDROCHLORIDE; (3) "VAPOROLE" EMETINE HYDROCHLORIDE.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

(1) The tabloid ophthalmic zinc sulphate provides an obviously useful formula in ophthalmic practice. It contains zinc sulphate 1/5th grain, boric acid 1/20th grain, tincture opium 1/15th minim, and epenine, the synthetic hæmostatic behaving like suprarenal extract, 1/10th grain. The formula has been particularly valuable in relieving painful and troublesome conjunctivitis caused by dust, as, for example, in the case of motorists and others. (2) The tabloid hypodermic emetine hydrochloride introduces a new strength of this drug, which contains 1 grain of the salt; and (3) the sterile solution (vaporole) also contains 1 grain in a convenient form for hypodermic injection. It is desirable, of course, in employing this remarkably useful drug in the treatment of amœbic dysentery to determine and to secure its accurate dosage.

STANDARD PHARMACEUTICAL PREPARATIONS.

(MESSRS. CORBYN, STACEY, AND CO., LIMITED, 673, COMMERCIAL-ROAD, LONDON, E.)

We have received from the above firm some specimens of pharmaceutical preparations manufactured under certain modified processes that add to the elegance of the product, while preventing a loss of therapeutically active principles. They are standardised in accordance with the requirements of the Pharmacopœia. Amongst the preparations which we examined were tincture of opium and tincture of ergot, both of which are perfectly bright and permanent fluids. Other preparations were an infusion of buchu and of gentian, both of which are concentrated, and for use require dilution to 1 in 7.

UNG. "CYCLOFORM" (BAYER).

(THE BAYER COMPANY, LIMITED, 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

This is a yellowish-white homogeneous ointment contained in a collapsible tube, and its chief application appears to be in hæmorrhoids and pruritus. Its suitability for such purposes will be understood from its composition. The ointment basis contains some zinc oxide, but the important constituents are cycloform (the iso-butyl ester of para-amino benzoic acid), a local analgesic, and extract of witch hazel, well-known as a styptic and astringent.

ULTRA-VIOLET RAY WATER STERILISER.

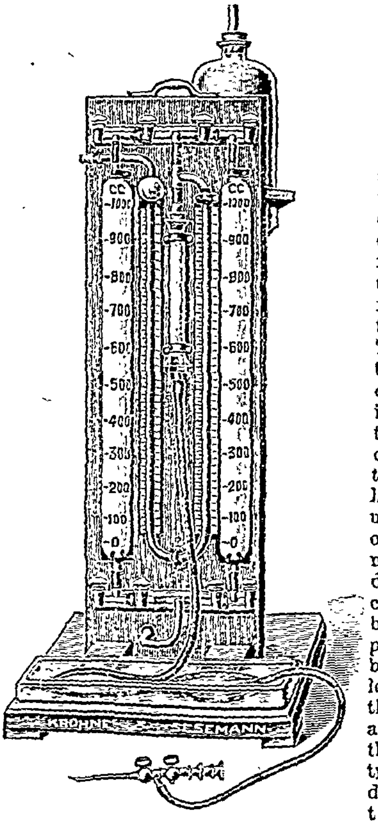
(THE WESTINGHOUSE COOPER HEWITT COMPANY, 80, YORK-ROAD, KING'S CROSS, LONDON, N.)

This ingenious apparatus provides for a regulated flow of water under a bombardment of ultra-violet rays from a powerful quartz vapour mercury lamp. There is an automatic cut-out which comes into operation should the lamp go out. This we found to work quite satisfactorily. The maximum capacity of the apparatus is about two litres per minute. The makers state that this type is suitable for industrial use and may be employed in schools, business premises, or factories. The water, of course, undergoes no perceptible chemical change. We have made experiments in regard to its sterilising power, and the results were striking. A heavily infected water was employed, the control showing on gelatine plates 6400 organisms per c.c. In the first experiment the rate of flow was 500 c.c. in 50 seconds. Bacillus coli was present in 1 c.c. of the ingoing water, but the total number of organisms found in the effluent was 23 per c.c.; there were, however, no bacilli present in 100 c.c. In the second experiment the rate of flow was increased, that is to say, to 500 c.c. in 25 seconds; the total organisms per c.c. was 38, but again bacillus coli was not present in 100 c.c. These experiments show, apparently, that the bacillus coli is quite killed off. The complete annihilation of bacillus coli and the reduction of from 6400 to 38 organisms per c.c., illustrate the remarkable bactericidal action of ultra-violet rays.

New Inventions.

A GAS INJECTING APPARATUS.

THE illustration shows a new form of apparatus which is now in use at the Pinewood Sanatorium, Wokingham, for injecting nitrogen or oxygen gas into the pleural cavity. Hitherto I have used, for the production of artificial pneumothorax, Morriston Davies's first modification of Kornmann's apparatus. This I have simplified as follows:—*a.* Two 1000 c.c. cylinders are provided, one for oxygen and one for nitrogen. Each has a "T" connexion both above and below, with a simple tap on each side. The upper outside tap is opened for filling with gas; the upper inside tap for allowing the gas to pass to the needle. The lower outside tap is for emptying only; the lower inside tap for letting the water pressure on to the gas in the cylinder. This last is the only one utilised once the operation is commenced. *b.* The displacing fluid is contained in a large bottle reservoir placed on a shelf behind, above the level of the top of the gas cylinders, and connected to them below by a tube which runs down the back of the stand. *c.* A glass tray is provided to hold the tube and needle. *d.* A second tap has been added to the needle, thus giving complete control in case of emergency without taking the hands off the needle.



The controlling taps on the apparatus (the lower inside ones) are not comfortably accessible as shown, and should run from before back instead of from above down. With this alteration the apparatus will be found to be very easily worked, and to be as nearly as possible fool-proof.

The apparatus is made by Messrs. Krohne and Sesemann, Duke-street, Manchester-square, London, W.

F. KINCAID ETLINGER, M.R.C.S. Eng., L.R.C.P. Lond.

Wokingham.

THE MEDICAL, SICKNESS AND ACCIDENT SOCIETY

Sixth Quinquennial Valuation, 1913

Sickness Fund: - - Rate of Interest assumed - - 2½%
Surplus £11,352. Bonus recommended as follows:
At age 65, £10 10s. for each £1 1s. per week sickness benefit insured, with a proportionate amount at death before 65.

Life Assurance Fund: Rate of Interest assumed - - 3%
Surplus £5,668. Bonus recommended as follows
25 % on all Policies becoming claims during next quinquennium.

Total Funds: £255,000. **Claims Paid: £200,000.**

No agents are employed, nor any commission paid for new business. All the profits belong to the Members.

The Medical Man's Society

The Society's policy is unquestionably the best obtainable, granting as it does the greatest benefits at the lowest rates compatible with security. Controlled by, consisting of, and founded exclusively for Doctors. For full prospectus write the Secretary.

IODARGOL

The Specific of Gonorrhœa, Acute or Chronic.

A Few Clinical Results.

2 Cases of Acute Gonorrhœa:

We deem it our duty to draw attention to this action of **Colloidal Iodine,** since it brings about a rapid and certain cure in gonorrhœa and causes a disappearance of the gonococci, without in any way interfering with the integrity of the organs.

DRS. MIETTE and TRUFFIER.

A Case of Gonorrhœal Follicular Urethritis:

It has seemed to us of some interest to report this case on account of the result obtained, and above all on account of the means employed for attaining it, for follicular abscesses of gonorrhœal origin, however they may start, always sooner or later acquire chronic symptoms, and we have never so far seen any but surgical treatment leading to a certain cure.

The success which has attended our urethral dressings with **Colloidal Iodine** seems to give some promise that the necessity for the radical methods of surgical treatment in cases of urethral folliculitis of gonorrhœal origin may be somewhat reduced.

By MARCEL DESCHAMPS, late House Physician, Assistant to Dr. BAZY, of the "Hopital Beaujon," and JEAN PERRIGAULT, late House Physician of the Infirmerie Centrale des Prisons.

Chronic Urethritis. Subacute Urethritis. Very Acute Urethritis.

We are therefore justified in concluding that **Colloidal Iodine** should be accorded **front rank** among anti-gonorrhœal agents, as much on account of the value and rapidity of its action as on account of its absolute harmlessness which allows us to administer it without the slightest fear of any complication arising owing to its use.

DR. GERALD BEXLER NANCY, late Interne of the Hospitals

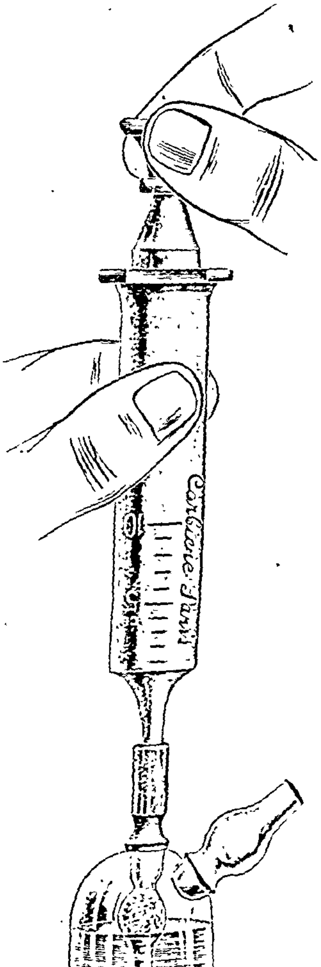
Samples and full clinical reports on application.

All Glass 10 cc. Syringe FREE

to Medical Practitioners wishing to experiment.

"AMPSALVS"

(REGISTERED)



THE MOST SIMPLE,
THE MOST CERTAIN,
THE MOST ECONOMICAL

Apparatus for the **instantaneous preparation** of an aseptic solution of **NOVARSENOBENZOL (Ehrlich's 914) for its aseptic filtration and for its direct aseptic entry into the syringe.**

With our "AMPSALVS" a strictly aseptic intravenous injection can be administered in two or three minutes without any complicated manipulation.

For the General Practitioner such an Injection offers no more difficulty than an ordinary Intravenous Injection does.

PRICES TO THE PROFESSION of our patented "Ampsalvs," containing 914 and doubly distilled water, free from air:—

"Ampsalvs," containing—

0·30 grm. (4 grs. 50) ...	6s. 0d.

THE LANCET.

LONDON: SATURDAY, APRIL 18, 1914.

Medical Aid Institutes.

IN the Supplement to the *British Medical Journal* of Saturday, April 4th, there is published a memorandum by the joint Medico-political and Hospitals Committees of the Association concerning the question of medical aid institutes, and it merits the close attention of the medical profession. The memorandum defines roughly what is meant by a medical institute as follows: It is an association which provides medical attendance for subscribing members, as a rule through whole-time medical officers paid by salary, and which collects regular contributions from its members, either directly or by deduction from wages. The memorandum proceeds to trace the origin of these institutes, quoting their early history as given in the investigations undertaken by THE LANCET 19 years ago under the title of the "Battle of the Clubs." Those articles, written under this collective title by our Special Commissioner, showed clearly that persons by joining such institutes could obtain medical service upon a more or less charitable basis to which they were not entitled owing to their pecuniary position, while further investigation proved that the membership of the institutes was recruited by a system of canvassing which brought their medical officers into an unprofessional and unethical position. Some of these officers were actually sweated, being entirely at the mercy of lay organisations, which paid inadequate salaries and retained money due to the medical profession, inasmuch as it had been received in return for medical benefit and earned by medical effort. The attitude of the medical profession towards these institutes, when their real meaning and the abuses that were rife under them had been made clear, rapidly became one of general antagonism. This is not to deny that sometimes the institutes were quite properly managed, for often the managing committees and the members of these institutes were on perfectly good terms with their medical officers. There is no desire to conceal the fact that a certain number of medical men, and, curiously enough, not always the best paid, appeared to be perfectly satisfied with their plight, while in some cases medical men frankly allowed that employment by the institutes was very serviceable to them. But the fact that here and there the institutes appeared to work satisfactorily had no weight in general professional opinion against the view that such working for laymen under contract was an inherently vicious scheme. The medical officers of these institutes were, as a rule, badly paid; they were at the beck and call of lay employers; and they were asked to undertake a mass of work which it was certain could not be properly discharged under modern conditions of scientific medical practice. Such was the feeling among medical men when the scheme for national insurance was first made public, and the most valuable argument which Mr. LLOYD GEORGE could bring forward in support of the National Insurance Act was the abolition of the abuses existent under contract practice of this sort, even though panel practice under the Act could not appear in any other guise than as a vast extension of contract practice. One of the main promises of the Act, as set out by the promoters of the legislation, was the introduction of a state of affairs under which the medical practitioner would receive what he earned, and would be free from lay control in professional affairs.

Until recently the medical profession has been content to believe that under the Act, free choice of doctor being allowed to insured persons, the danger of sweated medical service was overpast. The "Battle of the Clubs," however, is not yet won by the medical profession, and it is to prove this point that the memorandum in the supplement of the *British Medical Journal* has been issued. As is well known, medical institutes which were in existence at the passing of the Act have been permitted to provide medical benefit to their members, subject to the approval of the National Insurance Commissioners. There are as yet not many of these institutes; Wales and the Welsh border appear to be their principal home. But it is necessary to recognise that under the amendment in question any of the old medical aid institutes may be resuscitated, and, if the organisers of the movement in this direction can obtain medical officers short-sighted enough to play into their hands, a serious condition of affairs may be brought about. Last November[1] our Special Commissioner, in the course of reporting upon medical practice under the National Insurance Act in various localities, pointed out that at Chesterfield serious competition had been set up against the medical men upon the panels of the National Insurance Act by a district medical association definitely formed to compete with them. The Chesterfield District Medical Association, working under Section 15, clause 4, of the Act, had recruited many insured members to what was essentially one of the old medical institutes, and according to our Special Commissioner had not been particularly scrupulous in the methods employed. At the time when he wrote the Chesterfield Medical Association had upon its books a large number of patients who, under the generally understood meaning of the National Insurance Act, should have been panel patients, and the needs of these patients were being met by an inadequate medical staff. A similar condition of things he found to have arisen at Derby, where it was estimated that about 4000 patients, of whom half were insured under the National Insurance Act, were members of an Amalgamated Friendly Societies Medical Aid Association and were attended by medical officers employed by that association; the members whereof were thus unable to exercise the free choice of doctor which was promised under the Act. At Swansea a similar movement owed its failure probably to the strong action of the Swansea Division of the British Medical Association, and in particular to the refusal of the staff of the Swansea General Hospital to treat patients, except in cases of grave urgency, that were not sent to them in the ordinary way by panel practitioners. On this point the memorandum of the joint committees of the British Medical Association states that although they do not consider the position of the present institutes strong, yet "they are bound to regard the recent tendency to the spread of 'systems' in South Wales as a real danger unless a more active attitude of opposition to all such institutions is adopted by the profession throughout the country."

---

[1] THE LANCET, Nov. 15th, 1913, p. 1373.

We cordially agree with the memorandum, but cannot believe that the mischief will spread. For this reason we suggest that overt moves against practitioners who choose to take the pay of medical institutes will be attended with some risk. Chesterfield, Derby, and the South Welsh districts have revived the old club evils; more enlightened communities see the comparative advantages offered by the medical service of the panel practitioners. We do not anticipate much backsliding, relying here upon the good sense of the Commissioners in the advice that they will be called upon to give to the Insurance Committees. Our Special Commissioner's reports upon the working of the Act are at the present moment dealing with London, and he has nowhere recorded any organised attempt on the part of medical aid institutes to defeat the object of the Act or to oppose the working of the panels; and in the article next to appear, which deals with panel practice in Stepney and in such a typical outlying district as Enfield, he states expressly that both the public and the medical profession appear satisfied with the conditions under which medical benefits are administered.

The Need for Inspection of the Slum Laundry.

THE importance of the laundry as a sanitary institution can hardly be exaggerated, but it is, of course, desirable that the operations should be conducted within a sanitary environment. This can be managed with power laundries where facilities for keeping a clean bill of health exist, but where the work is done by hand sanitary requirements are often neglected. When the linen is sent to be washed at a power laundry the risk of the things receiving infection of any kind is comparatively small. The premises are used for no other purpose but laundering and are kept reasonably clean; there are no children running between the laundry and the school, interchanging infections; the workers employed are kept under scrutiny by the manager; whilst in his own interest the manager or proprietor is very careful not to accept soiled linen from any house where epidemic disease is in progress. Moreover, linen treated at a power laundry passes through processes which should go a long way towards sterilising it. The linen is treated in a closed machine, where, after a short preliminary soaking, it is washed with soap and soda at a low temperature; then boiled with fresh water and more soap and soda; then rinsed three times, the machine containing from 30 to 60 gallons of clean water for each rinse, so that 100 to 200 gallons of water are used for washing each machine load of linen. Suitable rooms for ironing and packing are provided usually, for a large number of power laundries have been built and equipped specially for the work they have to do; and it is an axiom of good laundry practice that the clean linen should never come into the neighbourhood of the soiled linen at any part of its career through the laundry.

In a well-equipped hand laundry the conditions may be satisfactory—it would be a very formidable state of affairs otherwise. The packing and sorting are often done under careful arrangements, and the linen is boiled in a copper; but there is not the facility for rinsing possessed by the power laundry, and, as the premises have not usually been designed for the purpose, it is more difficult to keep the clean and soiled linen rigidly separate. But below the level of the well-conducted hand laundry there are the small laundries of washerwomen who take in work from perhaps half-a-dozen customers, where all the rules of hygiene are ignored. Between these so-called "cottage," but in reality "slum," laundries and the well-conducted hand laundry no comparison is possible. They are commonly situated in some corner in a back street, and there is usually no sign by which they can be distinguished from the adjoining houses, except, perhaps, in dry weather, when some linen is hung out in the backyard. The house itself is usually old and more or less dilapidated. The work is carried out as often as not in the rooms where the proprietors live and sleep. The workers take their meals in the midst of the clean and the soiled linen, and in wet weather the washed linen is hung up to dry in the living and sleeping rooms. The workers themselves often belong to a low class, and there are sometimes numbers of children running about the place. No attempt is made to keep the clean and soiled linen from close proximity, nor is it possible to do so. The proprietors of the establishment are poor, and if infectious disease should appear in the house it is, where possible, carefully concealed, because its disclosure would entail loss of livelihood. And whereas in the case of a properly equipped and conducted laundry linen from an infected house would be rigidly excluded, the temptation to take such linen at a good price would be too great to be resisted by one of these slum laundries. There are even worse conditions obtaining in some slum laundries. In large towns where public washhouses are provided by the municipality for the benefit of working-class women who possess no conveniences for the purpose in their own homes, these washhouses, the cost and upkeep of which are paid for out of the rates, are employed by professional washerwomen who take their customers' goods there. These women often live in the most wretched surroundings, and after the linen has been washed in the municipal washhouse it is taken back to the dangerous dwelling to be ironed and finished. These facts are notorious at every public washhouse, and municipalities are making efforts to cope with the evil by instituting an ascending scale of charges for the use of the washhouse after the first few hours, so as to discourage the professional washerwoman, but the evil still remains. And that the danger is not theoretical is known to medical men, for cases of the spread of epidemic disease have been definitely traced on many occasions to the insanitary conditions of the premises occupied by washerwomen.

It is clear that the average housewife cannot protect herself or her household. Very few women realise the risk they are running in respect of their arrangements for the family wash, or take the trouble to visit the premises of their washerwomen. All they usually know is that a cart or, perhaps, a barrow comes to the door, takes the soiled linen away, and in due course brings the "clean" linen back. So long as it is returned at the expected time, looking sufficiently clean, and the price for the washing is reasonable, all appears well. It is certain that better protection is required than can be afforded by the care of the householder. The Factory Act is useless here, because in the first place it only deals with questions of hours of employment, guarding of machinery, and sanitary conditions so far as the workers are concerned, although incidentally the inspection under the Act tends always to the raising of the general standard of hygiene. But these little unhygienic laundries barely come within the scope of the Act, and both in theory and in practice they entirely escape any kind of inspection. They are on no register, and their very existence is unsuspected even by municipal authorities. At the Home Office and the Board of Trade it is generally known that the staff is numerically incapable of dealing with more than the power laundries and the larger hand laundries which are readily open to inspection. At the inquiry before the Select Committee of the House of Commons last year into the proposal to apply the Trade Boards Act to certain departments of steam laundries, the Board of Trade admitted that it was impossible to undertake the gigantic task of the regulation of all laundries. It was even declared that the subject was so large that it was only proposed to deal with two departments of steam laundries, whilst other laundries were quite out of the question. Judging from the answer given by Mr. JOHN BURNS to a question in the House of Commons recently, the bureau over which he now presides is still of the opinion that inspection of all laundries cannot be undertaken. Let it be admitted then that the little laundries are so numerous that it would be out of the question for a Government department to deal with them directly: then the proper way of approaching the matter is through local authorities. To continue to do nothing is wrong. The necessity for the prevention of the evils consequent upon insanitary laundries is urgent. No time should be lost in making and enforcing regulations ensuring that persons who take in washing for profit, even if it be only for one customer, should be registered at the office of the local sanitary authority, and obtain a certificate from the medical officer of health that the premises and working conditions are hygienically satisfactory.

Procedure in the Coroner's Court.

THE comments made by Mr. Justice ATKIN upon the procedure followed by the coroner at the inquest on the poor boy STARCHFIELD raise issues wider than those of the actual incident. The learned judge expressed his disapproval of several steps that were taken, including the putting of leading questions to witnesses, the signing of depositions by the latter at their houses, and the fact of their being allowed to make corrections in the written copies submitted to them. For several reasons the strictures appear to have been based upon unfamiliarity with coroners' courts and were unduly severe, especially when applied to a coroner with a reputation so high as that of Dr. WYNN WESTCOTT, with a period of 30 years' admirable service to his credit. In the first place, Mr. Justice ATKIN seems to have assumed that definite rules of procedure for the examination of witnesses exist in the coroner's court, whereas it has frequently been admitted by judges of the High Court that the law of evidence need not be observed during the conduct of an inquest. Again, the coroner is only bound by the Coroners Act, and while this Act requires that depositions shall be signed by the witnesses and by the coroner, it does not say that they must be signed "in court." The procedure adopted may have been unusual, but it was not illegal, and was followed in this case, we can readily believe, for the purpose of economising time. The evidence was taken down in shorthand, and it was necessary to transcribe this before it could be signed. If the statements of the witnesses had been taken down in longhand, the inquest, which as it was lasted for three days, would have been seriously prolonged. But perhaps the point deserving closest attention is the assumption underlying the whole of Mr. Justice ATKIN'S criticism of Dr. WYNN WESTCOTT'S conduct, that more or less rigid legal procedure can be observed in the coroner's courts. The learned judge does not appear fully to have realised the difficulties attending a preliminary inquiry where almost nothing is known of the circumstances at the commencement. At a trial in the High Court counsel has details of the alleged occurrences in his brief, and can obtain information from witnesses without putting leading questions; while the witnesses have already gone through several examinations and know what questions are likely to be put by their own side, and have their answers more or less clear in their minds. But the coroner has no prepared brief; he may know little or nothing of the evidence that is going to be adduced, and his inquiry must necessarily be more or less of a "fishing" character. Add to this the fact that he frequently has to deal with ignorant and illiterate witnesses who, if not closely questioned, might omit essential facts as seemingly unimportant, and it will be realised that the eliciting of a connected story with strict avoidance of leading questions would be a cumbersome and difficult process. And in the inquest on the boy STARCHFIELD, whether the procedure was irregular or not, no substantial effect was produced upon the course of justice, for the prisoner was committed by the magistrate and was tried on the magistrate's warrant. Moreover, the Recorder, in his charge to the grand jury, expressed the opinion that the case was a proper one to go for trial.

The question as to what rules of evidence should prevail in the coroner's court leads up to a larger question—What is the essential purpose for which an inquest is held? This question was very fully discussed at two meetings of the Medico-Legal Society last year, and the debate will be found in Vol. X. of the Transactions. At these meetings it was pointed out that while the original function of the coroner was to collect the KING'S revenues and to inquire into deaths for the purpose of ascertaining whether or not there was property which escheated to the Crown (which would occur if the deceased was an outlaw or felon), these duties, except in the case of treasure-trove, have now disappeared, while nothing has been definitely substituted for them. The evidence which was given before the Departmental Committee on Coroners' Law showed that most coroners consider their chief function to be the detection and prevention of crime; on the other hand, many attach equal, if not more, importance to the medical and scientific side of their inquiries. Recognition of the fact that a coroner has both legal and medical duties has led to the practice during recent years of appointing to the more important coronerships men who have had trainings in both law and medicine. But this only partially meets the difficulty. If the inquiry into the circumstance of a death is essentially for legal purposes, perhaps in connexion with crime, and perhaps in relation to questions of compensation, it may be convenient that the laws of evidence should prevail, and that legal procedure should be followed, but even here many coroners would prefer that the evidence should be tendered in any manner which makes for the discovery of truth.[1] On the other hand, if the chief object of the inquest is to determine the pathological cause of death, the coroner should be a medical man and should be entirely free to take any evidence he may think of value. Always the dual nature of the coroner's duties and responsibilities has to be thought of.

Of course, both aspects of his functions are of the highest importance to the community, but without expressing any strong opinion as to which should be adopted as the guiding principle, it may be pointed out that the legal side is already fully dealt with by other tribunals, while the medical side is scarcely provided for at all. The magistrate conducts a preliminary inquiry in accordance with the law of evidence into charges of murder. The existing double inquiry may be superfluous or actually prejudicial to the cause of justice —the risks have to be balanced against the added opportunities for getting at the truth. The jury at the trial may be biased by the fact that a definite verdict against the prisoner has already been returned at the inquest, and they may, through the medium of the newspapers, have become cognisant of matters which they ought not to know, which have not been legally established, and would not have been brought out at an inquiry where the law of evidence prevailed. Again, the coroner's verdict does not settle claims for compensation, and such questions must be investigated *de novo* in the county courts and higher courts. But the importance of obtaining scientific information relating to the pathological conditions underlying deaths from causes other than natural steadily increases. Such information is wanted for legislative and administrative purposes in connexion with the prevention of industrial diseases, accidents, overlying, improper feeding, and other causes of infant mortality. It is also urgently needed for the advancement of scientific medicine. It is understood that sooner or later the Home Office will introduce a Bill for amendment of the Coroners' Law. We venture to express the hope that before framing their measure they will consider carefully the two aspects of an inquest, so well and terribly illustrated in the STARCHFIELD case, and will endeavour to increase the usefulness of the inquest as a means of obtaining scientific knowledge.

Annotations.

"Ne quid nimis."

ETHERISATION BY COLONIC ABSORPTION.

IN 1847, the year in which Sir James Young Simpson revealed the possibilities of chloroform to a world expectant of the ultimate conquest of pain by the inhalation of anæsthetic vapours, Pirogoff, the great Russian surgeon, then in his thirty-seventh year, declared that the system of pulmonary anæsthesia would soon be wholly superseded by rectal etherisation! Roux was equally enthusiastic, but Magendie was the first to indicate that injecting ether into the bowel was at least dangerous and would be usually fatal. The mishaps, and they have not been few, which were recorded by those who attempted to employ the rectal mucous membrane as the area of absorption, are explicable by the work of the great physiologist. When this method of introducing the ether vapour allows condensation into liquid to occur in the bowel, proctitis, meteorism and paralytic distension, even fatal ulceration of the mucous membrane, may occur. Buxton, who introduced the method into this country some 20 years ago, was alive to this danger, and guarded against it by devising a special apparatus which he believed prevented any liquid ether entering the bowel. However, other methods of promoting the entrance of ether by this route have been suggested. Arnd employs a 5 per cent. solution of ether shaken up in warmed saline, but the procedure has not proved wholly successful, and it is not certain whether it possesses inherent advantages over the direct introduction of ether vapour by a suitable apparatus. We possess at the present time possibilities, by using an electric motor, of propelling heated air mixed with warm ether vapour into the bowel in definite proportion and at a given rate. The most recent development of colonic etherisation we owe to Dr. J. T. Gwathmey,[1] an account of whose pioneer work in this direction appeared in THE LANCET last year.[2] His experiments made upon dogs convinced him that an oil and ether mixture offered a reliable means of introducing the anæsthetic by colonic absorption, and that this method obviated some of the assumed dangers of inhalational methods. We are often struck by the fact that each new suggestion with regard to anæsthesia is commonly heralded by somewhat alarming statements of the perils of the established procedures. However, Dr. Gwathmey's plea for colonic etherisation possesses claims more valid than those which rest upon mere depreciation of the older methods of giving ether. Although his experiments and hospital cases have been free from dangerous complications, he frankly draws attention to the possibility of such occurring, due, as he pertinently puts it, to the extreme simplicity of the method and of the technique by which it is put into practice. It is necessary to cleanse the bowel, and this having been carefully carried out, the technique consists of injecting into the rectum one hour before the operation a mixture of 2 to 4 drachms of ether with an equal amount of pure olive oil in which are dissolved 5 to 10 grains of chlor-butyl. Then half an hour before the operation a hypodermic injection of morphine and atropine is given. Fifteen minutes before the operation the patient is placed on his left side in a modified Sims's posture and a mixture of 75 parts of liquid ether well mixed with 25 parts of olive oil is slowly introduced into the bowel by means of a rectal tube 28 inches in length with a diameter of one-fourth of an inch; this is clamped and fed from a glass funnel connected with a Lockwood tube 30 inches in length and three-eighths of an inch in diameter. One ounce is required for each 20 lb. of the patient's body weight, and this quantity (℥i) is injected each minute until the requisite amount has entered. As in the case of rectal etherisation by ordinary methods, the utmost care has to be taken to secure the patency of the air-passages, while should evidence of over-narcotisation appear the bowel is emptied of the ether mixture and the colon irrigated with oil or cold water to excite expulsive action. Massaging the colon from right to left assists in expelling the ether-oil mixture. Dr. Gwathmey regards his experience and that of others who have adopted his procedure as being, so far, quite encouraging. Undesirable sequelæ have been absent in his personal practice, while although some dangerous cases have been reported, he believes these are due wholly to errors of technique or to neglect of obvious precautions. He states that he has had 200 successful cases, but adds that in 100 of these a supplementary inhalation anæsthetic was required because the ether-oil narcosis proved too light for these particular cases. No doubt wider experience is necessary to perfect the technique of what appears to be a method offering obvious advantages in suitable cases. However, it has yet to be seen whether, when a larger number of patients have been subjected to this procedure, dangers and difficulties may not arise such as we know to have arisen when extensive trials have been made of the older plans of achieving ether anæsthesia by rectal absorption. The bland nature of olive oil and its avidity for ether would, however, lead us to hope that such sequelæ may be absent in the method we have described. Dr. Gwathmey states that he is experimenting with other drugs besides ether for use by colonic absorption, but it is at present premature to discuss the possibilities these present or to offer criticism until our knowledge is more extended and more precise.

ALCOHOL AND LONGEVITY.

IT is frequently asserted by the more extreme opponents of the dietetic use of alcohol that the evidence of insurance statistics establishes beyond all cavil the advantages accruing to health from the practice of total abstinence. The ground for this assertion is the fact that insurance societies which have a separate section of total abstainers find that the mortality in that special class is considerably lower than in the general mass of policy-holders. For instance, in the United Kingdom Provident Institution, whose records are most often quoted in this connexion, the ratio of actual to expected claims, calculated over a considerable term of years, works out at 70·47 per cent. in the temperance section, while in the general section it comes to 95·14 per cent., and very similar results have been noted in the case of other large societies here and in America. Statistics of this sort are admittedly unbiased, and their accuracy will not, of course, be disputed. But what is by no means equally evident is the soundness of the conclusions founded on them by the advocates of total abstinence. In an article published in the *American Underwriter* for July, 1913, and now issued in pamphlet form,[1] Mr. Phelps, the editor of that journal, and a well-known authority on insurance questions, draws attention to what he very reasonably regards as the most serious source of fallacy in this particular statistical argument—namely, the possible differences in other respects besides drinking habits between the contrasted groups of abstainers and non-abstainers. As supporting his criticism, he quotes the results of an investigation carried out by Dr. Dwight, medical director of the New England Mutual Life Insurance Company, who found that total abstinence from tobacco appeared to have almost exactly the same relation to longevity as total abstinence from alcohol. This fact suggests the need of extreme caution before we assume that the lower mortality of total abstainers is wholly due to their avoidance of alcohol. Possibly we should be nearer the truth in adopting the view put forward tentatively by Mr. Phelps that abstainers, whether from alcohol or from tobacco, are as a class of somewhat different type or live under different, and on the whole less strenuous, conditions as compared with the general run of persons who indulge in these luxuries. At all events, it is clear that insurance statistics cannot be regarded as furnishing any legitimate ground for the assertion that the moderate use of alcohol is injurious to health, and the attempt to represent them as proving such a statement can only do harm to the cause of true temperance.

SKIAGRAPHY OF THE FALLOPIAN TUBES.

THE investigation of the ureter and pelvis of the kidney by means of X ray photographs following the injection of silver salts (collargol especially) is so successful and so generally practised by urologists that the extension of the same principle to the Fallopian tube must have occurred to gynæcologists as practicable. Dr. W. H. Cary, of Brooklyn, has carried out the idea, and reports his experience in the March issue of the *American Journal of Obstetrics*. In a patient who complained of continuous pelvic pain without any gross physical signs to account for it he injected 10 c.c. of collargol solution through the cervix under anæsthesia. He then opened the abdomen and found the solution oozing from the right tube, but none flowing from the left one. After freeing some adhesions the latter was removed; it appeared to be normal until dissected afterwards, when it was found to be completely occluded near the uterine end. This occlusion was well shown by the X ray photograph taken just before opening the abdomen. It is clear that this method, if it proves to be safe, may influence very markedly the diagnosis of the cause of sterility and its treatment in cases where Fallopian obstruction is shown to exist. The process is contra-indicated whenever recent pelvic inflammation or any form of infection exists. Dr. Cory suggests that at least three months of freedom from acute inflammatory symptoms should elapse before undertaking it. Retro-displacement of the uterus or prolapse of the adnexa may cloud the picture; the former should be corrected before the injection is made. The patient is placed in position with the X ray apparatus and plate all ready for action. By speculum and tenaculum the cervix is exposed and steadied. A glass intra-uterine instillation tube is passed through the os, which it should fit closely; the silver solution is then slowly injected and the skiagram immediately taken. The average content of the uterine cavity is stated at eight minims. It remains to be seen whether this procedure is free from risk, and also whether the collargol has any beneficial action on tubal infections.

THE VICTORIA HOSPITAL, BLACKPOOL.

THE regrettable dispute between the medical men at Blackpool and the board of management of the hospital appears to be no nearer a settlement. The circumstances out of which it arose were described in THE LANCET of March 21st, p. 867. Since then, at the annual meeting of donors and subscribers to the hospital, after a prolonged discussion a resolution, based upon a suggestion of Dr. T. Carr, was carried unanimously to the effect that the medical men of the town should appoint a committee of six to explain what reorganisation and changes the medical practitioners would be prepared to accept. At a subsequent meeting, however, of the medical profession practising in the town it was resolved to forward a letter to the board stating that until the medical men's demands for two seats on the board, for the resignation of the matron, and for the resignation of a medical practitioner still on the board were complied with, the medical men refused to meet the board. The letter was forwarded, and in reply the board has stated that the matron has resigned and that the board has received her resignation with regret, but that the board has no power to comply with the request for two seats, as its members are appointed by the donors and subscribers. The medical member of the board was appointed by the donors, and the board had, they said, no power to call for his resignation even if it wished. It would seem, and it is a matter for extreme regret, that a deadlock has arisen without full discussion and at a point at which discussion might have resulted in a way out of the difficulty being found. That the difficulty is one not easily to be arranged, even after each side has had the opportunity to express its views, is only too evident. The medical men on the one side possess full sympathy not only from the members of their profession, but from a large section of the lay public. They are seeking nothing for themselves, but primarily have espoused the cause of two nurses whose treatment meted out to them by the board, under the immediate observation of the medical staff of the hospital, has appeared to that staff to be harsh and unjust. It may here be said that from all accounts of that treatment which have been made public it was such as might well justify the attitude of the medical men, and it must be remembered that, whatever there was in the conduct of the nurses which the board resented, the dispute arose out of complaints with regard to the feeding of the nursing staff, as to the justice of which the medical staff was well able to form and express an opinion. Again, in connexion with the constitution of the board, the medical men of the town are certainly entitled to hold opinions, and to have those opinions carefully and sympathetically weighed by the subscribers to the hospital. At the same time, a board may naturally hesitate to admit itself at the outset of a discussion to have been wrong in the initial stages of the matter to be discussed. The affair has reached a stage at which every attempt should be made to bring about a settlement, and, if this cannot be obtained by the parties meeting, it may be suggested that they should refer their differences to arbitration. It should not be difficult, or at any rate not impossible, to find persons of experience in hospital management absolutely independent of local prejudice or interest, and having the necessary judicial qualities, who would be willing to give careful hearing to both sides, and be able to decide in the best interests of the hospital what the future constitution of its board should be—and this may now be regarded as the essential matter in dispute. A pronouncement as to the incidents which have been referred to in connexion with the nursing staff could be added. It would, however, be necessary for both sides to agree to abide by the arbitration.

[1] The Supposed Death-rates of Abstainers and Non-abstainers and their Lack of Scientific Value. By E. B. Phelps, M.A., F.S.S. New York: Thrift Publishing Company. 1913. Pp. 30.

A NEW CUTANEOUS REACTION IN PREGNANCY.

IT is now generally recognised that the process of gestation is associated with general changes in the organism as well as with the growth of the fœtus and the local alterations in the uterus. It has been proved that some of the glands with internal secretions show definite histological changes, and numerous observers have found that in pregnancy protein substances foreign to the normal blood are in circulation. Abderhalden has further proved that the organism produces defensive ferments to break such proteins down. He has applied this observation to develop a test for pregnancy, which is at present on its trial. The idea occurred to Dr. Ernest Engelhorn, of Erlangen, that it might be possible to demonstrate the presence of these substances by inoculation, on the analogy of the tuberculin reaction of von Pirquet, the luetin reaction of Noguchi, and the trichophyton reaction employed by dermatologists. As a consequence he has made some observations in collaboration with Dr. Hermann Wintz, and these are published in an interesting preliminary note in the *Münchener Medizinische Wochenschrift* of March 31st. Starting with the assumption that materials from the placenta must enter into the general circulation of the pregnant woman, they have prepared a placental extract to which they give the name "placentin." They do not give the details of its preparation, but simply state that it is a somewhat complicated process and that they are engaged in experiments with a view to its simplification. They have used this substance exactly in the same manner as tuberculin is employed in von Pirquet's reaction. The site of inoculation is inspected at 12, 24, and 35 hours afterwards. A positive reaction consists in an inflammatory swelling and reddening of the inoculated areas, with a light brown staining around them. In every case two places were inoculated with the placentin, a third line being simply scratched with the lancet as a control. In cases showing a positive result the reaction is usually most distinct after 36 hours. In 70 pregnant women the test was positive in every case, the pregnancies being of all stages from the second month to full term. The reaction was tried in 54 non-pregnant patients, including children and 13 men. In all adult persons it gave a negative result, save that in three women who were inoculated very shortly before the expected onset of the period a slight irritation of the inoculated area occurred, but so slight that in comparison with the reaction in pregnant women it could only be called negative. Dr. Engelhorn and Dr. Wintz point out that this result may be of some interest in the light of the recent observations of Kjaergaard to the effect that before the period there is an increase in the proteolytic power of the blood serum in women, and that the serum under these conditions may give a positive Abderhalden's pregnancy reaction. One peculiar result was obtained with the inoculations of placentin, in the case of a child, aged 6 years, with an affection of the bladder, the reaction being positive. The authors are now engaged in further investigations. They make no claim as yet for the practical value of their reaction as a diagnostic measure, but hold that it is at least of theoretical interest. It is, further, of some significance that very shortly after parturition a negative result is obtained.

THIRD INTERNATIONAL CONGRESS ON DISEASES OF OCCUPATION.

THIS Congress will be held in Vienna from Sept. 21st to 26th, and the arrangements in connexion with it are now being rapidly completed. In our own country a very powerful committee has been got together for the purpose of obtaining contributions and promoting efficient representation at the deliberations. The Home Secretary, the Right Hon. R. McKenna, is Honorary President; Sir Thomas Oliver, President; whilst the members are Sir John Collie, Sir Thomas Flitcroft, Professor John Glaister, Professor Sheridan Delépine, Professor Eurich, Dr. H. Langley Browne, Dr. J. Hedley, Dr. J. Dallas Pratt, Dr. W. Hamilton, Dr. F. Shufflebotham, Dr. Herbert Jones, Dr. C. H. Milburn, Dr. T. D. Lister, and Dr. R. W. Edginton. Dr. T. M. Legge is chairman of an executive committee, to which Mr. W. F. Dearden is acting as honorary secretary. The Home Office will be represented at the congress by Dr. Legge, and various medical associations have intimated their intention of sending delegates. Discussions will take place under eight separate headings, and papers which come within the scope of any of these are cordially invited. They are: (1) fatigue; (2) work in hot and humid atmosphere; (3) industrial anthrax; (4) pneumoconiosis; (5) effects of electricity industrially; (6) occupational poisonings—lead, &c.; (7) ill-effects of occupation on hearing; and (8) general communications. Papers will be printed in the language in which they are written, with an abstract in both French and German, and the general proceedings will be published in the two languages mentioned. Contributors are therefore requested to send their matter typewritten, along with an abstract. As translations will take a considerable time papers should be sent to the general secretary, Dr. E. Teleky, Turkenstrasse, 23, Vienna, IX., on or before May 1st. The meetings will be held in the House of Parliament, and there will be an exhibition illustrating the methods of preventing occupational disease adjacent. Although the subjects under discussion are treated from the medical aspect membership of the congress is not confined to medical men; any persons or association interested in this branch of study can attend the congress or subscribe for the proceedings. The subscription is £1. Those who wish to send in communications, attend the Congress, or take advantage of arrangements for combined travel and accommodation at a reduced rate, should communicate with Mr. Dearden at 168, Trafford-road, Salford, Manchester, at an early date.

RECENT RESEARCHES ON THE CONDITION OF THE CEREBRO-SPINAL FLUID IN NERVOUS DISEASE.

OUR knowledge of the intimate relations between certain nervous diseases and the condition of the cerebro-spinal fluid is steadily increasing, and recent investigations have served to bring some points into clearer light. It is known that normal fluid contains from 0·03 to 0·06 per cent. of albumin, which is made up of globulin and of albumose. In pathological conditions much more attention has been devoted to the globulin content than to the other; but the latter is undoubtedly often of diagnostic importance. Dr. A. Myerson, of the Taunton State Hospital, Massachusetts, discusses its significance in the March number of the *Journal of Nervous and Mental Disease.* A routine quantitative examination of the albumin content should never be omitted, though hitherto most observers have been satisfied with an investigation that does not go beyond the so-called "four reactions" (Wassermann test for the blood, the same for the fluid, the Nonne-Apelt globulin test of the latter, and the cytological condition). Dr. Myerson measures 2 c.c. of the fluid by a graduated pipette into a narrow test-tube: the fluid is then heated short of the boiling point, and 6 drops of a 33⅓ per cent. aqueous solution of trichloracetic acid are added. Normally a diffuse cloudiness appears, and after about half an hour a flocculent precipitate will have settled to the bottom of the tube, which it just covers. When there is albumin increase, however, a dense cloud appears which at once becomes flocculent, and may fill the tube to a depth of perhaps 0·5 cm. from the bottom. By employing identical quantities and tubes, and always using the same rigorously exact technique, it is easy to determine important differences between various cerebro-spinal fluids. Some of Dr. Myerson's results may be briefly alluded to. In general paralysis there is always a marked increase of albumin which is usually parallel to the globulin increase. During treatment by the salvarsanised serum method the albumin content varies to a much less extent than the Wassermann reaction, the cell count, or the globulin content, which suggests that albumin increase is a more constant sign of the pathological process underlying general paralysis than any of the other signs. In alcoholic polyneuritis and psychosis, the Korsakoff syndrome, those cases in which mental symptoms preponderate show greater increase in the albumin content than do those with more pronounced neuritic symptoms. There is in this condition a definite dissociation between the globulin and the albumin content, the former being little if at all increased. Other data are quoted which go to show that augmentation of the quantity of albumin in the cerebro-spinal fluid is an early and constant reaction in certain conditions, and the exact determination of its significance is a task worthy of neurological investigation. In a recent number of the *Nouvelle Iconographie de la Salpêtrière* Professor G. Marinesco and Dr. A. Radovici, of Bucharest, discuss the diagnostic value of the syndrome of xanthochromia and spontaneous coagulation of the cerebro-spinal fluid mentioned for the first time by Froin in 1903. By xanthochromia is meant a yellowish colouration of the fluid, due doubtless to the invasion of the subarachnoid spaces by blood pigment. Coupled with these two conditions is a third—viz., a practically normal cell count. The chief pathological states in the course of which the syndrome may occur are meningo-myelitis, compression of the cord, ascending paralysis, and generalised meningitis. In almost all the recorded cases there has been paraplegia either of spastic or of flaccid type. The level of the process may be high or low in the spinal cord. The explanation of the coagulation is to be found in the presence, in altogether abnormal quantity, of fibrinogen and fibrin ferment. These are not present in normal fluid, in which, for that matter, albuminoid substances occur only in minute quantity. It is probable that inflammation of the subarachnoid endothelium is one of the common causes of hyper-albuminosis of the fluid, but the latter may be provoked by other pathogenic mechanisms. Nonne considers that hyperalbuminosis with a normal cell count is pathognomonic of medullary compression from spinal tumour. The various pathological processes enumerated above have this in common for the production of the syndrome—that the subarachnoid spaces are invaded in such a way that a portion of the circulating fluid is isolated in a more or less closed cavity. Professor Marinesco and Dr. Radovici are of the opinion that minute capillary hæmorrhages, repeated at intervals, and an inflammatory state of the meninges are sufficient to account for the coagulation and the xanthochromia in most cases; in others—e.g., the tumour cases—toxins derived from them may irritate vascular surfaces, while stasis of the fluid favours fibrinous exudation. It is true that in cases of meningeal hæmorrhage the fluid withdrawn does not coagulate spontaneously, but the explanation is that fibrinous coagulation has already taken place at various points on the surface of the nervous system, and the fluid withdrawn has no fibrinogen in it, all of the latter having been deposited in the form of fibrin in the subarachnoid spaces.

CHANGES IN THE BASE OF THE SKULL IN PAGET'S DISEASE.

IT is a somewhat curious circumstance that since Sir James Paget's original description in 1876 of the disease which bears his name, the chief contributions to its study have emanated from continental schools. In the last number of the *Nouvelle Iconographie de la Salpêtrière* is a paper by Professor A. Léri, of Paris, which adds considerably to our knowledge of the cardinal clinical features of osteitis deformans. It has long been recognised that the disease is an osteopathy affecting more particularly the trunk, the long bones, and the cranial vault; but the idea that the condition is thus usually limited is erroneous. Alterations in the small bones of the hands and feet are far from uncommon, and Professor Léri has now demonstrated that certain changes in the base of the skull are not only constant but characteristic. His paper is based on the study of no fewer than seven cases, of which two are personal; the other five are those whose skulls are preserved in Dupuytren's museum in Paris. Further, Professor Léri has found identical appearances in the skulls from which Sir James Paget drew his description, skulls preserved in the museum of the Royal College of Surgeons of England. The alterations in the cranial base may be present, although the cranial vault is unaffected and although the long bones may reveal no pathological changes that are clinically discoverable. In the first place, there is hypertrophy of the bones of the base; as a result, the basal foramina, both vascular and nervous, are reduced in size. There is also a constant deformation of the base; this consists in an upward projection of the bones in the immediate neighbourhood of the foramen magnum. As a result of this alteration the anterior and middle cranial fossæ are deepened, while the transverse diameter of the cranial cavity is increased. This compensatory dilatation counteracts the loss of volume sustained by the cavity from diminution of its vertical diameter, hence its cubic capacity remains practically unaltered. Radiographic examination of the skull in cases of Paget's disease will determine the regularity with which such changes occur. The posterior fossæ are relatively shallow, and the upward deformation of the base ("convexobasie") results in a sort of levelling up of the base as a whole ("platybasie"). Further, the "orbito-petrous angle" formed by the orbital plate (posterior margin) in front and the superior margin of the petrous bone posteriorly is always more obtuse in the case of Paget's disease than in normal skulls, averaging 137° in the latter and 170° in the former. With these data it may be possible to come to an accurate diagnosis, though other signs of the disease are wanting. The suggestion is made that the diminution in calibre of the various basal foramina is responsible for some of the nervous, vasomotor, and trophic symptoms that occur in Paget's disease; the deformations of the base certainly explain some of the facial and other cranial changes recognisable by the clinical observer.

OX-GALL AS AN APERIENT.

THE use of ox-bile in medicine dates back to somewhat remote times. By the earlier physicians many virtues were claimed for it, but nowadays it is rarely prescribed. It is known, however, to be a valuable chologogue, and it is usual to administer it in capsules coated with keratin or in pills. At one time it was not uncommonly prescribed in the form of an enema as a purgative, but it is said to possess little or no advantage over soap, and latterly one seldom hears of the use of ox-gall in this form. But it is interesting to observe that in an address recently delivered before the Carlisle Medical Society Dr. William Murray referred to the remarkable aperient effects of ox-gall suppositories. They seemed, he said, to produce an easy, rapid, and effectual movement of the bowels in cases of constipation, their action being mollified by the addition of oxide of bismuth and intensified if administered in conjunction with the ordinary glycerine suppository. It would therefore appear that the aperient effect of ox-gall when administered in this form is much more pronounced than when it is applied in an enema, the explanation probably being that peristalsis is increased to a greater extent by the application of the substance in a solid form. A suitable suppository could be made with cacao butter, each suppository to contain, say, 5 grains of fel bovinum purificatum; if it were desired to produce the mollified effect mentioned by Dr. Murray 5 grains of bismuth oxide could be incorporated in each suppository. On the other hand, if it were desired to produce the intensified effect a suppository could be prescribed containing 5 grains of purified ox-gall with glycerine suppository as the base.

SPONTANEOUS RUPTURE OF THE TYPHOID SPLEEN DIAGNOSED AND TREATED SUCCESSFULLY.

THE operation of splenectomy has attracted a good deal of attention in recent times, and it is now possible to enumerate quite a formidable list of recognised indications for its performance. It is not altogether to be wondered at that these lists do not usually make any allusion to rupture of the typhoid spleen as one of the conditions in which excision of the offending organ is imperatively demanded, for it appears that this accident has only been recorded 13 times, and in nine of these as a surprise at necropsy. Four times it has been discovered during life, in three of these cases at an operation undertaken for supposed intestinal perforation, while in only one has a correct diagnosis been made and a successful splenectomy performed. The fortunate patient in this last case was a medical man aged 36, who came under the care of Dr. Lewis A. Conner and Dr. W. A. Downes in the New York Hospital, with a diagnosis of probable typhoid fever. He had been ill a week, and the day following admission was suddenly attacked by severe pain in the left hypochondrium and left shoulder. This was accompanied by vomiting with collapse; the left hypochondrium was rigid and tender, and the splenic dulness increased in area. The patient rallied for a day or two from these serious symptoms, the cause for which was not obvious, especially as at this time the Widal reaction was still negative. Two days later, however, the same symptom-complex reappeared with manifold intensity. The left side of the abdomen and the left flank were dull, but the rest of the abdomen was soft and the liver dulness was normal. A consultation resulted in a diagnosis of ruptured spleen, and the blood was examined to see whether it gave any indications of severe internal hæmorrhage, but without any positive result. However, an immediate laparotomy was performed, the first discovery being the presence of a large quantity of fresh and clotted blood (one and a half to two quarts) in the peritoneal cavity. The spleen was seized and delivered through the incision (a vertical one down the middle of the left rectus muscle), a large rent being found in its capsule along the posterior border. The pedicle was tied off, the spleen removed, and the abdomen closed rapidly. The operation, which was undertaken less than six hours after the onset of the second bout of symptoms, occupied no more than 20 minutes. The patient recovered well from the laparotomy, and the fever ran a normal course, though there were evidences of median basilic thrombosis with pulmonary infarction. There was a temporary anæmia with leucocytosis following the operation, but the blood picture gradually returned towards the normal. The excised spleen displayed nothing of note apart from a laminated clot on its diaphragmatic surface, of such an age as to support the belief that the first bout of acute abdominal symptoms was due to a rupture of the spleen prior to that which was the immediate occasion of the laparotomy. It is suggested by Dr. Conner and Dr. Downes that this second rupture was caused by coughing. It seems, therefore, that spontaneous recovery from rupture of the typhoid spleen is conceivable. This extremely interesting case, which is reported fully in the *American Journal of the Medical Sciences* for March, with a summary of the other cases referred to, constitutes a true advance in the art of healing; for the first time rupture of the typhoid spleen has been correctly diagnosed, and the patient's life has been saved by a timely splenectomy.

THE committee of the Cambridge Research Hospital is making a special effort to raise an endowment fund of £10,000, and the executors of the late Sir William Dunn, Bart., have, after giving special consideration to the needs and work of the hospital, sent a donation of £2500.

PLEA FOR AN INTERNATIONAL ANATOMICAL TERMINOLOGY BASED UPON THE B.N.A.

BY WM. CUTHBERT MORTON, M.A., M.D. EDIN.,
HONORARY DEMONSTRATOR OF ANATOMY, UNIVERSITY OF LEEDS.

THE present state of anatomical terminology in Britain is deplorable in the extreme. The German speaking anatomists, realising the importance of uniformity, spent much time and money in evolving for themselves a Latin nomenclature which since it was adopted in 1895 by a conference at Basle is known as the Basle *Nomina anatomica*, or for shortness the B.N.A. Although the B.N.A. was primarily intended for the use of the German speaking nations its authors hoped that it would in course of time be possible to "gain the coöperation of anatomists speaking other languages" and so to obtain a truly international terminology. In Britain, however, the B.N.A. had a chilling reception. This might have been excused had the British anatomists only taken the trouble to revise their own terms and evolve a uniform system for their own use. To this day the British nomenclature remains in a state of anarchy, and the anatomists are now divided into three camps: first, those who hold fast their faith in the national terminology and ask only to be left in peace; secondly, those who have become converts to the B.N.A. and would force it upon their brethren by the sword; and lastly, those who believe that there is much to be said on both sides, and are earnestly seeking a compromise. Each disputant sees the good in his own system and the bad in those of his rivals. Each demands what he himself does not think of giving—namely, a statement of guiding principles. This miserable dispute will never be settled by a comparison of details. A definite standard is needed for testing the rival systems. Principles must be formulated which will command universal respect and which, when applied to the details, will automatically winnow out the chaff and leave the corn. The British terminology is based upon no definite principles, and as for the B.N.A., if the statement of its principles given by Professor L. F. Barker, of Johns Hopkins University,[1] is even approximately correct, its authors must have thought, and many will agree, that such principles are almost as much honoured in the breach as in the observance.

An international terminology is a real necessity, and for this purpose there is nothing in existence to compare with the B.N.A. If little or nothing is here said of its merits, that is solely because they are, or at least by this time ought to be, sufficiently well known. The supreme defect of the B.N.A. is its lack of motive power to induce everyone to accept it even as a code. No international nomenclature can possibly command universal respect and be universally accepted unless it is broadly based upon sound and well-defined principles. Its language must be international and its terms both perfectly precise and strictly relevant. If it is to be comprehensive and concise, to be illuminating, or even, in some instances, merely intelligible, it cannot entirely dispense with duplicate terms. In each country the international terms may be employed unchanged, they may be nationalised in form, or they may be replaced by previously existing national equivalents. Though always equally lawful such synonyms will seldom be equally expedient.

Language.

For an international anatomical nomenclature Latin is without a rival, but to insist on Latin only or on Latin of a high order is sheer pedantry. It is futile to demand that "each term shall be in Latin and be philologically correct," and Professor Barker is manifestly blinded by admiration when he declares of the B.N.A. that "all the terms are in correct Latin." "Ventriculus" is Latin, "hepar" Greek, and "mesorectum" both and neither. Is it really worth while straining out gnats when whole troops of camels must be swallowed? It is indeed a sign of health in the B.N.A. that so little attention is paid to the *muscae volitantes* of philology.

Precision.

In these days when stars are accurately weighed in the balance and their distances measured with precision, is it too much to ask that a scientific terminology shall be precise and self-consistent? How many of the "nervi cerebrales" of the B.N.A. are in any sense cerebral? These nerves are attached to the brain and spinal cord, and they pass to and fro through foramina on the one hand in the cranium, on the other in the spinal column. It is convenient to distinguish between the two sets of nerves, and the British terminology quite accurately divides them into the "cranial" and the "spinal" nerves. In the B.N.A. the cranial nerves are termed "nervi cerebrales," which is obviously incorrect, since although the so-called cerebral nerves are all connected with the brain, the brain as a whole is not the "cerebrum" but the "encephalon." To quote Cunningham's Manual in a slightly modified form, "*No fewer than eight of the*" 12 "*cerebral nerves have a superficial attachment,*" not to the cerebrum, but "*to the ventral part of the hind-brain which is formed by the medulla and the pons.*" During a recent discussion in the Anatomical Society of Great Britain and Ireland an eminent London anatomist proclaimed his unconquerable aversion to "the cerebral nerves." On what principle is he or anyone else to be condemned to employ a term so inaccurate? Again, in the B.N.A. the abdomen includes the abdominal wall as well as the abdominal cavity. How, then, can the exit from and the entrance to the inguinal canal be contrasted as the "annulus inguinalis subcutaneus" and the "annulus inguinalis abdominalis"? Again, the mesentery is generally agreed to be the μέσον, or middle thing, the medium or means by which the ἔντερον, or intestine, is attached to the posterior abdominal wall, yet its constitution and relation to the gut when they are not left to the imagination are variously described. If an international terminology is not to be a farce such diversity and vagueness must be made impossible. Each term (e.g., mesenterium) must have a definite content and neither it nor its national equivalents (e.g., mesentery, *mésentère*, and so on) must be used in any but the international sense. Certain British text-books are pluming themselves on their faithfulness to the B.N.A., but the strictest of the sect frequently ignore it both in principle and in detail. They speak of "the superficial fascia," "the frontal operculum," "the seventh cerebral nerve," "the innominate artery," "the pelvic girdle," and so on, whereas the most careful dissection of the B.N.A. reveals only "panniculus adiposus," "pars triangularis operculi," "nervus facialis," "arteria anonyma," "cingulum extremitatis inferioris," &c. It cannot be too strongly insisted on that the international nomenclature shall be precise and self-consistent and that the national terms shall precisely and consistently correspond to their international equivalents.

---

[1] Anatomical Terminology, with Special Reference to the B.N.A., by Lewellys F. Barker, Professor of Medicine, Johns Hopkins University, Baltimore (formerly Professor of Anatomy, Rush Medical College, University of Chicago).

Relevance.

Professor Barker gives it as a principle of the B.N.A. that "the terms shall be merely memory signs and need lay no claim to description or to speculative interpretation." Anatomy, it is true, contains many excellent terms of this character. The term "aorta," for example, could scarcely be replaced, yet how many ever trouble themselves over its origin and meaning? But although in certain cases the terms "need lay no claim to description or to speculative interpretation," they will, for the most part, be all the better even as "memory signs" if they are truly descriptive and can be readily interpreted. The B.N.A. itself to some extent recognises this, for Professor Barker states a further principle that "related terms shall, as far as possible, be similar—e.g., femur, arteria femoralis, vena femoralis, nervus femoralis." What is this but descriptive nomenclature clamouring for interpretation? The crux of the matter is that everyone desires not a mere code, but a terminology as far as possible descriptive and suggestive, and whereas unanimity might soon be attained were it only a question of labelling for identification, when it comes to description and suggestion it is *tot homines tot sententiæ*. In Britain the "appendix" has long been associated with the "mesappendix" and the "appendicular artery," whereas the B.N.A. has the terms "processus vermiformis," "mesenteriolum processus vermiformis," "arteria appendicularis." The latest edition of Cunningham's text-book, without a vestige of authority, replaces "arteria appendicularis" by "the artery of the vermiform process." If the B.N.A. is not to be rigidly adhered to, how much more simple, concise, and suggestive would be "vermiform appendix," "mesappendix," and "appendicular artery." This would also harmonise with the usage of pathology, medicine, and surgery, whereas no wormlike process of mental wriggling could ever lead one from the processus vermiformis to a catarrhal appendicitis or an appendicular abscess. Again, some anatomists speak of the "spinal," others of the "vertebral" column, some of the "gastro-hepatic," others of the "lesser" omentum. Which of these equally correct and equally suggestive terms are to be sacrificed to the fetish of international monotony? Though the recent adoption of the B.N.A. in certain British text-books has served the useful purpose of bringing matters to a head, such isolated action rather suggests the policy of the "big stick." Uniformity is never worth having by coercion or grudging concession. "Cabin'd, cribb'd, confin'd" within a monotonous nomenclature the living spirit of anatomy will incessantly chafe at its bonds. Not reluctant uniformity but real unanimity is the goal, and this can be attained only by the guidance of principles so definite that they will in every case unerringly lead either to the willing rejection of one term or to the willing retention of both.

Duplicate Terms.

Advocates of the B.N.A. insist upon what Professor Barker gives as one of its principles—namely, that "each part shall have only one name." Such a principle must have originated from a misconception of the functions of a nomenclature. In actual description duplicate terms, far from confusing, often throw valuable light upon a subject, and it is a mistake to suppose that they must be rigidly excluded from an international terminology which after all is scarcely a romance to be read through at a sitting. In the first place, *every structure should have as simple and natural a name as possible, but where this is long or cumbersome a shorter and more convenient name may be added.* Thus the peritoneal fold associated with the epigastric artery should be "plica arteriæ epigastricæ," and also as in the B.N.A. "plica epigastrica." Similarly the groove which lodges the transverse sinus should be "sulcus sinus transversi" and also as in the B.N.A. "sulcus transversus." The shorthand terms, however convenient, can never displace the longer ones. Though the groove for the transverse sinus may be called the transverse groove, is not the transverse groove the groove for the transverse sinus? Secondly, *in certain cases it would for linguistic reasons be simpler and more straightforward to recognise two names for a single structure even where common usage lays and will continue to lay the emphasis entirely upon one*—e.g., "testis (orchis)," "ventriculus (gaster)," cf. B.N.A. Only in this way do numerous compound terms become intelligible—e.g., mesorchium, gastro-hepatic. In the case of the tongue, "lingua (glossa)," we have the lingual artery, veins, and lymphatics, the sublingual salivary gland, the lingual, glossopharyngeal, and hypoglossal nerves, and the hyoglossus, styloglossus, and genioglossus muscles. If this principle is not to be admitted British anatomists must be prepared to resign many of their favourites. Can the terms "fibula" and "peroneal artery," for example, be defended in face of the fact that in France the corresponding terms are "la péronée" and "l'artérie péronéale"? Lastly, and most important of all, *a structure may well have more than one name when it belongs to more than one class or has more than one important relation.* The mesenteries, omenta, and ligaments so resemble each other in constitution that they may conveniently be all classed as ligaments. Certain of these ligaments in relation to the stomach may then be grouped together as omenta, and the omenta themselves grouped in relation to the stomach curvatures. In this way the present British terminology of the omenta can be reconciled with the B.N.A. and both can be retained. Again, the B.N.A. assigns to each so-called cerebral nerve a special name—e.g., "nervus trigeminus," "nervus facialis." Cunningham's Manual has therefore no authority to number these nerves "fifth cerebral nerve," "seventh cerebral nerve," and so on, however valuable this numbering may be. Indeed, the strongest argument in favour of legalising occasional duplicate names is the fact that the most virulent admirers of the B.N.A. smuggle them in whenever it suits their purpose. The more stringent the law the brisker will always be the traffic in such illicit but perfectly justifiable terms.

In the international nomenclature the details should be determined not by *ballot, as in the* B.N.A., but by the application of well-defined principles. If precision and relevance were insisted on, and if duplicate terms were admitted where they were really valuable, *many terms* now in dispute would *immediately* be either accepted or *rejected* unanimously. Where immediate unanimity proved to be impossible *synonyms* should in the meantime be inserted. Any other form of nomenclature, instead of embodying the living spirit of anatomy, would be only a sepulchre, outwardly fair with the whitewash of uniformity, but full within of *the bones of terms* from which life had long since fled.

Relation of the International Terminology to the National Language.

Until Latin becomes the international language of science, anatomists will continue to speak and write each in his mother tongue. What, then, should be the relation of the international terminology to the national language? The greatest confusion prevails in present practice, for though all are agreed that the international terminology should be employed at least as a code, some apparently wish to introduce it into, others to exclude it from, the body of the text. It is important, therefore, to have the guidance of definite principles. 1. Since the scientific literature and teaching of each nation are primarily for national use, *national terms may be employed provided always that these are clear and precise in themselves, and that they do not render the transition to the international terminology obscure or difficult.* It would detract seriously from the value of an international nomenclature if in English text-books terms such as "body, head, neck, limb, arm, forearm, hand, eye, ear, nose, kidney, stomach, heart, lung," and so on, were to be replaced by "corpus, caput, collum, extremitas, brachium, antibrachium, manus, oculus, auris, nasus, ren, ventriculus, cor, pulmo," &c. Many of the general terms which occur in the B.N.A. and which may accordingly be regarded as necessary for an international nomenclature are already current in the English language, some in Latin form—e.g., "area, isthmus, nucleus, stratum"—but the majority in a form more or less Anglicised—e.g., "muscle, nerve, process, fibre, membrane, column, space, vestibule." 2. *Where the international terms have no suitable national equivalents they may be introduced into the national nomenclature either in a nationalised form*—e.g., "commissure, decussation, clavicle, tubercle, prostate"—*or in the original "Latin"*—e.g., "perichondrium, ependyma, canaliculus, fornix, crus, stria, scapula, omentum, corona, trabecula, foramen." Professor Barker gives at least one English "synonym" for each term in the B.N.A., among them being "Berry, little head of the spoke, small piece of flesh, large hole, thread, ditch, skein, seam, round swelling, little beam, crevice, shaggy hair, whirlpool." Such synonyms are *tempting*, but one is duly warned that "in many instances it would be unwise to use the English synonym given."

The relation of the international terminology to the national languages may well be regulated by principles such as have been given above. These principles are applicable to all terms, whether Latin or Greek, simple or complex. They allow the utmost freedom in the choice of national terms, for in every case the international term may be employed unchanged, it may be nationalised in form, or it may be replaced by previously existing national equivalents. One may, for example, speak of the fasciculus longitudinalis, or the longitudinal fascicle, or the longitudinal bundle, or, again, of the extremitas sternalis claviculæ, or the sternal extremity or sternal end of the clavicle. No national term will be lawful which is *not* the precise equivalent of the international, but not every lawful equivalent will be expedient. The terms actually chosen will depend on many circumstances, and nothing will test the good sense of the individual anatomist more than the use which he makes of the international terminology. However fastidious he may be he will have little cause for *complaint.* He may delight in the long "head" of the triceps and the "caput" cæcum coli, in the "neck" of the femur and the "cervix" uteri, in the "body" of the sphenoid and the "corpus" callosum, in the "tail" of the pancreas and the "cauda" equina. He will trip lightly from the "back" to the "dorsum" sellæ, from the "arm" to the "brachium" conjunctivum, from the "leg" to the "crus" of the diaphragm, from the *"foot" to the* "pes" hippocampi, from the "ear" to the "auricle" of the heart, from the "stomach" to the "ventricle" of the brain, from the "hammer" to the tibial "malleolus," from the "fibula" to the "peroneal" muscles, from the facial "canal" to the "canaliculus" of the cochlea. The sphenoid may spread its great "wings," and the cerebellum display its "alæ." He will not fear the "cornua" of the hyoid, neither will he flee from the "horns" of the ventricle.

Conclusion.

This paper deals in a very cursory and tentative manner with some of the difficulties in the way of an international terminology, but *it will have* accomplished its object *if only it succeeds in* placing the B.N.A. in its proper perspective. Though the B.N.A. has been *long neglected* in Britain, indifference to international nomenclature is in these days the hall-mark of the indifferent anatomist. Much more creditable is the active hostility which prevails in so many quarters. A recent discussion in the Anatomical Society gave rise to a striking display of *deep-rooted* and apparently ineradicable antagonism not *untinged* with scorn. It is indeed tempting *to throw stones* at the B.N.A., but its opponents ought *first to see* to their own house. In 1895 the B.N.A., with admirable simplicity and precision, termed the space within the septum pellucidum of the brain "*cavum* septi pellucidi," yet to this day in Britain the space is *often spoken* of as "the fifth ventricle," partly doubtless because it *is not a* ventricle, partly perhaps because if it were it could not possibly be the fifth. If there is such difficulty *in* replacing in Britain so inaccurate and misleading a term as "fifth ventricle" by one so simple, *descriptive*, and accurate as "cavity of the *pellucid septum*," would it not appear a superhuman *task to* induce anatomists throughout the world *to accept* a whole nomenclature? But however much the B.N.A. *may* have suffered from *indifference* and from active hostility *it has far* more to fear from blind admiration and undiscerning praise. Some anatomists in

America and in Britain appear to have persuaded themselves that they have adopted and are consistently employing the B.N.A. A single example will show on what uncertain ground they stand. The B.N.A. contains the terms, "Cingulum extremitatis inferioris, os coxæ, os ilii, os ischii, os pubis," for which Professor Barker gives the equivalents, "Pelvic girdle, hip bone, ilium or flank bone, ischium or bone of the hip, pubic bone." It is clever jugglery to swallow "cingulum extremitatis inferioris," and then to reproduce it as "the pelvic girdle." The "os ilium," too, is the bone *of the ilia* or the iliac bone, the "os ischii" the bone *of the ischium* or the ischial bone, and the "os pubis" the bone *of the pubes* or the pubic bone. On what authority, then, does Professor Barker employ the terms "ilium" and "ischium," or Cunningham's Manual and Text-book the terms "ilium," "ischium," and "pubis," or the Companion to Manuals the terms "os ilium," "os ischium," "os pubes"? Those who are inspired by the sublime ideal of a "correct Latin" nomenclature should strangle such monsters at the birth. "Ilium," "ischium," and "pubis" are extremely convenient shorthand terms and ought to be officially adopted, but they cannot consistently be employed by any follower of the B.N.A., who will admit no duplicate terms, and who is either unwilling or unable to recognise that these coins from the anatomical mint are not current in the realm of "correct Latin."

To maintain that the B.N.A. is perfect or that even if imperfect it should at once be adopted to the exclusion of the present British or any other terminology can only alienate sympathy. Though the B.N.A. embodies all the enthusiasm and learning of a bygone generation of German-speaking anatomists its authors were under no delusion as to its real worth. As Professor Barker says, they realised that it was wiser "not to make the undertaking too wide at the beginning, to try rather to form a list of terms which should in the first place be acceptable to German-speaking anatomists, and later on to attempt to gain the coöperation of anatomists who speak other languages." Unwise admirers of the B.N.A. are clamouring for its immediate universal adoption *in toto*, but it is more in accordance with the genius and foresight of its authors that anatomists of every tongue should now "coöperate" in producing a nomenclature at once more precise, more complete, and more truly international. Should such a nomenclature be obtained it will be necessary for all anatomists whole-heartedly to abide by it, both in principle and in detail. No one should be allowed to play fast and loose with it after the present manner of the advocates of the B.N.A. Should the time not be ripe for an international nomenclature based upon the B.N.A., British anatomists ought at least to revise the terms at present in use throughout Great Britain and Ireland, and to evolve a national system as far as possible in harmony with the Basle terminology.

LITERARY INTELLIGENCE.—In response to many applications for information as to "How to Start a Day Nursery" the National Society of Day Nurseries is about to issue "A Handbook on Work in the Public Day Nursery," which will include the annual report of the society, price 1s. The information is gathered from 65 affiliated day nurseries scattered throughout London and the United Kingdom. Copies may be obtained from the secretary, 4, Sydney-terrace, Fulham-road, S.W.

ELEMENTARY TRAINING OF CHILDREN

TO REMOVE MENTAL FAULTS AND LESSEN MENTAL DEFICIENCY.

BY FRANCIS WARNER, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING PHYSICIAN TO THE LONDON HOSPITAL AND LECTURER ON THE NEUROSES AND PSYCHOSES OF CHILDREN.

WHEN a child is brought to the doctor for examination and advice on account of some mental faults, backwardness, or deficiency, a diagnosis should be made upon which a scientific prognosis can be given, and a line of treatment recommended. At the same time such concomitants as naso-pharyngeal obstructions, deafness, errors of refraction, defect of the heart, and other physical defects, should be eliminated as possible causes of brain inaptitude. It is also desirable before giving an opinion to ascertain as much as possible of the child's surroundings, habits, and previous training. Our aim in all these cases should be to train each normal character of brain action, stage by stage, on a definite plan according to the age of the child and his increasing brain power, while implanting in the teacher's mind a clear idea of their useful employment for social and mental life in the future. The work wanted from the teacher is often difficult and laborious, but interesting, and needs our guidance at each stage with directions what to observe and what to do, with assistance in overcoming individual difficulties, and using each degree of brain power gained in order to make it useful.

There are many points in elementary training that may be used in all cases, whether for the treatment of mental faults in a good brain or in a case of mental deficiency: but while in the former beneficial results may soon be achieved, in the latter long-continued perseverance is necessary to produce visible results. Among mental faults that may occur in well-made brains (psychoses) examples are as follows: "inaccuracy" in reading and in arithmetic from imperfect training in eye movements; "forgetfulness" from imperfect sensory impressions by sight or hearing: "mental confusion," specially on auditory stimulus, so that the child is *excited* by a sharp question or command, and better controlled by teacher's look or gesture, as is often the case with stammerers; forgetfulness may also be due to fatigue. Dulness in response may be due to partial deafness. Laziness in mental work is in some cases remedied by active drill and manual occupations.

Methods of Training.

I do not here deal with these faults in detail, but pass on to methods in training useful in the treatment of such conditions from which selection may be made suitable to the individual case, while all must be perseveringly employed for the defective child. When we have a well-made brain partially out of working order, the special training may soon effect good results and be replaced by ordinary educational teaching; but in cases of congenital defect the special training must be carried on daily till better aptitude is built up in the brain, while the whole day is occupied under control. Defective children who have previously been left unoccupied or "at play" without any systematic endeavour to control their brain power by a healthy mind are almost always improved by establishing organised methods of dealing with them, however feeble their powers may be at first. Systematic training of the defective child may commence by gradually accustoming him to the erect position of the head, which is favourable for movements of the tongue, lessens dribbling, enables him to see around, and gets him ready for articulation. Vocalisation in any degree should be encouraged. The child should be trained to move his eyes; get his eyes to follow without head movement an object held by the teacher, or a lighted match moved vertically and horizontally slowly and equally. This is followed after practice by seeing accurately what is shown in observing teacher's mouth when teaching speech and in imitating her movements; it is the first training in "attention," and will be used later in counting at sight. Exercises in imitation of movements seen should be practised daily, they afford the best method of producing temporary brain coördination when words are not understood. The child will at first probably only repeat the teacher's movements of the arm at the shoulder and elbow; when more advanced, movements of individual digits, one at a time, may be imitated with increasing accuracy, and still later in combinations of two or three fingers at a time. A straight balance of the hand, with all digits in the same plane, should be taught to children more advanced. In these exercises of coördination the pupil sees the teacher's movements, and the nerve centres in his brain, which correspond respectively to those in action in the teacher, are stimulated to activity in the same order and relations in time, thus giving us the power of coördinating his brain as may be desirable. Such training is very useful in overcoming neuroses, and lessening the uncontrolled spreading extra-movements which often accompany stammering. The movements of fingers used in writing, in catching a ball, or using a spoon, as well as pronation and supination, can thus be taught.

Exercises to Produce Muscular Tension.

When any action under control can be obtained means should be taken to produce muscular tension as well as movement; any controlled action produces some brain coördination, but when the action overcomes a resistance the muscular tension resulting not only promotes muscular growth, but also, I believe, sends a useful stimulus from the muscle to the brain, tending to increase its healthy growth. The muscles of the legs are usually better developed in normal children than those of the arms, owing to the tension thrown upon them by the weight of the body; defective children are usually subnormal in weight, so that less muscular work is necessarily spent in walking; they often take long walks without much muscular work done or fatigue. If the child carries weights in his hands, or a satchel on his back with, say, 3 lb. in it, more muscular work is done in walking a mile; weights of 1–3 lb. may be carried round the room, and heavy bricks or logs substituted for toys in the nursery. Children are often lazy, real work does them good, it helps to improve digestion, removes constipation, and prepares the pupil for the gymnasium and manual work. When an exercise is fairly well performed it should be practised with a resistance to the movement to produce muscular tension. Thus, when movements of the head are made to command, the same effort to action while the teacher holds the head with her hands brings the muscles into strong play; exercises for the muscles of the jaw and those of the hands I described recently. Accustoming the child to look at near and at distant objects improves the muscular apparatus of accommodation, with development of the sense of distance. The sense of muscular tension is very useful in producing mental aptitude in making comparisons, appreciation of the use of numbers, and subsequently the value of coins by their relative weights, also an understanding of arithmetical addition and subtraction with other employments of figures. Thus, before the pupil has ability to count or express what he feels he may be trained by muscle sense; let him hold in his hand weights of ½ oz., 1 oz., 1½ oz., 2 oz. in succession and feel the weight without the size; after practice he may be able to express the numbers corresponding to each weight he has felt in increasing series and understand the relations of numbers.

Training in these and other motor exercises after some months of daily practice leads to a great increase of mental ability and controllability in a defective child, with better sleep and health. The increasing mental aptitude should be used in making comparisons and expressing them while trying to educate the pupil in observation. In many other ways which there is not space for me to describe here we can make sensory impressions without words to be called into reactivity later and used in making observations and inference as experience is gained stage by stage. Verbal control, the use of words, and some understanding are usually evolved sooner than self-helpfulness. Well-planned educational training on the lines indicated thus briefly does much to evolve mental faculty in the brain and remove mental faults.

London Hospital.

MEDICINE AND THE LAW.

The Court of Criminal Appeal and Verdicts of Insanity.

AN important judgment was delivered recently in the House of Lords by Lord Reading upon the question whether a person tried upon indictment for a crime and found by a jury to be "Guilty but insane" can appeal against that verdict to the Court of Criminal Appeal. In the case before their lordships a man named Felstead had been indicted for feloniously and maliciously wounding his wife, and had been found guilty but insane when he committed the act proved to have been done by him. He had been ordered in the ordinary way to be detained during His Majesty's pleasure, and presumably he appealed because, being able to appreciate his position, he would have preferred a fixed sentence of imprisonment to detention for an indefinite period in a criminal lunatic asylum. The Court of Criminal Appeal held that it had no jurisdiction to entertain the appeal, because the Criminal Appeal Act, 1907, only entitles it to hear appeals from persons "convicted on indictment," and because it considered that a person had not been so convicted against whom the special verdict of "Guilty but insane," under the Trial of Lunatics Act, 1883, had been recorded. The House of Lords agreed with this decision, Lord Reading tracing in an exhaustive judgment the history of the law with regard to the trial of insane persons. The law, to put it briefly, has developed on the following lines: In earliest times a prisoner found to have been insane when he did an otherwise criminal act was not acquitted, but was the subject of a special verdict giving him the right to pardon. At a later period, in similar circumstances, he could either be found not guilty or could receive judgment of the court acquitting him after a verdict had been returned that he was *non compos mentis*. As this procedure might involve the release of a dangerous lunatic, an Act was passed in 1800 "for the safe custody of insane persons charged with offences," so that the special finding of the jury at that time amounted clearly to an "acquittal on account of insanity," while the new Act empowered the court to order the accused to be detained in safe custody. Later still, in 1883, the Act now in force was passed, which does not otherwise change the law, but orders that a jury, if satisfied that the person did the act but was insane when he did it, must find a verdict to that effect. Lord Reading, in addition to tracing the law directly affecting the insane, further referred to the necessity for finding "malice" and a "felonious" wounding as essential to "conviction" in the case before the House, and came to the conclusion—which, it will be seen, was a logical one and strictly consistent with the historical development of the law—that the special verdict referred to is not a conviction upon indictment, and consequently is not one which the Court of Criminal Appeal can review. The question of the treatment of insanity by the law is a difficult one, and one which has led to considerable argument and difference of opinion upon various occasions. It is evident, moreover, that its present condition is not altogether satisfactory, as in the case referred to above, if the Court of Appeal had held that it had jurisdiction, and further that the verdict of the jury was wrong as to the insanity of the accused, there would have been no verdict against him upon which he could be punished.

Two Decisions under the Workmen's Compensation Act.

Two recent decisions under the Workmen's Compensation Act may be briefly referred to, not so much on account of any medical interest attaching to them, as on account of their showing the wide scope of the Act and the manner in which responsibility attaches to employers where death in and arising out of employment takes place. In the first case the application was on behalf of Thomas Lloyd, a posthumous illegitimate child alleged by the mother to be the son of Whittall, a workman killed by an accident. The mother further stated that Whittall had promised to marry her when she told him she was pregnant. It was held by the House of Lords, reversing the decision of the Court of Appeal, that her evidence as to what the father said was admissible to prove the child a dependent. The case may be noted as one of a class in which a statement made to a medical man attending a person dying of accidental injuries might become of importance in establishing the claim of a survivor. The second case was that of John Kelly, the young Irish schoolmaster who some little time ago was beaten to death by a number of lads in an industrial school at Trim. The mother of the deceased claimed compensation as a dependent, and the Meath county court judge held that the occurrence was an accident arising out of and in the course of the employment of the deceased within the meaning of the Act. It was contended on the other side that the result of a crime deliberately perpetrated by others could not be an accident. The Court of Appeal in Ireland was of opinion that the county court judge was right, and the House of Lords has now upheld this decision, but by a majority of one only, Lord Dunedin being strongly of the other opinion and having the support of Lord Atkinson and Lord Parkes. The Lord Chancellor, Lord Loreburn, Lord Shaw, and Lord Reading held that the appeal should be dismissed. The importance of the case to those serving in employments in which they may be exposed to personal violence is obvious.

PUBLIC HEALTH OF LONDON IN 1912.

BY resolution of the London County Council, which took effect at the beginning of 1912, the duties of medical officer of health were combined with those of education medical officer, the Council having decided that the whole of the school medical work, including the inspection and treatment of children, should be placed under the direction of the county medical officer of health. Accordingly, the complete reorganisation of the central health department has been decided upon, a large number of administrative changes, to which reference will presently be made, having been already accomplished. We have received Vol. III. of the Council's recently issued annual report, which contains the report of the county medical officer of health and school medical officer for the year 1912.[1] Although the section on vital statistics in the annual report for 1911 had been contributed by Dr. W. H. Hamer, the present is his first complete report as county medical officer of health and education.

Having carefully read this volume we regard it as a valuable extension of the series of reports for which State medicine is indebted to Dr. Hamer's eminent predecessor, Sir Shirley F. Murphy. As the work abounds with matter of supreme importance to all who are interested in sanitary progress, and especially to students of preventive medicine, we regret that limitations of space prevent the inclusion, in the present review, of more than a bare outline of its contents. But we trust that as the volume has been placed on sale at a remarkably low price, its perusal by the majority of our readers will be ensured.

The subject matter of the report is arranged thus: Part I. deals with vital statistics and sanitary administration, and Part II. is devoted to elementary education in its medical aspects.

PART I.—(A) VITAL STATISTICS.

The recent movement of the London population is remarkable, inasmuch as, for the first time on record, it has experienced a decrease in the course of the last intercensal period. During the 100 years ending with 1901 there had been, in round numbers, a growth from 959,000 to 4½ millions, although since 1881 the rate of increase has declined from 17·4 to 7·3 per cent. Concurrently with a decline of 0·3 per cent. in the population of the London County since 1901 the "outer ring" has shown an increase amounting to 33·5 per cent., the rate of increase in the whole of England and Wales having averaged 10·9 per cent.

Still Falling Birth-rate.

The steady decline in the London birth-rate recorded in previous reports has continued, and the rate for 1912 (24·5 per 1000) is the lowest recorded in London since the institution of civil registration. The causes of this continuous fall in the birth-rate have long been, and still are, the subject of serious controversy. In the present report Dr. Hamer discusses the question at considerable length, but the grounds on which his conclusions rest do not readily admit of summary. It must suffice to quote his provisional opinion that "there is much to be said in favour of the view that the fall is in the main a natural one, and represents the adjustment brought about by the ordinary laws which affect movement and growth of populations." In comparing the birth-rate of the metropolis with that of other great English towns Dr.

---

[1] Published by P. S. King and Sons. Folio pp. 235 + lxxiv. Price 2s. 6d.

Hamer remarks that "the London figures alone are fully corrected by the exclusion of births within the county to mothers not usually resident in London." He ventures the opinion that if the births in other towns were similarly corrected considerable modifications of the published birth-rates might result. The decrease in birth-rate prevailing in London is shared by all the foreign capitals; indeed, the London birth-rate compares not unfavourably with that of the largest among them. But inasmuch as there exists much difference in practice as to the allocation and registration of births in foreign towns, the rates locally recorded must be regarded as only approximately comparable.

London-Life-table 1901–10.

For the purpose of comparing the health conditions of different communities the use of uncorrected or crude death-rates is generally condemned as fallacious by modern sanitarians, who recognise in the life-table method a trustworthy expedient for eliminating errors due to differences in the age constitution of the populations compared. The first extended life-table for London was published by Sir Shirley Murphy in his report for the year 1901, and was based on the mortality experience of 1891–1900. The present life-table is the second of the series, and its value is enhanced by the fact that the methods of construction of both tables being the same their results are strictly comparable. This table, which is illustrated with appropriate diagrams, may usefully be preserved as exemplifying a simple but effective method of construction, the details of which were fully described in the report above referred to. Compared with its predecessors, the present life-table indicates that the expectation of life has increased, in the case of males by 5·76 years, and in the case of females by 6·08 years. From data in the text it would appear that in recent years changes, greater than any that can be accounted for by causes ordinarily assigned, have taken place in the constitution of the London population. These changes are believed to be due mainly to the marked outward movement of the inhabitants over the county boundary, and, as far as the earlier ages are concerned, to the diminution in the birth-rate since the "eighties."

London Mortality in 1912.

In the year under review both the death-rate from all causes (13·6 per 1000 living) and the infantile mortality (91 per 1000 births) were the lowest hitherto recorded. In the annual report for 1901 the life-table method was indicated as the best known means of estimating the effect on a community of fluctuations in mortality. In order to apply this method the mean future lifetime of males and females at definite age-groups must first be obtained from a life-table. This has been done in the present instance, and in an instructive table the number of deaths occurring in the year 1912 is compared with the number that would have occurred had the death-rate prevailing in the previous decennium been maintained throughout that year. The number of lives gained in the latter period is also shown, and the figures given express this gain in terms of "life capital"—this being obtained by applying the mean future lifetime figures to the number of lives gained at each age-group. From this table it appears that during the year 1912, as compared with the decennium 1901–10, there has been a saving of not fewer than 10,065 lives, representing a gain to the community of 487,455 years of "life capital."

Infantile Mortality.

The profound and growing interest now concentrated on the subject of infant life protection is due to a general recognition of the teaching of vital statistics that much of the prevailing waste of infant life is preventable. For the last seven years medical officers of health have been required to furnish to the Local Government Board returns of mortality in successive weeks and months of the first year after birth. In London effective use is made of these returns. An instructive table appears in the present report showing the effect of social conditions on infant mortality as it obtains in five groups of London districts. The figures for 1905–11 show that in each successive trimester of the first year of life the difference of mortality in the several district groups becomes more pronounced. If, for example, the mortality at ages 9 to 12 months in the districts of "highest social condition" be taken as 100, the rate in the lowest social districts will be represented by 235.

Mortality from Specified Causes.

From the section on epidemic diseases it appears that the mortality from small-pox, measles, whooping-cough, and scarlet fever was below the quinquennial average. The incidence of the notifiable infectious diseases also showed considerable abatement. The question of enteric fever causation has always received much attention in these reports. In the year under notice no mention of exceptional prevalence of this disease has appeared in any of the district reports. In the county of London only 704 cases were notified during the year, or 318 fewer than in the preceding year. As illustrating the difficulty of diagnosis frequently experienced, it is important to notice that "the cases certified to be enteric fever and admitted to the hospitals of the Metropolitan Asylums Board, but in which the diagnosis was not subsequently confirmed, constituted 40·8 per cent. of the total cases admitted during 1912." Dr. Hamer discusses at considerable length an important report on enteric fever in South-West Germany, which appeared in 1912, and in which are given the results of a campaign against the disease undertaken by Koch. Reference is made to recent experience of the disease in South-West Germany as contrasted with that in London and in Belfast.

Pulmonary Tuberculosis—Phthisis.

From a diagram giving the death-rates from phthisis since 1851 we learn that in London there has been a marked decline in the mortality of both sexes; that its greatest incidence is upon males; and that until recent years the decline had been more manifest in females than in males. From the beginning of 1912 a complete system of notification of pulmonary tuberculosis has been in force; but the results for that year cannot be considered representative, inasmuch as many old cases were then notified for the first time. A uniform system of tabulating the notified cases is urgently needed, and in the event of its accomplishment many data of social and economic importance would in a few years be available for the guidance of sanitary authorities. From an instructive table the close relationship existing between "social condition" and phthisis mortality is conspicuous. It will there be seen that in the lowest social groups the loss of life from phthisis is more than twice that in the highest social group.

(B)—SANITARY ADMINISTRATION.

Midwives Act, 1902.

The supervision of midwives in London is entrusted by the Council to two medical inspectors, Miss E. Macrory, M.B., and Miss M. A. Pilliet, M.B. The number of midwives on the Council roll is 4985, of whom only 558 have given notice of their intention to practise. About 30,000 labours annually are attended by London midwives. In addition to routine inspection, the medical inspector pays special visits to a midwife whenever a case of septic nature or persistent high temperature occurs in her practice. In 1912 the inspectors paid 1570 such visits to midwives or institutions employing midwives, respecting 1121 of which the reports were satisfactory. About 3000 confinements occur annually in Poor-law infirmaries, most of which are conducted by midwives. Over 5000 cases are taken annually to the maternity hospitals, and some 18,000 or 20,000 women are delivered in their own homes by midwives working for maternity hospitals. Of the total births in London it is estimated that 25 per cent. are attended by midwives, excluding the cases attended in infirmaries. The rules of the Central Midwives Board provide that in certain cases a midwife must decline to attend alone, and must advise that medical aid be obtained. During the year this rule was obeyed in 3603 instances, as compared with 1113 instances in the year 1905. Assuming that 30,000 confinements were attended by midwives in 1912, it appears that medical assistance was required in 12 per cent. of the cases—viz., in 7·8 per cent. on account of the mother, and 4·2 per cent. on account of the child. During the same year 380 cases of puerperal fever were notified, of which 124, or 33 per cent., terminated fatally. It is the duty of a midwife to advise medical help whenever inflammation of the eyes occurs in an infant. Thereupon a medical inspector visits the child to ascertain whether the child has received medical aid either at home or in a hospital. In 1912 the Council's inspectors visited the 383 children reported as requiring medical attention. 298 of these were reported cured; in 4 cases there was impairment of vision; the remaining children either died during treatment or were lost sight of.

Food Inspection.

The milk-supply of London continues to receive careful supervision by the Council's officers. The registers of cowhouses, dairies, and milkshops are frequently revised, and the sanitary condition of these places is kept under observation. The cows in the London cowsheds are periodically examined by the veterinary inspector with a view of detecting animals affected with tuberculosis. In the course of the year six inspections of all the cows in the London cowsheds were made, with the result that 22 cows were slaughtered because of the existence of tuberculosis of the udder. The carcasses were destroyed and statutory compensation was paid to the owners. Under Part 4 of their General Powers Act the Council is authorised to deal with tuberculous milk. Under these powers the inspectors take samples from churns of milk consigned from the country to the London railway termini, and these are submitted for examination to the Lister Institute. Whenever the examination proves the existence of tubercle bacilli in the milk a clinical examination of the cows at the dairy farm concerned is made by a veterinary inspector, and cows found to have tuberculous udders are certified to be dealt with under the Dairy and Cowsheds Order. During the year 2991 samples of milk were examined, of which 8·4 per cent. were returned as tuberculous, the proportion thus returned in the preceding year having been 10·4 per cent.

Cleansing of Persons Act.

Particular attention has been paid during the year to the administration of the Cleansing of Persons Act of 1897, and of the powers conferred by the cleansing sections of the General Powers Acts. Associated with this work is the inquiry into the seasonal prevalence of flies and of particular kinds of vermin, and the comparison of this prevalence with the incidence of certain contagious diseases. This subject was dealt with in detail in the report for 1909, and was again referred to in the report for 1911, when a diagram was inserted showing the relationship between prevalence of flies and diarrhœa mortality.

(*To be concluded.*)

MARCH AT HOME AND ABROAD.

At Home.

MARCH, which in this country is generally among the very driest periods of the year, proved a striking exception to the rule. Very few days (or nights) passed without more or less rain, and the sunshine was much below average. The wind nearly always came from some mild point of the compass, usually from south-west or west, with the result that frost was seldom experienced, and the temperature was generally high for the time of year. The first fortnight was, however, considerably milder than the last, and the mean temperature for the whole month worked out at between 1° and 3° above the average. At the Kew Observatory, which may be taken to represent the metropolitan area and the Home Counties, the mean maximum temperature of the afternoons was a trifle below 50°, or 1° above the normal, while the mean minimum of the nights was 37½°, also 1° above the normal. Exceptionally warm days for March were rare; on the 12th the thermometer touched 57°, but failed to rise so high again until the 31st, when it reached the genial figure of 63°. Very low maxima were equally rare; on the 9th there was no higher reading than 43°, and on the 20th the maximum was 39°, but on all the other days the figure ranged above 45°. Frost in the air occurred on only seven nights, although ground frost was naturally much more frequent. A normal March gives 13 days with rain, yielding a total of 1·59 in., but last month the number of rainy days was 27 and the aggregate fell 3·33 in. The rain was, nevertheless, seldom heavy, and the greatest amount within 24 hours was 0·[illegible] in., on the [illegible]. As many as nine days were entirely sunless, and several others afforded but an [illegible] glimpse, with the result that the total duration for the month was no more than 53 hours, against an average of [illegible] hours. [illegible] the Midlands and Western England it differed little from London in the temperature. Nottingham was [illegible] colder both during the day and night, and Bath a little warmer. Both places had rain on 23 days, the respective falls being 2·12 in. at Nottingham, 0·52 in. more than the average, and as much as 4·01 in. at Bath, an amount exceeding the normal by 2·49 in. At Buxton the mean maximum temperature was 44° and the mean minimum 34°, while the rainfall reached 5·80 in. divided between 28 days. Of the three inland places Bath was the most sunny, getting 92 hours, against 67 hours at Nottingham and 71 hours at Buxton. All the figures were much below the normal, that at Nottingham showing a deficit as great as 49 hours, or more than one and a half hours per day. The south coast, as represented by Brighton, was between 2° and 3° warmer than London both before and after sunrise, while Newquay, in the extreme south-west, was a little warmer than Brighton. Both resorts were rainy. At Brighton rain fell on 23 days and yielded a total of 4·57 in., an excess on the normal of 2·85 in.; and Newquay, with rain on 26 days, had an aggregate of 5·12 in., or 2·78 in. more than the average. Newquay was the brighter spot, recording 117 hours of sunshine, less than half an hour per day below the March normal; at Brighton the total amounted to only 104 hours, being nearly 30 hours less than the average. At Torquay the sun's record was 11 hours higher than at Newquay.

Abroad.

The western and central countries of the continent shared in the dull, wet weather, although their rain was not so frequent as in some parts of England. At Paris 21 days gave more or less rain, and the whole 31 days could give no more than 83 hours of sunshine, only five hours more than at Kew. As a rule, the rain was slight and the aggregate was no higher than 2·36 in. As is nearly always the case in March, Paris was warmer than London, its temperature being between 3° and 4° higher. Really warm days were very few. Almost all the maximum readings were some way below 60° until the 30th, when the thermometer rose to 62°, followed by 69° on the 31st. Brussels had more rain than London, the total, falling on 26 days, amounting to 4·47 in., while the mean temperature was practically the same as at Kew, both during the day and night. At Berlin the temperature was about equal to that in the English midlands, although frost was more rare. From the 4th to the 17th rain fell almost daily and altogether 21 days were rainy, giving a total of 3·03 in. On the Riviera a few days were very wet, but most of the month proved fine and bright, and on many days the temperature rose to 60° and above. At Nice the mean maximum was as high as 58°. The mean minimum, however, was a little lower than at Jersey and the Scilly Isles, the figure being 42°. At Biarritz the weather was very wet and often very rough, gales from the westward occurring frequently. On as many as 23 days a measurable quantity of rain was experienced, and the aggregate was as large as 6·76 in. Day after day was either very cloudy or entirely overcast, but with the wind from the south-west or west the temperature was never low, and the mean for the month was about the same as at Nice. As at Paris and in this country a great rise of temperature occurred at the end of the month, the 31st bringing a maximum as high as 77°. Over the greater part of Italy the weather was warmer than on the Riviera, although rain was more common. Some sharp falls were general early in the month, and after the 15th very few days were dry. At Rome rain fell on 13 days, with a total of 2·77 in. The mean maximum temperature was fairly high, exceeding that at Nice by 3°, and a similar difference was shown by the minimum thermometer. Down at Madeira the month was almost continuously fine. Only three days brought rain, while the temperature, very equable, had a mean of 64° during the afternoon and 54° at night. The highest reading recorded was 70° on the 16th, and the lowest 55° on the 5th and 9th.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns 9011 births and 5550 deaths were registered during the week ended Saturday, April 4th. The annual rate of mortality in these towns, which had been 15·4, 15·2, and 15·5 per 1000 in the three preceding weeks, declined to 15·2 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 15·4, against 16·1 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 7·7 in Enfield, 8·1 in Ealing, 8·4 in Eastbourne, and 8·7 in Wimbledon and in Dewsbury, to 22·7 in Great Yarmouth and in Swansea, 23·3 in St. Helens, 23·9 in Plymouth, 27·6 in Rochdale, and 28·1 in Dudley.

The 5630 deaths from all causes were 111 fewer than the number in the previous week, and included 484 which were referred to the principal epidemic diseases, against numbers steadily increasing from 397 to 488 in the six preceding weeks. Of these 484 deaths, 172 resulted from whooping-cough, 137 from measles, 77 from infantile diarrhœal diseases, 51 from diphtheria, 35 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·4, against 1·3 and 1·4 per 1000 in the two preceding weeks. The deaths attributed to whooping-cough, which had steadily increased from 110 to 162 in the six preceding weeks, further rose to 172, and caused the highest annual death-rates of 1·6 in West Ham and in Middlesbrough, 1·7 in Exeter and in Rochdale, 1·8 in Great Yarmouth and in Darlington, and 2·0 in Dudley. The deaths referred to measles, which had been 113, 107, and 140 in the three preceding weeks, fell to 137; the highest death-rates from this disease were 1·6 in Rhondda, 1·7 in Sheffield, 1·8 in Leicester and in Stockton-on-Tees, 1·9 in West Ham, 2·0 in Dudley and in Nottingham, and 2·2 in Rochdale. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 74, 73, and 65 in the three preceding weeks, rose to 77, and included 16 in London, 8 in Liverpool, 7 in Birmingham, 6 in Manchester, 3 in Burnley, and 3 in Merthyr Tydfil. The deaths attributed to diphtheria, which had been 67, 51, and 73 in the three preceding weeks, declined to 51, of which 19 occurred in London and its suburban districts, 6 in Birmingham, 3 in Leeds, and 3 in Sheffield. The deaths referred to scarlet fever, which had been 31, 37, and 33 in the three preceding weeks, were 35, and included 8 in Birmingham, 7 in London, 3 in Manchester, and 2 each in Walthamstow, Sheffield, and Newcastle-on-Tyne. The fatal cases of enteric fever, which had been 13, 21, and 15 in the three preceding weeks, further declined to 12, of which 3 were recorded in London.

The number of scarlet fever patients in the London Fever and the Metropolitan Asylums Hospitals, which had steadily decreased from 3599 to 3143 in the nine preceding weeks, rose to 3183 in the week under notice; 400 new cases were admitted during the week, against 320, 319, and 347 in the three preceding weeks. These hospitals also contained on Saturday, April 4th, 1316 cases of diphtheria, 357 of whooping-cough, 134 of measles, and 67 of enteric fever, but not one of small-pox. The 1344 deaths from all causes in London were 89 fewer than the number in the previous week, and were equal to an annual death-rate of 15·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 223, 250, and 291 in the three preceding weeks, declined to 280, and were 98 below the number recorded in the corresponding week of last year.

Of the 5630 deaths from all causes in the 97 towns, 191 were attributed to different forms of violence, and 460 were the subject of coroners' inquests. The causes of 51, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, Hull, and in 50 other smaller towns. Of the 51 uncertified causes of death, 9 were registered in Birmingham, 7 in Liverpool, 3 each in Preston, Gateshead, and Tynemouth, and 2 each in Portsmouth, Dudley, Warrington, and Darlington.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns 1240 births and 819 deaths were registered during the week ended Saturday, April 4th. The annual rate of mortality in these towns, which had been 17·9, 16·6, and 16·5 per 1000 in the three preceding weeks, rose to 18·6 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these Scotch towns averaged 18·2, against 16·4 per 1000 in the 97 large English towns. Among the several towns the death-rate in the week under review ranged from 7·6 in Kirkcaldy, 8·2 in Clydebank, and 13·8 in Perth and in Motherwell, to 20·9 in Aberdeen, 23·5 in Kilmarnock, and 25·4 in Greenock.

The 819 deaths from all causes were 93 in excess of the number in the previous week, and included 81 which were referred to the principal epidemic diseases, against 66 and 78 in the two preceding weeks. Of these 81 deaths, 37 resulted from measles, 15 from whooping-cough, 14 from infantile diarrhœal diseases, 9 from diphtheria, 4 from scarlet fever, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·8, against 1·4 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 34, 38, and 34 in the three preceding weeks, rose to 37, of which 21 occurred in Glasgow, 5 in Edinburgh, 3 in Ayr, and 2 each in Paisley, Coatbridge, and Motherwell. The deaths referred to whooping-cough, which had been 8, 10, and 11 in the three preceding weeks, further rose to 15, and included 8 in Glasgow and 4 in Coatbridge. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 10, 5, and 14 in the three preceding weeks, were again 14 in the week under notice; of this number 5 occurred in Dundee, 3 in Glasgow, and 3 in Aberdeen. The deaths attributed to diphtheria, which had been 14, 6, and 9 in the three preceding weeks, were again 9, of which 3 were recorded in Glasgow. The 4 deaths referred to scarlet fever, which were all registered in Glasgow, were 5 below the average in the earlier weeks of the quarter. The 2 fatal cases of enteric fever and also 1 of typhus occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 137, 117, and 111 in the three preceding weeks, rose to 166 in the week under notice; 33 deaths resulted from various forms of violence, against 22 and 31 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland 747 births and 502 deaths were registered during the week ended Saturday, April 4th. The annual rate of mortality in these towns, which had increased from 19·2 to 22·8 per 1000 in the four preceding weeks, fell to 21·7 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 21·5 per 1000; in the 97 large English towns the corresponding rate did not exceed 16·4, while in the 16 Scotch towns it was equal to 18·2 per 1000. The annual death-rate for the week under review was equal to 26·1 in Dublin (against 15·5 in London and 19·0 in Glasgow), 17·8 in Belfast, 21·1 in Cork, 14·0 in Londonderry, 17·6 in Limerick, and 35·1 in Waterford, while in the 21 smaller towns the mean death-rate was equal to 21·4 per 1000.

The 502 deaths from all causes were 24 fewer than the number in the previous week, and included 48 which were referred to the principal epidemic diseases, against numbers increasing from 33 to 67 in the four preceding weeks. Of these 48 deaths, 26 resulted from measles, 10 from whooping-cough, 6 from infantile diarrhœal diseases, 3 from scarlet fever, and 3 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 2·1 per 1000, against corresponding rates of 1·4 and 1·8 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had increased from 4 to 34 in the four preceding weeks, declined to 26, of which 22 occurred in Dublin. The deaths referred to whooping-cough, which had been 4, 11, and 12 in the three preceding weeks, fell to 10, and comprised 3 in Dublin, 3 in Belfast, 3 in Cork, and 1 in Tralee. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 14, 9, and 8 in the three preceding weeks, further declined to 6, but showed no excess in any of the towns. The 3 deaths attributed to scarlet fever, of which 2 occurred in Belfast, were 4 below the average in the earlier weeks of the quarter. Of the 3 deaths referred to diphtheria, which coincided with the average in the earlier weeks, 2 were registered in Belfast and 1 in Cork.

The deaths referred to diseases of the respiratory system, which had increased from 97 to 113 in the four preceding weeks, further rose to 118 in the week under notice. Of the 502 deaths from all causes, 158, or 31 per cent., occurred in public institutions and 8 resulted from various forms of violence. The causes of 23, or 4·6 per cent., of the total deaths were not certified either by a registered medical practititioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes of death did not exceed 0·9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeon: H. S. Hall to the *Challenger* and for group of Third Fleet ships. Staff-Surgeons: J. Bourlas to the *Triumph*, additional for Hong-Kong Hospital; J. E. Johnston to the *Adamant*; and D. D. Turner to be lent to the *Hearty*, temporary.

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned has been appointed a Surgeon: Armin Gascoigne Vavasour Elder (dated April 8th, 1914).

ROYAL ARMY MEDICAL CORPS.

Surgeon-General W. Babtie, V.C., C.B., C.M.G., has been appointed Director of Medical Services to His Majesty's Forces in India, vice Surgeon-General Sir A. T. Sloggett, C.B., C.M.G., transferred to the Home Establishment.

Colonel W. W. Pike, D.S.O., has been selected for appointment as Assistant Director of Medical Services to the

Abbottabad and Sialkot Brigade, vice Colonel R. Kirkpatrick, C.M.G. Colonel W. M. Russell has taken up duty on the Headquarters Staff at Malta as Deputy Director of Medical Services.

Lieutenant-Colonel J. C. Connor has been selected for appointment as Deputy Assistant Director of Medical Services to the Irish Command Headquarter Staff. Lieutenant-Colonel B. H. Scott has been appointed for duty in the London recruiting area. Lieutenant-Colonel G. W. Tate has been appointed Senior Medical Officer to the Military Hospital at Bermuda. Lieutenant-Colonel N. Faichnie has arrived home for duty from India. Lieutenant-Colonel R. H. Penton has been appointed in charge of the Military Hospital at Ranikhet Cantonment.

Major J. H. Barbour has arrived home from India. Major E. V. Aylen has been transferred from the Military Hospital at Gharial to Rawal Pindi Cantonment. Major E. W. Slayter has been appointed to hold charge of the Military Hospital at Cahir. Major R. L. Popham and Major E. S. Clark have embarked for India. Major J. E. R. Bond has taken over charge of the Military Hospital at Naini Tal. Major R. Tilbury Brown has joined at Darjeeling. Major J. T. Johnson has been appointed Deputy Assistant Director of Medical Services, Sanitary Branch, to the Eighth (Lucknow) Division. Major G. S. Crawford has been appointed to officiate as Medical Inspector of Recruits to the Irish Command Headquarters Staff. Major G. J. S. Archer has been transferred from Cosham to Dorchester. Major D. Harvey has been appointed for duty to the Royal Army Medical College, Grosvenor-road, S.W. Major A. A. Seeds has been transferred from the Military Hospital at Campbellpore to Rawal Pindi Cantonment. Major H. N. Dunn has been selected for advancement to the rank of Lieutenant-Colonel. Major H. K. Palmer has arrived home from Aden. Major W. A. S. J. Graham has been appointed Senior Medical Officer at the Military Hospital, Neemuch Cantonment. Major C. J. O'Gorman has been appointed Civil Surgeon in the Barrackpore District, vice Lieutenant-Colonel F. C. Morgan. Major W. G. Beyts has been appointed to hold charge of the Military Hospital at Roorkee Cantonment. Major M. M. Lowsley has been appointed Specialist in Midwifery and Diseases of Women and Children to the Third (Lahore) Division. Major W. W. Browne has been appointed Specialist in the Prevention of Disease to the Ahmednagar Brigade and placed in charge of the Bacteriological Research Laboratory at Headquarters. Major H. W. Grattan has been appointed Honorary Surgeon to H.E. the Viceroy and Governor-General of the East Indies.

Captain G. Ormrod has embarked for the Sierra Leone Protectorate. Captain A. Irvine-Fortescue has taken up special duty in Japan. Captain D. deC. O'Grady has been appointed to the Eastern Command. Captain C. Ryles has arrived home from India. Captain R. J. Franklin has been appointed to Solon Cantonment. Captain T. C. C. Leslie has embarked for India. Captain F. W. W. Dawson has been appointed Specialist in the Prevention of Disease to the Jullundur Brigade and placed in charge of the Bacteriological Research Laboratory at Headquarters. Captain D. G. Carmichael has been appointed to hold charge of the Military Hospital at Khanspur. Captain E. B. Lathbury has arrived home from Bareilly Cantonment. Captain K. A. C. Doig has been appointed to the staff of the Military Hospital at Meerut Cantonment. Captain A. C. Amy has taken up duty at Manchester. Captain J. H. Duguid has been appointed Specialist in Otology to the Ninth (Secunderabad) Division. Captain C. E. W. S. Fawcett has embarked for India. Captain C. B. Millar has been appointed to hold medical charge at Fort Camden, Queenstown. Captain E. C. Whitehead has taken up duty at Dinapore Cantonment. Captain C. W. Bowle has arrived home from Jubbulpore Cantonment. Captain A. M. Pennefather has been appointed to hold charge of the Military Hospital at Newport. Captain G. F. Rugg has been appointed Specialist in Advanced Operative Surgery to the First (Peshawar) Division. Captain W. K. Rennie has arrived home from Malta. Captain T. W. Browne has been transferred from Tipperary to the Military Hospital at Buttevant. Captain A. C. Elliott has been appointed to hold medical charge at Landguard Fort. Captain R. D. O'Connor has arrived home for duty from Multan Cantonment. Captain H. H. Leeson has been transferred from the Military Hospital at Alexandria to Cairo.

INDIAN MEDICAL SERVICE.

Surgeon-General Sir C. Pardey Lukis, K.C.S.I., has been appointed an Additional Member of the Legislative Council of the Governor-General of India.

[illegible] and Lieutenant-Colonel H. F. Cleveland [illegible] Honorary Surgeon to the Viceroy. Lieutenant-Colonel E. C. MacLeod has been appointed [illegible] of the Tezpur Jail. Lieutenant-Colonel A. H. Nott has been granted furlough for two years. Lieutenant-Colonel W. R. Edwards, C.M.G., has taken up duty as Chief Medical Officer to the North-West Frontier Province.

Major J. M. Woolley has been appointed for special duty under the Government of Bengal. Major R. F. Baird has been appointed to hold charge of the Lunatic Asylum at Benares. Major H. Kirkpatrick has taken up duty as Professor of Pathology at the Government Medical College, Madras.

Captain R. A. Needham has been appointed for special duty under the orders of the Director-General. The services of Captain F. B. Shettle have been placed at the disposal of the Government of Bombay. Captain J. Woods has been appointed Substantive Medical Officer to the 53rd Regiment of Sikhs. Captain R. D. Willcocks has been appointed to the Civil Medical Department of Madras Presidency. Captain H. Coddington Brown has taken up duty at the Central Research Institute, Kasauli Cantonment, on transfer from the 47th Regiment. Captain T. W. Harley has been appointed Professor of Biology at the Government Medical College, Madras, and Surgeon to the General Hospital. Captain C. G. Seymour has been appointed Specialist in the Prevention of Disease. Captain J. McC. Anderson has joined at Hoshangabad. Captain J. W. McCoy has been appointed Civil Surgeon at Cachar, Assam. Captain T. G. F. Paterson has taken up duty at Surat as Officiating Civil Surgeon. Captain G. F. I. Harkness has been appointed Officiating Resident Surgeon at St. George's Hospital Bombay. Captain C. A. Gill has been appointed to officiate in the Civil Medical Department in the Punjab. Captain A. D. Stewart has been appointed to officiate in medical charge of the Gurkha Recruiting Depôt at Gorakhpore. Captain W. D. H. Stevenson has taken up duty as Assistant to the Director of the Bombay Bacteriological Laboratory.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant George B. McCaul resigns his commission (dated April 8th, 1914).

Hubert Charles George Pedler, late Surgeon-Lieutenant, 1st Life Guards, and late Staff-Sergeant, University of London Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated March 15th, 1914).

Cadet Staff-Sergeant Robert Lister Horton, from the University of London Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated March 15th, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd South-Western Mounted Brigade Field Ambulance, Royal Army Medical Corps: Lieutenant Rupert Waterhouse, from the List of Officers attached to Units other than Medical Units, to be Lieutenant (dated Feb. 9th, 1914).

1st East Anglian Field Ambulance, Royal Army Medical Corps: Major Ernest V. Gostling to be Lieutenant-Colonel (dated April 8th, 1914).

3rd West Lancashire Field Ambulance, Royal Army Medical Corps: Major Archibald Gordon Gullan, from the 1st West Lancashire Field Ambulance, Royal Army Medical Corps, to be Lieutenant-Colonel (dated April 8th, 1914). Major Elisha H. Monks resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform dated April 8th, 1914).

For Attachment to Units other than Medical Units.—Major Charles Thomson, Retired List (late Indian Medical Service), to be Major (dated Nov. 1st, 1913). Richard Mervyn Wilson (late Surgeon-Captain, Derbyshire Yeomanry) to be Captain (dated March 1st, 1914). Alfred John Gibson (late Lieutenant, King Edward's Horse (The King's Overseas Dominions Regiment) Yeomanry), to be Lieutenant (dated March 7th, 1914).

Supernumerary for Service with the Officers Training Corps.—Captain Norman Cecil Rutherford, from the Unattached List for the Territorial Force, to be Captain, for service with the University of London Contingent, Senior Division, Officers Training Corps (dated Feb. 11th, 1913).

Attached to Units other than Medical Units.—Lieutenant Jacob F. Farrow to be Captain (dated March 6th, 1914). Captain John C. S. Burkitt to be Major (dated April 8th, 1914). Captain Henry S. Walker resigns his commission (dated April 8th, 1914).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Captain Arthur T. Sissons, from the Unattached List for the Territorial Force, to be Captain (dated April 8th, 1914).

THE ROYAL ARMY MEDICAL COLLEGE.

Lieutenant-General Sir James Grierson, K.C.B., C.V.O., C.M.G., will distribute the prizes at the Royal Army Medical College, Millbank, on Friday, May 1st, at 4 P.M. After the distribution Colonel E. M. Skinner and the officers, R.A.M.C., will be at home, and afternoon tea will be served in the officers' mess.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1069.*)

XLIII.—LONDON: ADMINISTRATIVE DIFFICULTIES AT DENMARK HILL.

MY next visit was to a successful panel doctor who lives at Denmark Hill. He did not commence by eulogising the Act, but, on the contrary, was soon quite busy describing some shortcomings. Thus, the Act had just been amended, so that men up to the age of 70 were accepted. Before, the limit was 65 years. These old men have a voucher given to them. The doctor signs the voucher, the Insurance Committee then stamps it, and sends it back to the insured person, so that it now bears the doctor's signature and the committee's stamp. All this constitutes more routine than the persons concerned quite like, but it has served to show that a considerable number of these old men who were excluded from the Act before it was amended have nevertheless been receiving medical benefits all the time, for they had somehow obtained the red tickets to which they were not entitled. Also, some insured persons have been found in possession of several red tickets. Others have called on panel doctors without any red ticket at all and no evidence to show but their insurance card. As the panel doctor on whom I called has a list of 3500 insured persons whom he attends with the aid of an assistant, he has had plenty of opportunities of dealing with irregularities of this description, and the mechanism of administration is of great importance when there are so many persons needing attendance.

Since Jan. 12th a new form replaces the old red ticket, but some of the approved societies continued during the month of February issuing forms that should not have been used after the 12th of the previous month. This naturally caused a great deal of confusion, particularly as there has been such a number of forms issued. The panel doctors began working the Act on Jan. 15th, 1913, and they had then reached the form relating to medical affairs No. 20. By the month of February, 1914, they had received form No. 50. These forms relate to transfers, to medical benefits at the Post Office, to change of doctor during the year when the signatures of both doctors are needed, &c. Then there are changes of address, and, again, when a doctor has joined the panel after most of his colleagues administrative complications arise. In Form 20 the insured had only to state the name of the Approved Society to which he belonged. This has caused an appalling amount of confusion. No one seems to have foreseen that such a declaration in no wise sufficed to trace the individual. It is very little use if John Brown or George Smith merely states that he belongs to the Oddfellows or the Foresters. But if they give their number, the name and address of the lodge to which they belong, they can be traced, and their statements verified, without the slightest difficulty or delay. In consequence of this form thousands of insured persons could not be traced back to the societies to which they belonged. My informant declared that he was now attending a considerable number of persons without knowing whether they were entitled to such attendance.

The National Insurance Practitioners' Association[1] worked very hard to put some order where so much disorder prevailed; but London stood at a special disadvantage, because the opposition to the Act was so strong that it was not possible until a few weeks ago to elect a London Medical Committee as laid down by the law. This difficulty, however, it was anticipated by supporters of the Act, would be overcome by the new enactment which had brought into existence the Panel Committees officially representing doctors on the panel. In provincial and country districts this sort of committee was not so much needed. In many parts of the country a Local Medical Committee exists and is fairly representative, but it was argued that had a Medical Committee been elected for London the panel doctors' interests would hardly have made themselves felt.

The Certificate Trouble.

Yielding to the universal feeling that simplification is absolutely necessary, the Approved Societies have now all agreed to adopt the same form of certificate. Still there is trouble. The Insurance Committee gives a book of certificates, and the latter, when signed, entitles the bearer to be put on the sick list. The panel doctor hands over one of these certificates to his patient, and he at once sends it to his society. But the next day the patient may return to his panel doctor and present his Approved Society's form which has on it a certificate exactly like the one the doctor had given him the day before. This second certificate the doctor has also to sign. The following or third day is probably that on which the agent of the Approved Society makes his round of visits, and he wants yet a third certificate for the week's continuation of the sick allowance. This apparently dates according to the agent's visits and not in accordance with the patient's illness. Thus the same statement may have to be signed three times in the course of three days. It is the small Friendly Societies that give the most trouble. The big commercial insurance companies do not usually insist on such complications in regard to the signing of certificates. To add to the confusion many societies have persisted in using up their stock of "literature" even when it was no longer appropriate. Thus insured persons present themselves and make some application only to be told that their procedure, though perfectly correct according to the old rules, is to-day no longer applicable.

Financial Aspects of Panel Practice.

In answer to some of my questions, the popular doctor to whom I have referred said that many of the 3500 insured persons for whom his assistant and himself were responsible had belonged to clubs for which he was the medical officer before the Act. These patients had not changed in any way. Their behaviour and attitude had not changed at all now that they came to him as insured patients instead of members of clubs. He felt assured that patients, whether club patients or insured persons—it did not matter who they might be—if treated courteously and sympathetically would always behave back in a similar way. The doctor should be able to get on with all sorts. A certain number of his patients, he said, showed a great readiness to declare themselves sick. But they had been trained to do this and to rely on a bottle of medicine. It would take years to teach such persons that a bottle of medicine is but a small part of the treatment. Very few of his insured patients had more than £100 a year.

---

[1] See THE LANCET, Jan. 31st, 1914, p. 346.

I have come to the conclusion from all I heard that the insured persons whose incomes range from £100 to £160 are likely to occasion a little more trouble than the poorer classes. The feeling which made people imagine it was not good form to be insured is now wearing off. Fees certainly can be obtained from persons whose income is above £100, but there was previously much trouble in getting paid and many bad debts, and many persons removed leaving no address, so that even with this section, and right up to the income-tax limit, the capitation system may be found to pay better. Two panel doctors in the Dulwich and Denmark Hill district have calculated what they made per item from patients on their panel lists. The one received 1s. 3½d. per item and the other 1s. 7d. As this included the mere signing of a certificate it was really quite as good as the 1s. 6d. or 2s. fee for consultation at the surgery and the 2s. 6d. for a visit if all the bad debts are deducted. Another panel doctor, reckoning from April to the end of December—that is, cutting off the three worst months of the year—found that he had received 2s. per item. This, while it lasts, is certainly better than private practice was at minimum fees. My first informant said that he was not anxious for an income limit, and that right up to the income-tax mark he thought practice on the capitation principle paid better.

Hospitals for the Insured.

Since the Act came into force it has been found difficult in this district to get patients into hospitals, and the creation of many State or municipal hospitals is freely spoken of as a possible solution. As it is, the Insurance Commissioners have retained beds for the reception of tuberculous patients in various hospitals. Why should not this principle be extended? But if this plan were pressed to its logical consequence, side by side with the extension of the Act to include the dependents of insured workers, the whole system governing the organisation of hospitals would have to be remoulded on an entirely different basis. If everybody is to be brought under the scope of State insurance, then it would only be logical to anticipate that the hospitals must also be brought under a scheme of State management.

Perhaps when the State is thus gradually led to provide medical aid for nine-tenths of the entire population it will better realise the importance of removing the obvious causes of preventable diseases. For though Denmark Hill is a favoured district to some extent, a very earnest protest may be entered against the awful housing conditions which many of the patients under the National Insurance Act there have to endure.

It is said that these very poor and ill-housed people are often neglected or carelessly treated by the practitioners on the panels—the statement is regularly made, among others, by those who desire to see a multiplication of medical aid institutes such as have come into being in Chesterfield, and the control of medical practice falling again into the hands of clubs managed by lay committees. Let it be granted that among the first medical men to serve on the panels were medical men whose habits and routine of practice had been learned in cheap dispensaries. They were doing the work before the Insurance Act came in force, and it was not possible that they should immediately begin to order their professional lives on a higher standard. But at Denmark Hill, as elsewhere, I gathered the impression that bad work would be found out and that the lists would limit themselves in time to the most competent workers.

(To be continued.)

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

LIVERPOOL.

Annual Meeting of the Liverpool Stanley Hospital.

THE Liverpool Stanley Hospital held its forty-seventh annual meeting in the Town-hall, Liverpool, on April 7th, under the chairmanship of the Lord Mayor, Mr. H. R. Rathbone, J.P. The chairman, in moving the adoption of the report and accounts, deplored the decrease in the annual subscriptions, and appealed for a more widespread sympathy with the work of the hospitals. The president of the hospital, Sir Percy Bates, Bart., seconded the resolution, and pointed out that the effect of the recent legislation had been to increase the work of all hospitals, which needed more and more financial support. Mr. Oswald Dobell, the honorary treasurer, submitted the balance-sheet, which showed a deficit on the year of £931, bringing the total debit balance up to £4462. Whilst this was somewhat disheartening, he had been greatly encouraged by the spontaneous response to his appeal for funds to build a much-needed nurses' home. This was now ensured, and would be a great boon to the nursing staff. Mr. W. M. King, seconded by Mr. W. Bagshaw, moved the re-election of the honorary medical staff. The Rev. Stanley Rogers, in moving the reappointment of the committee and officers, eulogised the good work which the Stanley Hospital was doing, and of which he heard so much when going about the populous and poor districts of the north end of Liverpool. The resolution was seconded by the Rev. S. Barrow and carried. The proceedings terminated with a cordial vote of thanks to the Lord Mayor.

Treatment of Tuberculosis.

The administrative officer of the Liverpool Insurance Committee (Mr. Gill Hodgson) has just issued his report on the treatment of tuberculosis. The report, which was adopted at the meeting of the committee, gave the exact number of applications for sanatorium treatment in the 18 months ending Jan. 11th as 1829, of whom 1557 were recommended for medical treatment, the pulmonary cases being 1317. Of the 1495 who had received treatment 782 were men, 338 women, 194 boys, and 181 girls. The cost of treatment had been: Sanatorium and hospital (1029), £14,487; dispensary (150), £270; domiciliary (704), £6913; total, £21,671. The results of treatment were as follows: Discharged fit for work, or if juveniles "disease arrested," 152; improved, 448; found not tuberculous, 15; unimproved, 106; worse, 6; died, 210; treatment discontinued for other than medical reasons, 37; total, 975; under treatment Jan. 11th, 520. The apparently large number of deaths was due to the fact that many advanced cases were treated where the hope of recovery was but small, the committee desiring to secure constant attention and to avoid the great risks of infection which must have been incurred by leaving these patients in their own homes.

Memorial to Dr. O. T. Williams.

A brass tablet has been placed in the chapel of the Royal Infirmary in memory of the late Dr. O. T. Williams, who was assistant physician to the hospital, and who died on Jan. 15th, 1913, in his thirty-sixth year. The tablet bears the following inscription:—

> "A true physician, an ardent student, a helpful colleague, a faithful friend."

The tablet is the gift of the medical board of the infirmary.

April 11th.

SCOTLAND.

Annual Report of the Registrar-General for Scotland.

IN the last annual report, now issued, it is stated that the birth-rate for the year is the lowest on record. The number of births registered during the year was 121,850, being 2209 fewer than in the preceding year, and equal to a birth-rate of 25·65 per 1000, or 2·73 less than the average rate of the preceding ten years. It was, however, 1·2 more than the corresponding birth-rate of England and Wales, and 2·4 more than that of Ireland. The illegitimate rate for the year was 7·55 per cent. of the total children registered, the highest since 1891. The death-rate for the year likewise showed a large decrease, being the smallest number of deaths registered in the country since 1896, and the lowest death-rate yet recorded. It is significant to note that the deaths from tuberculous disease numbered 8387, equal to 1·77 per 1000, which is the lowest rate on record. It is 130 less than the number recorded in the previous year, and 1077 less than the mean of the numbers for the preceding five years, and 1240 less than the mean of the numbers for the preceding ten years. Registered marriages numbered 31,811, equal to a rate of 6·7 per 1000, and showing a slight decrease on previous years.

University of Edinburgh: Honorary Degrees.

Among those upon whom the Senatus Academicus have resolved to confer the degree of LL.D. *honoris causâ* are Dr. Byrom Bramwell, consulting physician to the Edinburgh Royal Infirmary, and Dr. F. W. Mott, F.R.S., pathologist to the London County Asylums and physician to Charing Cross Hospital.

Treatment of Ringworm in Edinburgh School Children.

Arrangements have now been completed between the Edinburgh School Board and the managers of the Royal Infirmary for the treatment of cases of ringworm and favus with X rays at this institution. Most of these cases are now under the supervision of the school medical officers, and it has been arranged that the after-treatment of the cases treated at the infirmary is to be in the hands of the nurses attached to the special school which is under the School Board, with the supervision of the medical officers.

Royal Edinburgh Hospital for Sick Children.

While there is still a large deficiency of ordinary income, the directors of this institution note that the amount received from subscriptions and donations exceeds that received in 1912 by £298. The expenses have been, of course, heavier owing to the increased price of coal and household commodities. There have been certain rearrangements of wards in the hospital, whereby eight more beds are available for surgical cases, there being now 69 medical and 50 surgical cots in the hospital. Two of the latter have been set apart for ear and throat cases, under the charge of the aural surgeon, Mr. W. G. Porter. The directors propose to appoint a surgeon-dentist to in-patients, an appointment which is very desirable in every way. The vacancy on the medical staff caused by the retirement of Dr. G. H. Melville Dunlop has been filled by the appointment of the senior assistant physician, Dr. J. W. Simpson, and Dr. N. S. Carmichael has been appointed extra physician in room of Dr. Simpson. In the medical report the following paragraph occurs:—

> Considerable attention has recently been drawn to the prevalence of tuberculosis arising from infected milk in Edinburgh and the neighbourhood. The very important investigations of Mr. John Fraser and Dr. Mitchell were initiated in the hospital, and more than confirm the belief of the staff that tuberculous milk is a very real danger to children. It is easy to ensure the safety of the milk used in the wards, but in an out-patient department the subject is fraught with difficulty for financial and other reasons. The staff trust, however, that the directors will take the matter into their consideration.

April 14th.

IRELAND.

Irish Workhouse Administration.

BEFORE Parliament rose for the Easter recess the Chief Secretary for Ireland furnished a return showing, for a period of 12 months, the salaries, including rations, of officers, the average daily number of inmates, their total cost, the rate per head of this cost, and the percentage of such cost expended in salaries, for each workhouse in Ireland. As the workhouses vary greatly in average population, from 25 in Dunfanaghy to 3914 in South Dublin, it is obvious that the cost per head and the percentage of cost spent in salaries must also vary greatly. In South Dublin, for instance, the cost per head is £19 18*s.* and the percentage on salaries is 17·7, while the figures for Dunfanaghy are £35 10*s.* and 42·6. But even allowing for necessary differences, the contrast between institutions which are fairly comparable reveals curious discrepancies in cost of administration. The figures for South Dublin are fairly comparable with those for North Dublin and for Belfast. In North Dublin the cost is £20 16*s.* per head and 21·2 per cent. is spent on salaries. In Belfast it is £22 per head and 26·5 per cent. on salaries. In Cork, which approaches to North Dublin in population, the cost per head is £18 18*s.*, but 25·6 is spent on salaries. Comparing neighbouring workhouses of approximately equal size the differences are still striking. In Cashel, for instance, in county Tipperary, the cost per head is £24 10*s.* and the percentage on salaries 26·5. In Carrick-on-Suir, in the same county, the cost per head is £20 1*s.*, but the ratio on salaries is 35·4 per cent. In some of the smaller workhouses the figures reached are extraordinary. Killala workhouse costs the ratepayers £45 10*s.* for each of its 25 inmates, and no less than 53·7 per cent. of this is spent on salaries. There seems to be a good case here for active interference by the Local Government Board.

An Approved Society and Medical Certificates.

At the annual meeting of the Irish Drapers' Assistants' Association, a carefully managed Approved Society doing good work among shop assistants, a resolution was passed which has an interesting bearing on the question of certification. It was to the effect that where a certificate could not be obtained from the doctor in attendance on a member "pending the settlement of the dispute which at present exists in the medical profession," the executive should have discretionary powers to dispense with a certificate. The Commissioners have supplied this society with the free services of "medical advisers" throughout the country, but it does not appear that the society values their services very highly.

Sir Christopher Nixon.

I regret to learn that Sir Christopher Nixon has from considerations of health resigned his position as senior physician to the Mater Misericordiæ Hospital, to which he has been attached for many years.

March Weather in Belfast.

In the neighbourhood of Belfast during last March 4·21 inches of rain fell on 25 days, making a total of 10·50 inches for this year. The average rainfall for March is 3·05 inches, so that March has been a wet month, with very little of that "dust" which is said to be "May gold."

Strabane Hospital Inquiry.

Mr. John Coffey, who on behalf of the Local Government Board held some time ago an inquiry into the state of the Strabane Fever Hospital, has now reported that the condition of affairs "has been most discreditable for some considerable time past." As regards the "disgraceful exhibition of temper on the part of both the nurses and the wardsmaid deposed to at the inquiry," the Local Government Board have decided not to remove the suspension on one of the nurses, and they have made a note in their records as regards the other (a temporary nurse), whose services had already been dispensed with. They suggest another trial for the wardsmaid, and in reference to the medical officer they say "there appeared to have been a want of firmness on his part throughout these disputes."

Derry Water-supply.

The city of Derry having for long suffered from an inadequate water-supply the city corporation petitioned the Local Government Board to grant a provisional order to enable them to put in force the powers of the Land Clauses Act for the purpose of taking otherwise than by agreement certain lands required for the purpose of an auxiliary water-supply for the city. Mr. P. C. Cowan, C.E., the chief engineering inspector of the Local Government Board, held an inquiry into the matter in Derry in February, and has now reported that a supply of water—pure and adequate—is needed, and that it must meet the city's requirements at all seasons, as well as the anticipated increase in population. The Local Government Board say they cannot sanction a scheme which is a "makeshift," and they refuse to grant the conditional order: they urge the corporation of Derry to "press forward a comprehensive scheme for the water-supply." The Derry water committee reply that the scheme was only temporary to supply the needs of the city until such time (five or six years) when they could get a large scheme carried out, and they now warn the Local Government Board that if any disaster should overtake the city by reason of water shortage the responsibility for this must rest with the Local Government Board, who have blocked the temporary arrangement.

April 8th.

PARIS.

The Hygienic Condition of the First Army Corps.

M. Lemoine, director of the medical department of the First Army Corps, quartered at Lille, has advanced a curious reason for the superiority of the health statistics of this over other corps throughout France. M. Lemoine modestly takes no credit for the small death-rate and hospital admission rate of this corps, but attributes them to the very unhealthy condition of the people from among whom the soldiers of the First Army Corps are enlisted—viz., the departments of the Nord and the Pas-de-Calais, which consist for the most part of factory workers and miners. These are the most densely populated parts of France and their infant mortality is fearful, the districts being ravaged by epidemic diseases. M. Lemoine, therefore, thinks that the young conscripts of 20 have undergone a rigorous process of natural selection, all the feeble ones having been killed off and the survivors having suffered from the infectious diseases and become immune. They also find in the army hygienic conditions vastly superior to those of their original environment. Moreover, the men of this army corps are split up into isolated groups of not more than 200 or 300, each group having its own barracks, so that in epidemics isolation is easy. In support of this special resistance of the men of the First Army Corps M. Lemoine finds that in other army corps the soldiers coming from these two departments are less frequently on the sick list than the other men. The startling conclusion follows that the hygienic condition of a regiment would be better in inverse proportion to that of the civil population from which the men are drawn.

The Serum Therapy of Acute Myelitis.

M. Netter has succeeded in curing acute infectious myelitis by an original serum therapy. The relation of this disease with infectious poliomyelitis of infancy suggested to him that the two diseases were due to a common agent. Flexner and Lewis's observations have shown that monkeys experimentally infected with poliomyelitis were cured by the injection of serum from monkeys immunised against the disease. M. Netter has applied this principle in the case of man, making use of serum from patients who had recovered from an attack of infantile paralysis at antecedent periods of respectively 4 months and 22 years. The serum was injected in a dose of 10 c.c. daily for nine days into the spinal column of a man, aged 31, who had been seized with a severe attack of acute infectious myelitis, motor paralysis and anæsthesia having already affected the lower limbs and trunk, so that extension to the medulla would undoubtedly have occurred. Three patients whom M. Netter had observed in a similar condition three years ago died in a very short space of time. The present patient, therefore, seemed inevitably doomed; yet after the first injection of the serum considerable amelioration set in, sensibility and motility reappeared, and at the end of some weeks the patient was completely cured, with perfect use of his limbs and able to have recourse without fatigue to walking and sports. This case, at present unique, suggests the possibility of an entirely new method of treatment.

Electrocution in the Bath.

The Société de Médecine Publique et de Génie Sanitaire listened recently to a communication from

Professor Gariel in which he reported two cases of death by electrocution in a bath. The electricity was derived from the electric-light mains and conducted to the metal base of the bath. In one case the current was not more than 110 volts, which is generally considered harmless, but the surface of contact, which represented that of the entire body, was large. In the other case the electric communication was established when the subject caught hold with his wet hand of the metal chain of an electric bell, in which the current was certainly much weaker. Recently a case was noted of a workman engaged in the construction of a new underground railway who was electrocuted on touching an electric lamp with moist hands while his feet were in the water. Much uneasiness is aroused over these recurring cases.

The Serum Therapy of Malignant Pustule.

A new treatment of malignant pustule has been brought before the Académie des Sciences by Dr. Roux. It is based on a very interesting principle, and is credited to M. L. and M. Ch. Fortineau, of Nantes. Relying on the known effects of the introduction of the bacillus pyocyaneus into cultures of anthrax bacilli they treated patients suffering from charbon with cultures of the bacillus pyocyaneus sterilised by heat. A single injection sufficed in most cases. The results were excellent, for out of 50 patients affected with the disease only five died, and these came under treatment when their condition was desperate. All the others were quickly and completely cured.

Microbes and Sunlight.

Mme. Victor Henry has discovered an application of the ultra-violet rays which opens a new path in bacteriology. By exposing cultures of anthrax bacilli to the rays of a mercurial vapour lamp she has shown that if the greater number are killed a certain number still remain which, to adapt themselves for this resistance, are modified in shape, becoming cocci (differing, however, from any known spores) in place of long flexible threads. These cocci have formed a new race which has been serially cultivated without returning to its primitive shape, and which on inoculation into animals has given rise to a new disease presenting characters entirely differing from those of classical charbon. This result suggests the hypothesis, possibly somewhat bold, that the different microbes found in nature are only varieties of a small number of primitive types that have become changed in consequence of a more or less prolonged action of sunlight and of the conditions of their medium.

Compulsory Antityphoid Inoculation.

The Senate having passed the Bill previously passed by the Chamber of Deputies, antityphoid vaccination is henceforth compulsory in the French military and naval forces. But now the Société de Médecine Publique et de Génie Sanitaire, after a brief discussion, has passed a resolution demanding that compulsion shall be confined to the troops leaving for Morocco and other regions infected with the disease, that it shall not apply automatically to all young soldiers on enlistment, and that in every case the regimental medical officers shall be the sole judges for its necessity. The society's reasons are that it is not yet known, and cannot be known for many years, that these inoculations have not serious effects in certain subjects, and do not pave the way for other diseases, particularly tuberculosis. Attention is also directed to the fact that the fear of typhoid fever is the principal argument, on establishing barracks in a town, fo obtaining the necessary sanitation from the civic authorities, and particularly the provision of drinking water. This provision has been often very grudgingly made by the towns, in consequence of the great expense entailed, and very often with an insufficient ulterior surveillance over the sources used. Under these conditions each case of typhoid fever that has occurred has been always used for exerting pressure on the municipal administration to obtain the further sanitation of the town (as to both its civil and its military sections) by the threat of removing the regiment to some other town. Compulsory antityphoid vaccination, by dissipating the dread of typhoid fever, will give rise to a relaxation in the establishment and maintenance of these sanitary services, and thereby to a recrudescence of other diseases, in regard to which the population has benefited incidentally through these improved sanitary conditions.

April 13th.

ITALY.

Reform of the Medical Curriculum.

THE Royal Committee for the Study of University Reform has just issued its report. The proposals of the Subcommission for the Medical Faculties are giving rise to lively discussion in the medical press. The report starts by advising the separation of the degree of Doctor in Medical Sciences from the qualification to practise medicine. It recommends that the medical curriculum shall be divided into two parts, each of three years' duration. The first comprises physics, botany, zoology and comparative anatomy, pharmaceutical chemistry and toxicology, each a course of one year; physiology, two years; human anatomy, three years; and general pathology, one year. At the end of the three years the examination "di maturità" must be passed. The second period of three years is devoted to the subjects of more exclusively professional interest and their application. To take the examination qualifying for practice the candidate must produce certificates of having satisfactorily attended courses of general clinical medicine and therapeutics for three years; general clinical surgery, orthopædics, throat and ear diseases for three years; obstetrics and gynæcology, mental and nervous diseases, eye diseases, skin diseases, hygiene, children's diseases, and pathological anatomy, for one year each. He will be examined in medicine, surgery, obstetrics and gynæcology, and in hygiene, and among the practical demonstrations he will be required to perform a post-mortem examination. For the degree of Doctor in Medical Sciences the examination is to consist of the presentation and discussion of a thesis and the discussion of certain set subjects. The degree is to have a purely academic value and to confer no right to practise. The candidates must present certificates of satisfactory attendance at courses of physiology and general histology, one year; experimental pharmacology, one year; clinical medicine and clinical surgery, three years each; pathological anatomy, one year; mental and nervous diseases, two years; hygiene, one year; and forensic medicine one year, during a period of at least three years subsequent to the "maturità" examination.

Disease of the Milk Teeth.

Professor Angelo Chiavaro, professor of dentistry in the University of Rome, publishes in the *Policlinico*, Sezione Pratica, of Feb. 1st an open letter to the Director-General of Public Health drawing attention to the frequency of disease of the milk teeth, with statistics of an examination of 1000 children between the ages of 3 and 6. These statistics show a percentage of 49·6 of cases of dental caries with 1522 teeth so diseased. 673 children had teeth encrusted with tartar; 66 were suffering from gingivitis; and 14 had true pyorrhœa alveolaris. In 289 cases the jaws did not meet properly. He points out the necessity of proper care and supervision of the temporary teeth for the sake of the children's digestion, and the preservation and proper alignment of the permanent set.

A Curious Incident.

Recently M. Rosa, of Bergamo, was examining a wounded man in the out-patient room of the hospital, when the man who had committed the assault entered and attacked the doctor. The latter was obliged to make use of his revolver and shot his aggressor in the abdomen. He proceeded immediately to extract the bullet. The wound proved not to be serious. The man was placed under arrest in the hospital.

April 11th.

SOUTH AFRICA.

Insane Persons in Prisons.

THE report of the Director of Prisons for 1912, which has just been issued, shows that during that year only 485 lunatics and suspected lunatics were received into penal institutions, as compared with 766 in the previous year. This reduction is doubtless mainly due to the operation of the Prisons and Reformatories Act of 1911, which prohibits the incarceration of lunatics in gaol in districts where lunatic asylums and public hospitals (other than infectious diseases hospitals) are provided. The reduction in the number of persons admitted to penal institutions on the ground of lunacy is especially notable in the case of Europeans. Only 72 European males and 10 European females were so dealt with in the Union prisons in 1912, as compared with 170 and 22 respectively in 1911. The numbers are still, however, large enough to call for further consideration of any possible means of avoiding the necessity for confining lunatics and alleged lunatics in the same institution with criminals. Out of the 485 cases dealt with by the prison authorities, only 318 were certified as insane and removed to lunatic asylums. The remaining 167 were discharged after a period of incarceration.

Miners' Phthisis.

Dr. W. Watkins-Pitchford, the director of the South African Institute for Medical Research, Johannesburg, delivered an interesting lecture recently on the industrial diseases of South Africa. The lecturer devoted himself almost entirely to a consideration of the facts regarding pulmonary silicosis. He pointed out that the Transvaal Miners' Phthisis Commission of 1903 was of the opinion that probably 21 per cent. of all the underground miners were actually or probably affected with silicosis; that a similar commission in 1912, after examining 3135 underground miners, found that 993, or approximately 32 per cent., were suffering from miners' phthisis in one or other of its stages, and that about two-thirds of the cases were in the stage of early or moderate fibrosis. The lecturer considered that, owing to the different manner in which the investigations of these two commissions were carried out, their respective estimates cannot be justly compared. He pointed out, however, that, although the general conditions of underground hygiene were better in 1912 than in 1903, yet the number of rock drills employed had more than trebled in the interval. The director expressed the opinion that a scrupulous obedience to the spirit of the mining regulations would have resulted in the total abolition of pulmonary silicosis from the goldfields of the Rand, but, as he naïvely put it, silicosis still remains a trammel and a menace to the gold-producing industry of South Africa. In other words, the regulations are there, but they are not properly enforced by the Government, and they are disregarded by the miners in their desire to draw big wages even at the risk of health and life.

Medical Matters in Parliament.

Dr. John Hewat recently asked in the House of Assembly what had been done to give effect to the recommendation of the House last session with regard to the appointment of a Leprosy Commission. The Minister of the Interior replied that, after careful consideration, the Government had come to the conclusion that no good purpose would be served by the appointment of such a commission, but it had under consideration proposals for extending the asylum accommodation so as to bring all cases under treatment, and that exhaustive departmental inquiries were already being made. In reply to a question a few days later from Mr. P. G. Kuhn as to whether the Government intended to introduce a Bill to consolidate the Medical Acts of the various parts of the Union, the Minister of the Interior replied that though the Government considered such legislation to be highly desirable it would be unable to introduce such a Bill during the present session.

Report of the Economic Commission.

The report of the Economic Commission, which was appointed as a result of the miners' strike in July last, has been presented to Parliament. The report is not without a medical interest. The Commission considers that the cost of living for whites is about 40 per cent. higher on the Witwatersrand than in America (the most expensive of the other countries examined) and nearly 80 per cent. higher than in any European country. Wages on the Witwatersrand are nearly 40 per cent. higher than in America (where money wages are materially greater than in any other country examined), and nearly 225 per cent. higher than in any European country. When allowance is made for cost of living as a whole it would seem that the workman on the Witwatersrand is better off than the workman in America and much better off than the workman in Europe. The report as a whole is an extraordinarily able document, and it should be of the greatest value to the Government in dealing with the many economic and industrial problems with which it is faced.

March 3rd.

AUSTRALIA.

Tenth Australasian Medical Congress.

THIS congress met at Auckland, New Zealand, on Feb. 14th, and was well attended, a considerable number of Australian practitioners making the somewhat uncomfortable sea trip. The special functions included services at the various churches on Sunday, the 15th; a reception by the President, Dr. A. Challinor Purchas, and Mrs. Purchas on the 14th;

and a congress dinner on the 16th. At the inaugural meeting there were present on the platform His Excellency the Earl of Liverpool, the Prime Minister of New Zealand, the Premier of New South Wales, the Anglican and Roman Catholic bishops of Auckland, and many other distinguished persons. Dr. Purchas delivered an address in which the advances of medical science were noted. The work in the various sections was interesting, particular attention being centred upon the care of the feeble-minded and the prophylaxis of venereal diseases. The special committee on the feeble-minded recommended the establishment of schools and a residential colony for the permanent care of those not fit subjects for asylum detention. A special committee on syphilis presented a report dealing with the evidence collected in New Zealand. The committee recommended—

1. That syphilis be declared a notifiable disease. That notification be encouraged, and discretionary but not compulsory; and that the chief medical officer of health be the only person to whom the notification be made.
2. That provision be made through the Hospital Boards to establish laboratories in the four centres where not already existent for the diagnosis of syphilis.
3. That free treatment in the public hospitals and dispensaries be provided for syphilitics.
4. That steps be taken to educate the Mercantile Marine as to the dangers of syphilis, and that provision be made for preventative treatment on the intercolonial service.
5. That legislation be enacted against the treatment of syphilitics by unqualified persons.

Many social entertainments were arranged, and everyone was delighted with the complete organisation made by the New Zealand profession for the comfort of visitors. The next congress will be held in Brisbane in 1917 under the presidency of the Hon. W. F. Taylor, M.D.

Dr. J. A. Macdonald's Visit.

Dr. J. A. Macdonald, who was the representative of the central organisation of the British Medical Association at the Auckland congress, was entertained at dinner in Melbourne and Sydney by the councils of the local branches of the Association. In Melbourne Dr. Macdonald addressed a crowded meeting of medical practitioners on the National Insurance Act.

The Fight with the Lodges.

The dispute between the medical profession of New South Wales and the Friendly Societies of that State reached an acute stage, and on Dec. 31st all lodge appointments were resigned. Many of the societies at once accepted the agreement proposed by the New South Wales branch of the British Medical Association, and others have since come in. A few groups have held out in the hope of getting outside medical attendance, but none is available. It is said that only one practitioner failed to hold to the general compact, and no practitioners from other States would apply for vacant positions, showing that the profession is strongly organised throughout Australia. In Victoria the societies are considering the terms set out by the Victorian branch, and there is practically no opposition to an increase of rates of payment. There exists, however, a strong objection to the acceptance of a wage limit, and it is possible that trouble may arise from this direction.

Invalid Pensions.

The latest Commonwealth returns show that 19,353 invalid pensions have been granted. There have been 3238 deaths and 757 cancellations, leaving 15,318 in force. These involve a yearly payment of £390,000 per annum. In 15 months under the Maternity Bonus Act a sum of £810,445 has been paid in £5 bonuses.

Lister International Memorial.

Mr. R. H. Russell, F.R.C.S. Eng., announces that Victorian subscriptions to the above fund total £94 12*s.* 6*d.*, and a draft for the amount up to Dec. 31st has been forwarded to the general secretary, Sir J. Rose Bradford.

March 5th.

Correspondence.

"Audi alteram partem."

REVERSED ACTION OF THE HEART.

To the Editor of THE LANCET.

SIR,—The practical point at the end of this letter to which I wish to draw attention must form my excuse for commenting on the curious and interesting fact dealt with in your annotation under the above heading in THE LANCET of March 28th (p. 910). The details of the case in the original supply in a measure a hiatus in the experience of cardiac motor phenomena.

Auriculo-ventricular bradycardia—the *bradycardie sinusale* of the French—is comparatively common, but, as you state, an auricular in excess of a ventricular bradycardia has not hitherto been observed. We only require now to meet with a case in which auricular bradycardia is not associated with ventricular retardation to complete the series of cardiac motor phenomena which has rewarded the careful investigation of cardiac motor disorders which has more recently characterised clinical work in this sphere. This hiatus, too, may, probably will, in time be filled.

Whether, however, a case such as that with which your annotation is concerned is to be regarded as explicable by a reversal of the heart's action may, I venture to think, be questioned. By those who regard the auriculo-ventricular bundle as a survival of the original continuous cardiac tube, such an explanation of the phenomenon referred to may appear probable, but by those who, like myself, do not regard this tract in that light, but as a later developed structure growing forwards into ventricle this interpretation is more difficult to accept. To such a relatively greater prolongation of auricular over ventricular diastole or, what comes to the same thing, a relatively greater postponement of systole in the respective chambers appears to be more reasonably explicable on the assumption of a delay in the cardio-motor nervous mechanism of the heart which governs the action of the chambers *separately*, and for the exercise of which the assumption of a reversal of muscular impulse is not necessary.

There is said, in the unique but doubtless not isolated case to which you refer, to have been no "block," presumably because normal action was after a time resumed and because the *v.-a.* (instead of *a.-v.*) interval, as it would be called in terms of myogeny, remained constant. But in one of the cardiographic illustrations in the original there are two ventricular systoles without auricular response (if the feature regarded as due to auricular systole be really so), and it is stated that full atropinisation had no influence on the peculiar rhythm. The behaviour of the heart was thus the same as that so frequently observed in so-called "block" when the absence of response is on the part of the ventricle.

It is not unusual to find the term "block" used in the description of cases in which several auricular systoles precede a single ventricular systole and in which, nevertheless, the ventricle is not abnormally retarded and is also readily accelerable by atropine. I refer to cases of so-called auricular flutter. In the case which you annotate the use of the term "block" by the myogenist would therefore seem quite permissible. I need scarcely add that, personally, I quite agree that "block" in the sense in which that term is usually employed was absent in this, as, indeed, in all other cases, an emphatic avowal of what is for the moment a heresy, which I do not hesitate to make. I shall be in no way surprised when a case of auricular bradycardia without ventricular retardation is in due course reported and completes the evidence in favour of a neuro-muscular, not musculo-neural, automatism of the heart's action.

Practice in a scientific age is largely influenced by theory and frequently involves the use of powerful agents requiring care in their employment. Among such agents is that invaluable but double-edged weapon digitalis on which so much has been written in recent years, but without adding much to our knowledge of all that is useful in its employment as expressed by some of our predecessors. There is now, however, a tendency to sit so heavily astride the auriculo-ventricular bundle in some cases in which auricular muscular stimulus and conduction are assumed to be concerned, that there is a danger of its over-employment to the detriment of the patient. For this tendency scepticism of a muscular hypothesis is a wholesome corrective and must form my excuse for addressing you.

In writing thus I do not imply that large doses of digitalis are not occasionally required for its effective use, but that the persistence of some cardiac motor disturbances, such as massed auricular extra-systolia or flutter as I regard it, are less objectionable than the attempt to abolish them by a heroic dosage which is less likely to be employed when myogenic conceptions of cardiac action are less in the ascendant.

I am, Sir, yours faithfully,
ALEXANDER MORISON.

Upper Berkeley-street, W., April 10th, 1914.

CANCER HOUSES.

To the Editor of THE LANCET.

SIR,—The paper by Sir Thomas Oliver in THE LANCET of April 4th, and the article in the *Times* of April 6th, have drawn attention to the subject of cancer houses. In 1902, in a presidential address to the South Midland Branch of the British Medical Association, I was able to bring forward 30 instances of two or more cases of cancer living together in one house or intimately associated occurring amongst a population of 102,000 in North Bedfordshire in the decennial period 1890-1899, and in THE LANCET of Nov. 14th, 1903, I published notes of a group of five cases of cancer, three of which died from cancer of the tongue in one village within the space of 16 days. In my own practice I have had 10 instances of dual cancer.

1. A lady died from malignant disease of the sigmoid flexure of the colon in May, 1897, and in July, 1899, her husband died from sarcoma of the adductor muscles of the thigh.

2. A man died in March, 1902, from cancer of the larynx, and for the last two years his widow, who has remained in the same house, has suffered from cancer of the breast.

3. A lady in 1900 had cancer of the small intestine and ovary, which I removed, and died from a recurrence in the uterus in 1901. Her successor in the house, who was not related to her, died from cancer of the uterus recurring after removal of a cancerous ovary in January, 1909.

4. A man, aged 32, died from cancer of the sigmoid in April, 1901, and his father, who afterwards moved to another house, died from cancer of the stomach in February, 1905.

5. A lady had her breast removed for cancer in June, 1909, and an ovarian tumour in December, 1910. Now has recurrence in the glands of the neck. Her husband died from cancer of the stomach in November, 1912.

6. A woman had her breast removed for cancer in April, 1910, and her husband died from cancer of the prostate in August, 1911.

7. A lady died from cancer of the sigmoid in October, 1911, and her husband from cancer of the stomach in February, 1913.

8. A lady had her breast removed for cancer in January, 1912, and her sister-in-law with whom she lived died from cancer of the pharynx in July, 1913.

9. A man died from cancer of the hepatic flexure of the colon in October, 1910. In 1909 his sister, who lived with him, had her breast removed for cancer.

10. A man was operated on for cancer of the rectum in February, 1911, and his wife for cancer of the cervix uteri in March, 1914.

In my experience dual cases of cancer have been far more frequent than dual cases of tuberculosis.

I am, Sir, yours faithfully,
W. GIFFORD NASH, F.R.C.S. Eng.

Bedford, April 7th, 1914.

AN UNUSUAL CASE OF SELF MUTILATION.

To the Editor of THE LANCET.

SIR,—It is inconceivable that the English proverb, "To cut off one's nose to spite one's face" ever had a literal application; equally unlikely, one would think, would it be for a person to cut off his penis to spite his father. Yet such a case has quite recently come under my observation.

An elderly Brahmin of the Tiwari tribe came to the Basti District Hospital; tears were running down his cheeks, and he was carrying something in a clean rag in his hand. I asked him what was the matter, and in broken-hearted tones he described that his son was now 19 years of age and that he had been very anxious to have him married. "Now," he said, "look what he has done." On opening up the rag I found a penis—very full-sized, one might say—with a large piece of the scrotal skin attached to it. The penis had been cut off at the root and was hard and firm to the touch. I asked him where his son was, and he said he was outside under a tree. I went and saw him. He was a lanky youth, about 20 years of age, very pale and ghastly looking. I asked him how it had all occurred, and he described it as follows. His father, like all Indian fathers, was anxious to have his son married to carry on the race, and had been worrying him for some months past about it. At last in desperation he had taken a knife and cut off his penis. It was not painful at the time he did it, but the bleeding was very free. He said he had a great deal of pain now, but he was not anxious to have any treatment or to stay in hospital. He wished to become a sadhu, or holy man, and to lead the simple life, but the father was greatly opposed to it, and that was why the son had cut off his penis. The wound was full of clotted blood, but there was no longer any bleeding. He left the hospital almost immediately and has not returned.

I am, Sir, yours faithfully,
CHARLES MILNE, M.B. Aberd.,
Lieutenant-Colonel, I.M.S.
Basti, United Provinces, India, March 24th, 1914.

UNQUALIFIED PERSONS AND MEDICAL BENEFIT UNDER THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—I am instructed to forward to you for publication in your valuable journal a copy of the following resolution passed by the Royal College of Physicians of London on April 6th in relation to the employment of non-qualified persons for the purpose of medical treatment under the National Insurance Act:—

NATIONAL HEALTH INSURANCE (MEDICAL BENEFIT) REGULATIONS, 1913.

The College observes with regret that in Section 44 (2) of the National Health Insurance (Medical Benefit) Regulations, 1913, and the Memorandum issued in connexion therewith, provision is made whereby insured persons who make their own arrangements for medical benefit under Section 15 (3) of the National Insurance Act may obtain treatment from non-qualified persons.

Hitherto none but duly qualified medical practitioners have been employed, as such, in any public capacity, and the College deplores that, under an Act professing to promote the health of the nation, recognition should be given and provision made for the payment of public money to a class of persons who have not obtained a legal qualification to practise medicine and concerning whose medical knowledge there exists no sort of guarantee.

I am, Sir, yours faithfully,
J. A. ORMEROD,
April 8th, 1914. Registrar.

THE MODERN GAS FIRE AND HYGIENIC EFFICIENCY.

To the Editor of THE LANCET.

SIR,—I have read with much interest the article with this title in THE LANCET of April 4th, and I consider that you are doing excellent work in bringing into prominence the points in connexion with these fires which lead towards greater hygienic efficiency.

I notice that "the fires were tested in the middle of the experimenting room without any communication with the fireplace chimney." I cannot help thinking that this arrangement was hardly fair to the fires, and in any case it is not an arrangement which would be adopted in actual practice. I take it that all the fires tested (with perhaps one exception) were intended to be fixed in a fireplace with an elbow or flue leading into the chimney, and it would surely have been better to have fixed the fires in such a position for the purpose of testing them. With the arrangement adopted it is quite possible that the results of the tests made have been to some extent inaccurate in certain cases, and this would account for what would appear to be inconsistency in the results of the tests shown in the diagrams. As an instance of the inconsistency I would like to point out the difference shown between fire No. 22, Merlin (Wright), and fire No. 25, Talisman (Wright). Under the chemical test the Merlin does not show good results with even a 4-feet flue, whereas the Talisman shows perfect results under all conditions. I believe I am right in stating that the construction of these two gas fires is identical, the only difference being in the shape of the outside casing, the Merlin being round-topped and the Talisman square-topped.

It would be interesting if you could see your way to make a further series of tests with these fires connected to a chimney in the ordinary way.

I am, Sir, yours faithfully,
ARTHUR E. WILLIAMS, A.M.Inst.C.E.
Queen Victoria-street, E.C., April 6th, 1914.

*** We publish with pleasure a natural protest without admitting our inconsistency, because the two fires were not identical in every respect. It was stated in the article that the final appeal must be to the chimney and fireplace. We consider that the gas fire should leave the factory with a hygienic hall-mark, tested under the conditions described, even though they may seem unnecessarily severe.—ED. L.

"THE MENACE OF CANCER" AND AMERICAN VITAL STATISTICS.

To the Editor of THE LANCET.

SIR,—In the letter of Mr. F. L. Hoffman, of New Jersey, U.S.A., published in THE LANCET of April 11th, in which he attacks certain criticisms of American mortality statistics recently published by Dr. Bashford, reference is made to some expressions of mine on the inaccuracy of American mortality statistics as follows: "Dr. Bashford, on the authority of Oertel, claims that New York City has shown that the greatest laxity and inaccuracy obtains, owing to the neglect of the medical profession and the unwillingness of the authorities to enforce the prescribed penalties. The views of Oertel have *not been accepted by qualified critics* (the italics are mine), although justified to *a limited extent* as regards *initial* diagnosis in hospital practice, which has but an *indirect bearing* upon the terminal certification in death registration. *There is no laxity or gross inaccuracy inherent in the vital statistics of the City of New York*, which are accepted by every authority on vital statistics throughout the world. The compulsory registration of deaths has been in force in the City of New York since 1865, but for half a century previous deaths were recorded in a more or less trustworthy manner, and probably as accurately and conclusively as for most of the large cities of the world during the corresponding period of time."

It is not my practice to enter into any public controversy with those who do not agree with me, even where I am misquoted or the meaning of my statements is misrepresented, for the serious reader is most always able to refer to the originals and judge one way or the other for himself. In this instance, however, I feel that I must, in justice to Dr. Bashford and to the large number of your English readers who are probably unable to read the originals, enter a protest against a most misleading statement which bears on its surface the stamp of arrogant ignorance. It is, indeed, regrettable that Mr. Hoffman should have allowed himself to issue such a sweeping condemnation and false interpretation of my remarks without citation of, or reference to, one of the qualified critics upon whose judgment he depends. Here, then, shortly summarised, are the facts which Mr. Hoffman has left to me to supply to the reader.

In an article on the Inaccuracy of American Mortality Statistics published in the *American Underwriter* for May, 1913, I said in substance: First, that clinical or bedside diagnoses of a disease are at the best uncertain even in the hands of experienced physicians and surgeons without objective proof of necropsy, and I demonstrated the truth of that statement not only by mine but Dr. Richard Cabot's (Boston) well-known experience (*Journal of American Medical Association*, Dec. 28th, 1912, p. 2295). Secondly, that this uncertainty and inaccuracy is particularly great in the United States of America, where the importance of necropsies and the study of pathological anatomy which are indispensable to good diagnostic ability have always been grossly neglected. Consequently the American physician generally lacks that objective knowledge of disease which is found where a greater opportunity for studying diseases directly from the cadaver is offered. The disastrous result of this lack of knowledge is necessarily poor diagnostic and critical ability. (I might interpolate that herein rests the great advantage of English and continental medical training.) Now, in order to support this statement by objective evidence for the layman, such as Mr. Hoffman, I selected the largest and most important public hospital in New York City, a hospital used as a teaching institution by the three most important medical colleges in New York and in which good attending physicians and reasonably good records are to be expected, and obtained the results tabulated below. In these cases *not* the *initial* diagnosis, as Mr. Hoffman would have us believe, but the clinical diagnoses *available at the time of death* were compared with the anatomical diagnoses. During the year 1912 this hospital had 3170 deaths, of which only 482, or 15·2 *per cent. came to the* test of a post-mortem examination—a very small number compared to the 80 to 90 per cent. of necropsies in European hospitals. The records of the 482 consecutive necropsical cases were used for a comparison of clinical and necropsy findings. Of these 92 were infants. In practically all these latter the necropsy disclosed important lesions not suspected, but the clinical observation had been too brief for accurate diagnosis, and they were for that reason *not included* in the following classification for comparison of post-mortem and clinical diagnosis.

	Cases.		Per cent.
I. Clinical diagnosis confirmed	87	...	22·3
II. Clinical diagnosis correct, but necropsy disclosed important additional lesions. (Example: Lobar pneumonia diagnosed correctly, but necropsy showed cancer of the uterus in addition)	116	...	29·7
III. Clinical diagnosis partly correct, but other important lesions that had contributed to the diagnosed lesion were found. (Example: Acute peritonitis diagnosed correctly, but necropsy showed a perforated gastric ulcer) ...	54	...	13 8
IV. Clinical diagnosis not confirmed	109	...	27·9
V. No clinical diagnosis	24	...	6·2
	390	...	99·9

It will be seen that the necropsy confirmed the clinical idea of the diseased body in 87 cases only of 390, while in the majority the post-mortem examination revealed important additional evidence, which in a considerable number put the case in an entirely different light after necropsy. ...... Now, when it is further considered that in 133 cases of 390, or 34·1 per cent., diagnosis was either entirely wrong or not made at all, and that in some cases *the clinical diagnoses are recorded after necropsy had been performed*, it will be seen how uncertain or even misleading would be any statistics made up of clinical diagnosis or records alone. Consider further that we possess in this instance only the necropsied records of 482 cases in 3170 and apply the same ratio of comparison to the remaining unnecropsied cases, and that the death certificates do not even show what cases have been confirmed by necropsy, would anyone attempt to use figures or data obtained from such material for serious consideration? Still these figures represent the work of a large public institution used for teaching purposes, with which prominent physicians and surgeons are connected and in close affiliation with medical colleges of excellent reputation. In a subsequent paragraph I added: We move under present conditions (in America) in a vicious circle; our clinical records and death certificates are poor, because our physicians lack the objective training that can be derived only from necropsies and competent teachers. We cannot expect to improve in these respects until this training and knowledge become greater.

Thirdly, I enumerated and mentioned in detail many instances which illustrated the prevalent lack of consideration and responsibility of physicians as well as heads of institutions in regard to the recording of accurate statistics. I quoted from my own rather extensive experiences with the public service in New York and from some other States, and I may say mildly, for I did not propose to create a public scandal, which certain of my evidence certainly would have done, but endeavoured to impress upon physicians, State and municipal officials, and the public alike, the actual state of affairs and the urgent necessity for reform. For this reason I did not, for instance, go into the well-known incompetency and the disgraceful conditions of the coroners' office in New York and many other cities, an office which is responsible for practically all death returns in cases of sudden and "unusual" death, and I even avoided mentioning the powerful influence which the mass of mediocre, ignorant and unfit physicians, whose existence we owe to the inferior and vile medical schools and low educational standards (so well exposed by the Carnegie Foundation), must have on the correctness of death returns in the United States. Even the present State examination in New York stands on a relatively low level as regards testing a man's real knowledge and fitness to practise. It consists of written questions which may be answered with the knowledge of cram catechisms. There exists neither an oral nor a practical test, and a man may be allowed to enter practice in New York who cannot tell the section of a liver from that of a spleen. How can one *trust* the death returns under such conditions?

What I said in my article was, it will be appreciated by all well acquainted with American conditions, not new, but really only a repetition of general knowledge, and recorded once more the well-recognised results of the American wretched educational system which, combined with an unrefined political system, has *been* a serious drawback to American science and progress.

These views, says Mr. Hoffman, have not been accepted by qualified critics. I *do not* know who these are, for Mr. Hoffman, in a manner somewhat unusual in scientific controversy, does not even consider Dr. Bashford worthy of references to verify his statements, but I do know that they have been keeping their criticisms very quiet or published them by private subscription only in which I have not been included. On the other hand, Professor Graham Lusk, in a paper read at the International Medical Congress in London last summer on Medical Education in the United States,[1] says, in referring to the scarcity of necropsy experience in the State and City of New York: "If the physician were sure that, in case of death, his diagnosis would be checked by the pathologist, he would be likely to exercise greater care in his work, and he and his pupils would learn to better understand the limitations of diagnosis. Also, the value of vital statistics would be immeasurably enhanced. And further, this very ill-advised policy on the part of the law-making power (he refers to the severe restrictions in performing necropsies in New York) has had a further effect of discouraging pathological morphology, so that many pathological laboratories have turned attention to experimental pathology, &c. ...... The enforced neglect of morphological pathology has been a grave obstacle in the path of medical progress." There are other statements in Professor Lusk's article which may be read with profit in this connexion—for example, that as recent as 1912 the authorities of the State of Tennessee presented the spectacle of licensing 175 (!) individuals who were not graduates of any medical school whatever, and there are several other States in which it is not even necessary that an applicant for medical licence be a graduate of a reputable medical college. (Few States required any State examination before 1890, many even of the Eastern States not until after 1890.) Furthermore, in 1904 (!), when the Council on Medical Education of the American Medical Association began its activities, there were 166 medical schools in the country. Now there are, fortunately, only (!) 110, in contrast with 21 in England, 20 in Germany, 20 in Italy, and 5 in France; and the Council ranks (1913) only 21 in Class A plus as acceptable medical colleges well organised and thoroughly equipped, giving acceptable courses and requiring for admission one or more years of university science. This is really not, as will be seen, an exceptionally high standard, and this list of 21 does not include some of the New York State and City schools, and is silent about the standards of homœopathic and eclectic institutions and their contribution to the medical proletariat.

Enough has been said, I think, to show again that any statistics based on returns from an uncertain medical profession of such a heterogeneous composition covering a vast territory, difficult to control, largely poorly trained in general knowledge and in anatomical diagnosis in particular, must be taken very cautiously. As pointed out by me, even in New York City and State and some of the other Eastern States conditions are far from satisfactory.

I cannot take up more space of your valuable journal, but I think that if Mr. Hoffman would investigate conditions seriously he would find that the foundations for his statistical conclusions rest on very thin ice. His manner of disposing of my utterances and recommendations and the general misinterpretations which he gives them show that he is far from a scientific understanding of his material. What is more serious, his letter shows both the inaccuracy of passionate annoyance and the tendency to hasty generalisation with which an unfortunately still too large class of Americans resent any criticism of their institutions whatsoever.

I am, Sir, yours faithfully,
HORST OERTEL.

St. James's-street, S.W., April 11th, 1914.

THE FACULTY OF MEDICINE OF THE UNIVERSITY OF LONDON AND EXTERNAL STUDENTS.

To the Editor of THE LANCET.

SIR,—As one of the oldest medical representatives on the standing committee of Convocation I have taken a deep interest in your leading article on this subject of March 21st, and in Dr. Graham Little's two letters that have appeared in your columns. I find myself very much puzzled to reconcile two statements of fact. You say explicitly that all the medical schools but one urged the abolition of the external degree in medicine. The division taken at the last meeting of the Faculty, we are told by Dr. Little, was so close that the transfer of one vote would have produced an absolute equality. Dr. Little in his earlier letter, with its informing analysis of the composition of the Faculty, demonstrated that it consisted almost exclusively of teachers in the incorporated colleges and schools. How is it, then, that the enormous disparity of opinion indicated by your statement is not reflected in the division of the Faculty?

I have a further personal interest in the matter, for as an old Guy's man I am sorry to think that my school may be included in the majority which urged the abolition of the external degrees. This would be a singularly ungracious act, for had it not been for the opportunities provided by these, Guy's would have been deprived of two of its best teachers in my time. The career of one of these, my dear friend the late Dr. Wade, offers one of the most powerful of concrete arguments for the retention of the external degree.

I am, Sir, yours faithfully,
A. PERCY ALLAN.

April 10th, 1914.

** The facts are as stated in our leading article. We refer our correspondent to the Final Report of the Royal Commission on University Education in London, Part IV., p. 179, and to the Appendix to the Fifth Report of the Commission, p. 85 *et seq.*, and p. 142. The statement of evidence given on behalf of Guy's Hospital appears in this Appendix.—ED. L.

THE DEPENDENCE OF ARTHROPATHY ON NERVE INFLUENCE.

To the Editor of THE LANCET.

SIR,—I have read Dr. P. W. Latham's letter in THE LANCET of March 28th with much interest, and am glad to see that he has again brought forward evidence to show that affections of nerves may be followed by a condition resembling rheumatic arthritis or even rheumatoid arthritis. I cordially side with him in all he says, and for many years have carried out the treatment he advocates. I continue to do so, and the more I see of it the more convinced I am that it is one of the most powerful measures at present known for combating intractable arthritis and neuritis. I can readily call to mind two striking cases.

1. The patient was a man, aged 66, who fell down a long flight of steps and injured his left shoulder badly. There was no fracture, and the exact nature of the effects of the accident was never made out. The forearm and hand swelled within a comparatively short time and pain was an early symptom, both in the joint and along the whole arm. As time went on the upper arm wasted, the forearm became œdematous, and the joints of the fingers assumed a rheumatoid aspect. Pain increased in severity in spite of treatment, including massage. The patient emphatically stated that

the latter made him worse. The general health became seriously impaired. At the end of three months he was sent away for change of air and came under my care. I applied a large blister on his back on the left side of the upper dorsal vertebræ, and subsequently kept the raw surface open by means of savin ointment. The effect was most gratifying. Within a few days pain became less and eventually ceased. Six months later the patient wrote saying he was in excellent general health and had a useful arm. In this case, whatever else may have happened, I am certain there was severe neuritis of the brachial plexus.

2. A similar case. Patient aged 57. He fell twice from his bicycle, injuring his left shoulder each time. As in the former case, œdema of the forearm and a rheumatoid condition of the hand set in. Pain became so intense the patient was at times delirious. At the end of about three months he also was sent away from home and I took charge of him. I again resorted to a large blister as before. The result was equally gratifying for a time, but subsequently the head of the humerus became sarcomatous.

In each case a celebrated consultant was called in before I saw the patient, but his suggestions led to no relief of suffering. I mention this in no spirit of vaingloriousness, but merely to emphasise the fact that the blister succeeded when all else had failed. It is generally acknowledged that pain means tension, and in my opinion a blister relieves tension.

Dr. Latham refrains from any suggestion as to why joints become rheumatoid when their nerve-supply is impaired, and makes no mention of germs. I feel strongly that these cannot be put aside. Whatever else may be going on in a swollen joint there is beyond all question a local accumulation of toxins. Germs are a source of extremely irritating toxins, and as no living man is ever germ-free, toxins are being constantly produced in his system. There are many who believe that the application of a blister is followed by an increased leucocytosis and production of antibodies. I personally believe that both micro-organisms and toxins are freely extruded through the raw surface produced by a blister, especially if savin ointment is applied once or twice daily as long as necessary.

I am, Sir, yours faithfully,

Bournemouth, April 3rd, 1914. W. J. MIDELTON.

CHANGES IN THE BLOOD IN SURGICAL SHOCK.

To the Editor of THE LANCET.

SIR,—I think one is justified in expressing considerable surprise at the nature of the admission made by Mr. A. Rendle Short as to his CO_2 estimations. In his original article he describes his technique in these words: "A bandage was tied round the patient's arm, and the skin sterilised with iodine." He now states that only in certain cases was such a bandage applied. What is to be thought of physiological observations in which it is regarded as immaterial whether a profoundly disturbing factor is introduced or not? Mr. Short passes the matter over lightly by suggesting that as the bandage was only applied for about a minute, the blood could not have received much additional CO_2. May I refer him to a paper published in THE LANCET of June 19th, 1909, p. 1741, in which Dr. A. P. Beddard, Dr. M. S. Pembrey, and Dr. E. I. Spriggs record the observation that by bandaging the arm for two minutes they could raise the CO_2 content of the venous blood from one-fifth up to the normal value. As Mr. Short describes the sterilisation of the arm with iodine after the application of the bandage, is he really certain that these operations occupied only one minute?

It may here be remarked that, apart altogether from the matter of bandaging, the CO_2 of the venous blood is a very variable factor, and differs widely in different regions. There are other disturbing factors, so that at best merely a rough estimate is possible from these examinations as to the CO_2 content of the arterial blood. A more accurate method is by analysis of the alveolar air, an impossible proceeding, of course, in Mr. Short's cases. Hürter,[1] however, has shown that blood may be easily and safely taken from the radial artery.

The real object of my note was not to uphold the acapnia theory as opposed to the theory of Crile, but merely to point out a source of fallacy in Mr. Short's protocols. As to the general question, there is a tendency to lose sight of the fact that there are different kinds of shock, and the causes are correspondingly diverse. If any one should doubt, for instance, that shock is associated (to put it at the lowest) with acapnia, let him maintain forced breathing for a sufficient number of minutes, and then after recovering his senses he will remain a sceptic no longer. In surgical shock the degree of acapnia present may be roughly guessed by observing the antecedent pulmonary ventilation. Now in the experiments of Janeway and Ewing, to which Mr. Short refers, and which, by the way, were first published in the *Biochemical Journal* for April, 1913, shock resulted just the same when the CO_2 content of the blood was artificially maintained. Seelig[2] also found that the injection of CO_2 into the veins did not prevent shock artificially induced in dogs. The contention of Janeway and Ewing is that the shock in artificial hyperrespiration was due to inhibition of the venous *return to the* heart. But here let it be noted that the intrapulmonary air pressure induced in these experiments was enormous, sufficient practically to empty the thoracic veins, and therefore by no means comparable to the natural hyperrespiration which takes place in the human subject. Accordingly, the relationship of acapnia to shock in man is not disposed of in such experiments.

The adoption of "spinal" shock by Mr. Short as supplying the clue to surgical shock is to my mind rather unfortunate. Both Yandell Henderson and Janeway and Ewing found the bulbar centres perfectly active, and so the latter authors fall back on "local peripheral causes."

I am, Sir, yours faithfully,

A. G. AULD.

Henrietta-street, Cavendish-square, W., April 4th, 1914.

THE LATE COLONEL J. O. WILL, R.A.M.C.

To the Editor of THE LANCET.

SIR,—We venture to appeal to the charity of those members of the medical profession who are in a position to render help to the widow and family of the late Surgeon-Lieutenant-Colonel J. O. Will, R.A.M.C. The deceased leaves an honourable record of work done in many parts of the Empire. Among many who personally tendered to him their thanks for valued services were the late General Wauchope in South Africa and Sir F. M. Hodgson in St. Vincent after the disastrous eruption in that island.

Early in this year Dr. Will, having retired from the Army, purchased a practice in the village of Dunton Green, near Sevenoaks. After only seven weeks he fell a victim to pneumonia. The evening before his death his eighth child was born, the mother's mental and bodily suffering being increased by a perilous obstetric complication. The widow is left with a family of eight to bring up, the eldest being a girl of 16. A yearly allowance to be made by the War Office represents practically her entire income; under the circumstances no great sum can be expected from the sale of the practice, which was a small one. Her only relatives are not in a position to afford substantial aid; and we feel that many medical men would like to do what is in their power to help.

---

[1] Archiv für Klinische Medizin, 1913, cxiii, 1.

[2] American Journal of Medical Sciences, August, 1913.

The Rev. E. Mort, vicar of Dunton Green, has opened a fund, and any contributions we may receive as a result of this appeal will be added to it and thankfully acknowledged.

We are, Sir, yours faithfully,
JAMES E. BLOMFIELD, M.A., M.D. Oxon.

Sevenoaks, April 14th, 1914.

THE SCHOOL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—It may not have come to the knowledge of some school medical inspectors or assistant school medical officers that an organisation has been formed within the Society of Medical Officers of Health with the object of safeguarding and forwarding their general interests.

On Saturday, May 2nd, at 2 P.M., it is proposed to hold a meeting at 1, Upper Montague-street, Russell-square, W.C., for the purpose of bringing together all those of the above classes who work in the metropolitan area—i.e., in Greater London or neighbourhood. To the rank and file of school medical workers there will be no need at the present juncture to labour the necessity of having some organisation adequately to press their claims, hitherto somewhat overlooked. It is therefore sincerely to be hoped that all those, of whatever rank, who are interested in the present and future welfare of the school medical service will strain a point to attend at the time specified. Those who cannot do so will materially help by sending their names and any suggestions they wish to make to me.

I am, Sir, yours faithfully,
S. B. WALSH.

Hampden Club, Phœnix-street, N.W., April 14th, 1914.

DONATIONS AND BEQUESTS.—By will the late Dame Sarah Annabella Boughey, of Sundorne Castle, Shrewsbury, bequeathed £15,000 for the purchase of land and the erection thereon of a cottage hospital at Newport, Salop, to be called the "Annabella, Lady Boughey Cottage Hospital."—The following institutions will benefit under the will of the late Mr. Frederick Ingle: British Home and Hospital for Incurables, Streatham, £1000; West London Hospital, £1000; St. Luke's House (Home for the Dying Poor), £1000; Maternity Charity and District Nurses Home, Plaistow, £500; Miller General Hospital, Greenwich, £500; Victoria Hospital for Children, Chelsea, £500; All Saints, Hospital, Vauxhall Bridge-road, £500; Westminster Hospital, £550; Western Ophthalmic Hospital, £500; Bolingbroke Hospital, £500; and Metropolitan Convalescent Institution, £500.—Under the will of Mrs. B. S. Grewcock, of Pershore, University College Hospital, London, receives £1500 for the endowing of a bed to be called the "John and Bridget Grewcock Bed," and a similar sum is received by Epsom College for the provision of pensions "for retired legally qualified medical men who from old age, permanent incapacity from illness, reduced circumstances, or other causes in the opinion of the Council are in need of such allowance or pension."

THE NATIONAL INSURANCE ACT.

THE STATE MEDICAL SERVICE ASSOCIATION.

A PUBLIC meeting was held recently in London at the Essex Hall by the State Medical Service Association, under the presidency of Sir George Kekewich, when Sir John Collie moved the following resolution:—

> That this meeting, being of opinion that the present arrangements for the prevention and treatment of disease are wholly inadequate to the needs of the community, calls upon the Government to establish a complete State Medical Service, freely available to all, as the only means by which the health of the nation can be efficiently maintained.

Sir John Collie, in proposing the resolution, dwelt upon the difficulties attending the prevention of malingering under the Insurance Act and of consequent excess of disbursement on sickness benefits. He spoke of the institution of a medical service as inevitable when the dependents of those now insured became entitled to medical attendance. Professor Leonard Hill, in seconding the resolution, dwelt upon the advance of medical science in the direction of prevention, and advocated a medical service as a means of combining the prevention with the treatment of disease. Mr. A. G. Gardiner and Dr. A. Salter also spoke, the latter describing the difficulties which under existing circumstances tended to render inadequate the supply of medical men in working-class districts. He further pointed out that whereas the Chancellor of the Exchequer had estimated that about 30 per cent. of the insured patients on a practitioner's list would be attended by him in the course of a year, the secretary of the British Medical Association had estimated that in the light of experience about 65 per cent. would be much nearer the mark. According to the speaker's personal experience in his own practice and of that of other medical practitioners in the East-end, from 82 to 92 per cent. of the insured had to be seen in the year. In order to provide the necessary increase in the numbers of the medical profession he recommended the democratisation of the profession, and made suggestions as to the lines upon which education for this purpose might be arranged. The resolution was carried.

MANCHESTER INSURANCE COMMITTEE AND CRITICISM OF PANEL PRACTICE IN MANCHESTER.

Dr. T. A. Helme, at a recent meeting of the Manchester Insurance Committee, made a vigorous speech with regard to the allegations of inadequate medical service at Manchester, the consideration of which has been referred to a subcommittee. Resolutions of the Medical Committee were read, *calling the Insurance Committee's* attention to (*a*) the insufficiency of medical remuneration, the income available having proved hitherto less by £70,000 than what would be necessary to pay medical men on the panel on the official scale arranged; (*b*) the insufficiency of the drug fund to provide and in particular to its inadequacy for the provision of the most appropriate remedies for many serious cases; (*c*) unfair charges publicly made of malpractice and careless treatment, resulting in resentment and consequent lack of interest in insurance work on the part of medical men. Dr. Helme declared that patients had been given under the Act as good treatment as they had enjoyed as private patients before it. He impugned the honesty of the attacks made upon the medical profession. The allegations were untrue in fact and unfair in the manner in which they had been made. The medical practitioners themselves had constituted a special committee for the sifting of complaints carefully and dispassionately round a table where laymen and medical men would do their best for the insured. The persons making charges had not used the official means provided for the purpose, and he would challenge them to bring definite cases before the committee. He made on behalf of the medical profession in Manchester a cordial offer to them to do their very best to make the Act a success if possible. After the chairman had made some observations it was resolved to refer the resolutions of the Local Medical Committee to the Special Committee already appointed.

BRISTOL INSURANCE COMMITTEE.

At its last meeting this committee considered several matters of medical interest. The chairman said that, in response to a request for information offered by some of the panel practitioners, the remuneration per visit had been calculated on a wide and representative basis. It worked out at about 1*s.* 4½*d.* per visit. Negotiations are proceeding for the allocation of those persons who have not yet chosen a doctor. A resolution devoting the unallocated funds formed by the allowance for these persons to the provision of home nursing and other benefits for the insured was carried by a large majority; an amendment proposing its delay for further consideration of the claims of the panel to receive this money being negatived. It was stated that premises accommodating about 24 patients would shortly be open, in addition to those already available, for the reception of tuberculous patients for sanatorium treatment.

PANEL PATIENTS AND EXTRA FEES.

At a meeting of the Leicestershire Insurance Committee a resolution was passed to the effect that medical men on the panel should be reminded by a recommendation forwarded by the Committee that insured persons on their lists were entitled to the benefits provided by the Act without charge, and that it should be intimated that the committee would view with disfavour any suggestion made by any medical man that patients should make any additional payment.

LEICESTER ROYAL INFIRMARY.—The opening ceremony of the reconstructed Children's Hospital in connexion with this institution will be performed by the Hon. Mrs. G. Murray Smith, on Wednesday next, April 22nd, at 3.15 P.M.

BRITISH HOSPITALS ASSOCIATION.—The fifth annual conference of this association will be held at Newcastle-upon-Tyne from June 18th to 20th, 1914. The Lord Mayor of the city (Councillor Johnstone Wallace, J.P.) will preside and deliver an address, and various papers dealing with hospital matters will be read and discussed. Full particulars of the conference will be announced in due course.

MR. H. W. ARMIT, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Editor of the *Medical Journal of Australia*, and will leave England to take up his duties this month. The *Medical Journal of Australia* will replace the existing *Australasian Medical Gazette* and *Australian Medical Journal*, and the offices will be situated in Sydney, New South Wales.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Quarterly Examination in Practical Pharmacy, held on April 2nd, the following candidates were approved :—

Finlay Cameron, King's College and Charing Cross Hospital; Hugh Collins, Madras and London Hospital; Eric David Despard Davies, Cambridge University and St. Mary's Hospital; Frederick Graham Leslie Dawson and George Stanley Deane, London Hospital; Horace Silva Drabble, Sheffield University; Hassell Dyer Field, St. Thomas's Hospital; Luis Hernando Garces, London Hospital; Ralph Byron Gibson, Sheffield University; Arthur Dodsworth Haydon, Cambridge University and St. Thomas's Hospital; Arthur Maddock Jones, Charing Cross Hospital; Tom Jones, Cambridge and Manchester Universities; Theodore Louis Kan, King's College and St. Thomas's Hospital; Felix Edward Ricardo Laborda, Guy's Hospital; Constantine Lambrinudi, Cambridge University and Guy's Hospital; Eric Delafield Lindow, King's College Hospital; Archibald Daniel Marston, Guy's Hospital; Benjamin Robert Mayman, King's College Hospital; Bhamini Mohan Mitra, Calcutta and Middlesex Hospital; Leonard William Mortimer, London Hospital; Noel Spencer Nairne, St. Thomas's Hospital; Guy William Parry, St. Bartholomew's Hospital; Sachchidananda Hosen Paul, Calcutta and Charing Cross Hospital; Frederick Stanley Lawrence Piggott, Cambridge University and St. Thomas's Hospital; Herbert Sharpe, Cambridge University and Guy's Hospital; Bawa Harkishan Singh, Lahore Medical College and Middlesex Hospital; Robert Masters Somerset, Sheffield University; Frank Hugo Stuttaford, St. Mary's Hospital; Samuel Leon Szpigner, London Hospital; Karl Johan Fredrick Westman, Guy's Hospital; Henderson Whyte, London Hospital; and Thomas Wilson, Manchester University.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following were the successful candidates at the examination held at the end of the forty-fourth session (January–April, 1914) :—

G. G. Jolly (Colonial Service) and N. S. Williams (with distinction), G. M. Millar (Colonial Service), C. J. B. Pasley (Colonial Service), A. L. Fitzmaurice, V. StJohn Croley, J. Marmion, I. Ridge-Jones, S. Colyer, S. F. Chellappah, Bernard Haigh, E. Gibson (Colonial Service), Miss E. N. M. Ross, and J. H. Castro.

UNIVERSITY OF GLASGOW.—At the Final Professional Examination, held recently, the following candidates were successful :—

Robert Armstrong, George Flett Barr, Robert William Brander, William Hunter Brown, Ethel Crawford, Robert Frew, Adolph Robert Hanns Geyer, Alexander John Gibson, Thomas Gilchrist, David Hardie, John Wishart Welsh Hewitt, David Johnston, George Smith Livingston, Daniel Steel M'Bean, Charles Robertson M'Intosh, Jessie Gordon M'Laren, Neil Macleod, Frederick William M'Millan, Robert Martin M'Minn, Ewen Stewart Macphee, James Kennedy Manson, William Strelley Martin, Walter John May, William Meikle, Alexander Dryden Moffat, William Luddington Peacock, John M'Lean Pinkerton, David Reid Eccles Roberts, Robert Cecil Robertson, Stanley Robertson, Stuart Robertson, Stuart Dewar Robertson, Archibald M'Kerrow Russell, John Fraser Steven, Henry Stewart, John Symington Stewart, Ronald Stewart, Ian Dishart Suttie, Robert Tennent, Robert Noel Thomson, William Thomson, John Cuthbertson Walker, Henry Currie Watson, Sara Adam Watson, Grace Birrell Whish, Alexander Sweet Wilson, and Thomas Wilson Wylie.

At the examinations for the degrees of M.B. and Ch.B. the following candidates passed with distinction in the subjects indicated :—

Zoology and Chemistry.—James Rognvald Learmonth, Peter Alexander Mackay, John William Peden, and Agnes Petrina Routledge.
Botany.—Donald Maclean.
Zoology.—John Barlow, Barclay Barrowman, Thomas M. Burton, Margharita Mary Lamont Couper, John Donald, William John Ferguson, Grace Anderson Fleming, Tom Osborne Howie, Robert Ebenezer Kerr, Elizabeth Cochrane Loudon, and Isabella Quarrier M'Fadzean.
Physics.—Thomas Robertson.
Chemistry.—Isaac Ladipo Oluwole.
Anatomy and Physiology.—Thomas Arthur Letters.
Materia Medica and Therapeutics.—David Campbell and Clive Alan Whittingham.
Pathology and Medical Jurisprudence and Public Health.—Ernest M'Murchie Dunlop.
Pathology.—John Mandeville Macfie.
Medical Jurisprudence and Public Health.—John Glaister and John Desmond Milligan.
Surgery and Clinical Surgery and Practice of Medicine and Clinical Medicine.—Robert Tennent.
Surgery and Clinical Surgery.—George Flett Barr, Stanley Robertson, and Stuart Robertson.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.—At examinations held recently the following candidates passed in the examinations as undernoted.

Preliminary Examination.—Daniel Casey, Baron Asher Cohen, Edward Patrick Connolly, David Clein, John Duffy, Joseph Forbes, John Francis Gallagher, Thomas Philip Harper, Daniel Hegarty, Thomas Joseph Hurley, John Joseph Lee, James McAleer, Thomas Fulton McCay, Christopher MacCormack, Peter Eugene Macnamara, Thomas F. Minford, Victor Franz Von Nauman, Joshua Pousner, Patrick Joseph Roddy, and Louis Scher.

First Professional Examination.—Henry Bell, William E. Cooke, Thomas N. D'Arcy, Sylvester J. Healy, Timothy Lynch, Thomas H. K. McLoughlin, Victor J. J. O'K. Murphy, Carl O'Connor, Bernard F. O'Reilly, and Gilbert R. Wilson.

Second Professional Examination.—M. Briscoe (with honours), J. P. Morgan (with honours), J. F. Seale (with honours), D. J. Steele (with honours), J. H. Barrett, J. J. Bourke, G. H. M. Crofts, W. O'C. Hunt, H. Levison, and J. E. Lucas.

Third Professional Examination.—C. H. Brennan, W. E. R. Dimond, J. A. Fretton, J. A. McKinnon, A. C. McQuaide, G. M. Moffatt, T. F. Moran, V. A. Power, R. O'C. Redmond, A. P. Reilly, N. E. Stephens, and M. A. Sullivan.

Final Examination.—Charles M. G. Campbell, Ernest Connell, James J. Donegan, Joseph J. Elliott, Edward Green Foley, John M. Gilmor, William Lumley, Louis L. McKeever, John A. O'Driscoll, Patrick J. O'Reilly, James J. Reynolds, and Robert P. Weldon.

Diploma in Public Health.—Henry Blyth, M.B. Edin., Capt. Howard Crossle, I.M.S., M.B. Dub. (with honours), and Henry Lloyd, M.D. Durh.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND TUBERCULOSIS.—We are asked to say that the "statement concerning the infectivity of tuberculosis," which was adopted by the council of the College at its last Comitia and summarised in our report last week, can be had on application at the College, Pall Mall East, London, S.W.

THE ROYAL SANITARY INSTITUTE.—A lecture will be delivered at 90, Buckingham Palace-road, S.W., on Wednesday, April 29th, at 5 P.M., by Dr. E. F. Bashford, director of the Imperial Cancer Research Fund Laboratory, on "The Bearing of Comparative and Experimental Investigations on the Association of Cancer with Chronic Irritation."

HUNTERIAN SOCIETY.—The last meeting of the session will be held on Wednesday next, April 22nd, in the library of St. Bartholomew's Hospital. After the election of officers for next session, the winner of the society's annual medal, Dr. B. T. Parsons-Smith, will read a paper, founded on his prize essay, and dealing with the intermittent pulse. The society's silver medal and certificate will then be presented to him by the President.

GUY'S HOSPITAL.—An invitation is extended to medical men to attend a course of six lectures on "Industrial Medicine," to be delivered at the Medical School of this hospital by Dr. Frank Shufflebotham, lately Milroy lecturer on that subject at the Royal College of Physicians of London. The lectures will be given on Fridays at 4 P.M., commencing on May 8th, and will be illustrated by the epidiascope, by pathological specimens, and by clinical cases.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Easter Holidays.

THE House of Commons adjourned on Wednesday, April 8th, until Tuesday, April 14th, for the Easter holidays.

HOUSE OF COMMONS.

TUESDAY, APRIL 7TH.

Uncertified Deaths.

Mr. HIGHAM asked the President of the Local Government Board what was the statutory authority for the amended regulations recently issued by the Registrar-General on the subject of uncertified death; whether the regulations had been advertised in the *London Gazette*, in pursuance of Section 44 of the Registration Act 1874, and, if not, why were they not so advertised; and whether the regulations forbade registrars to register such deaths until they had been dealt with by the coroner, or whether it was intended that the registrar should register such deaths as heretofore, and then report them to the coroner, if this had not been done already.—Mr. HERBERT SAMUEL replied: The statutory authority for the regulations referred to is Section 5 of the Births and Deaths Registration Act, 1836, which does not require their publication in the *London Gazette*. As regards the last part of the question the new regulations follow the previous regulations in providing that in all cases in which the registrar reports to the coroner he must await the coroner's decision before registering the death.

WEDNESDAY, APRIL 8TH.

Flies as Carriers of Infection.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether his attention had been called to the warning recently addressed to the public by 123 medical officers of health as to the prevalence during the summer months of infantile enteritis and other diseases traceable to the common house fly, and the increased human mortality consequent thereon; and whether the Board were taking any, and if any what, steps to effect the reduction of the fly population and of the diseases caused thereby.—Mr. HERBERT SAMUEL replied: The answer to the first part of the question is in the affirmative. As regards the last part of the question the Local Government Board are fully alive to the importance of this matter. They have issued six reports on flies as carriers of infection. They have warned local authorities by circular both in 1911 and 1913 of the danger of allowing accumulations of refuse which may form breeding grounds for flies to remain in their districts, and they have for some time been urging individual local authorities who are not dealing satisfactorily with the refuse of their districts to improve their methods.

Medical Officers of Health in Scotland.

Replying to Mr. ASTOR, Mr. MCKINNON WOOD (Secretary for Scotland) wrote: In Scotland there are 134 medical officers of health. Of these, 33 are full-time officers and 101 are part-time officers. Of the whole-time officers 16 have salaries of £500 or over and the remainder receive less than £500.

Sleeping Sickness in East Africa.

During the debate on the East African Protectorates (Loan) Bill, Mr. L. HARCOURT (the Colonial Secretary) mentioned that inquiries were still being made by a committee at the Colonial Office into the subject of sleeping sickness in East Africa. It presented a difficult problem, which was also being investigated on the spot. He warned honourable Members against running away with the idea that game or domestic animals were the only carriers of the disease.

TUESDAY, APRIL 14TH.

Funds for Sanatorium Purposes.

Mr. MONTAGU (Secretary to the Treasury) informed Mr. F. HALL (Dulwich) that the question of giving special facilities for loans from the Local Loans Fund for Sanatorium Purposes was under consideration.

Beds for Jews in Sanatoria.

Mr. GODFREY LOCKER-LAMPSON asked the President of the Local Government Board whether the Jewish board of guardians had reported that there was no large increase in the total number of beds in sanatoria available for Jews.—Mr. HERBERT SAMUEL answered: The reply is in the affirmative, but no complaint has been made to me that the number is inadequate.

Domiciliary Treatment in Perth.

Mr. GODFREY LOCKER-LAMPSON asked the honourable Member for St. George's-in-the-East, as representing the Insurance Commissioners, whether the Perth Insurance Committee had so far neglected to provide domiciliary treatment for consumptives; whether this neglect had followed as a result of a conference with the Scottish Insurance Commissioners; and, if so, whether the Government would take steps to see that this necessary treatment was provided.—Mr. WEDGWOOD BENN replied: I am informed that there is no foundation for the statement in the first part of the question. Both in the burgh and in the county of Perth, as in all other parts of Great Britain, domiciliary treatment is provided for under the doctors' agreements with the Insurance Committee. No conference of the kind referred to by the honourable Member has been held, and the last part of the question does not therefore arise.

Ireland and Medical Benefits.

Mr. A. HENDERSON asked the Chancellor of the Exchequer whether he intended to make an attempt this session to secure the passage of the Bill to extend medical benefits under the National Insurance Act to insured persons in Ireland.—Mr. WEDGWOOD BENN (who replied) said: I regret that in my right honourable friend's unavoidable absence I am unable to make any statement.

Milk and Dairies Bill.

Replying to Mr. CHARLES BATHURST, Mr. HERBERT SAMUEL said that he hoped to be able to introduce the Milk and Dairies Bill shortly.

Preservatives in Cream.

Answering Mr. HUME-WILLIAMS, Mr. HERBERT SAMUEL (President of the Local Government Board) said: For the period 1909–12 inclusive legal proceedings in respect of cream containing added preservative resulted in convictions in 74 cases. Of the 74 samples of cream in question 21 contained less than 0·25 per cent. of boric acid, 39 samples contained between 0·25 and 0·5 per cent., and 14 between 0·5 and 0·75 per cent. Complete information is not available for any later period.

Mr. HUME-WILLIAMS asked the right honourable gentleman (1) whether his attention had been called to the confusion existing in the dairy trade owing to the fact that no regulations had been made defining the amount of preservative which might legally be added to cream before it was sold; whether it was his intention to issue such regulations, and if so, when; and (2) whether his attention had been called to the fact that on August 11th, 1909, Dr. J. M. Hamill, one of the medical inspectors of his department, made a report in which he recommended that 17½ grains to the pound of boric acid might without injury to health be added to cream during the cooler months of the year and 28 grains to the pound during the months from May to October; and whether he would take that report as the basis for regulations to be issued with reference to the use of preservatives in cream.—Mr. HERBERT SAMUEL replied: I have received representations to the effect that an alteration of the regulations is desirable, and the matter is receiving my consideration. As at present advised I am not satisfied that an official recognition of a limit of preservative is desirable.

WEDNESDAY, APRIL 15TH.

Uncertified Deaths.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether his attention had been called to the recent speech of Sir Charles Cameron, M.D., formerly M.P. for the College Division of Glasgow, when presiding at the annual meeting of the Cremation Society, in which he protested against the scandalously lax requirements of the burial law which afforded every facility for the concealment of crime and conduced to the compilation of worthless statistics, and alleged that death certificates given by medical practitioners were filled up in a most perfunctory manner, too often on hearsay and without personal knowledge, and that many thousands of deaths were each year registered which were not certified by any medical practitioner; whether, in the opinion of his advisers, such allegations were well-founded; and, if so, whether it was proposed to introduce legislation dealing with this matter.—Mr. HERBERT SAMUEL said in reply: I have not seen a report of the speech referred to. Under a recent Regulation issued by the Registrar-General uncertified deaths are required to be reported to the coroner. With respect to the last part of the question, the Registrar-General is considering the question of what amendments are desirable in the law relating to the registration of births, deaths, and marriages, but I am not at present in a position to made any statement as to legislation on the subject.

Mr. BATHURST: Is the right honourable gentleman not aware that death certificates are given in a very unprecise manner by medical practitioners at the present time?—Mr. HERBERT SAMUEL: I would not be prepared to make any sweeping condemnation of the manner in which medical practitioners perform the duties cast upon them, but I have no doubt that there are defects in a certain number of cases.

BOOKS, ETC., RECEIVED.

Maidstone, Kent County Asylum.—Fourth Assistant Medical Officer, unmarried. Salary £200 per annum, with quarters, attendance, washing, &c.

Manchester Children's Hospital (Out-patients' Department), Gartside-street.—Assistant Medical Officer for six months. Salary £50 per annum.

Manchester, Monsall Fever Hospital.—Third Medical Assistant. Salary £130 per annum, with board, lodgings, and washing.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—Honorary Physician for Diseases of Children. Also House Surgeon.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary at rate of £85 per annum, with board, residence, and laundry.

Newark-upon-Trent Hospital.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and laundry.

Newcastle-upon-Tyne, Corporation City Hospital for Infectious Diseases.—Resident Medical Assistant. Salary £200 per annum, with board, lodging, &c.

Newcastle-upon-Tyne, Hospital for Sick Children.—Junior Medical Officer for six months. Salary £80 per annum, with board, lodging, and laundry.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Resident Medical Officer and Assistant Resident Medical Officer. Salaries £200 and £150 per annum respectively, with board and residence. Also Medical and Surgical Registrars.

Norfolk Education Committee.—Assistant School Medical Officer. Salary £250 per annum.

Nottingham General Hospital.—Assistant House Physician. Salary £100 per annum, with board, residence, and laundry.

Oldham Royal Infirmary.—Senior House Surgeon and Second House Surgeon for six months. Salary £140 and £120 per annum respectively, with residence, board, and laundry.

Preston Royal Infirmary.—Resident Medical and Surgical Officer, unmarried. Salary £150 per annum, with board, residence, and laundry.

Prince of Wales's General Hospital, Tottenham, N.—Senior House Physician. Salary £75 per annum, with residence, board, and laundry. Also Pathologist. Salary 120 guineas per annum. Also Honorary Medical Registrar.

Reading, Royal Berkshire Hospital.—Second House Surgeon for six months. Salary at rate of £80 per annum, with lodging, board, and washing.

Rochdale Infirmary.—Senior House Surgeon, unmarried. Salary £110 per annum, with board, residence, and laundry.

Rotherham Hospital.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Royal College of Surgeons of England.—Election to the Court of Examiners.

Royal London Ophthalmic Hospital.—Assistant Surgeon.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and laundry.

St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City-road, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

Salisbury Infirmary.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, lodging, and washing.

Sheffield Royal Infirmary.—House Surgeon and Ophthalmic House Surgeon for six months. Salary £80 per annum each, with board and residence.

Sheffield Union Hospital, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, rations, &c.

Southampton, Royal South Hants and Southampton Hospital.—Junior House Surgeon. Salary at rate of £100 per annum, with rooms, board, and washing.

Stoke-on-Trent, North Staffordshire Infirmary, Hartshill.—House Physician, unmarried. Also Casualty and Out-patient Officer, unmarried; for six months. Salary at rate of £110 per annum each, with board, residence, and washing.

Stroud General Hospital.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

Throat Hospital, Golden-square, W.—Honorary Dental Surgeon.

Tottenham Education Committee.—Assistant School Medical Officer. Salary £300 per annum.

Trinidad, British West Indies.—Three Medical Officers required to Conduct Campaign against Ankylostomiasis. Medical Officer in Charge, salary £600 per annum. Two Assistant Medical Officers, salaries £400 per annum.

Wakefield, West Riding Asylum.—Locum Tenens Assistant Medical Officer. Apartments, board, &c.

Walsall and District Hospital.—Senior House Surgeon and Assistant House Surgeon. Salary £150 and £110 per annum respectively, with board, residence, and laundry.

Warrington, Lancashire County Asylum, Winwick.—Locum Tenens Medical Officer for about five months. Board, apartments, attendance, and washing provided.

West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Out-Patients' Physician.

West Ham Union Sick Home, Forest-lane, Forest Gate.—Second Assistant Resident Medical Officer. Salary £160 per annum. Also Female Assistant Medical Officer at Workhouse, Union-road, Leytonstone, N.E. Salary £140 per annum.

West Hartlepool, Cameron Hospital.—House Surgeon, unmarried. Salary £120 per annum, with rooms, board, &c.

West London Hospital, Hammersmith, W.—Ophthalmic Surgeon.

Westminster Hospital.—Surgical Registrar. Salary £50 per annum.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with board, apartments, and washing.

Wolverhampton and Staffordshire General Hospital.—Resident Medical Officer. Also Two House Surgeons. Salary in each case £125 per annum, with board, rooms, and laundry.

Woolwich Infirmary, Plumstead.—Assistant Resident Medical Officer, unmarried. Salary £180 per annum, with apartments, rations, and washing.

Workington, Borough of.—Lady Health Visitor. Salary £25 per annum.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Kirkcaldy, in the county of Fife.

Births, Marriages, and Deaths.

BIRTHS.

Addison.—At Prestwood, Great Missenden, on Easter Sunday, the wife of Dr. Christopher Addison, M.P., of a son.

Callender.—On April 5th, at Inverard, Sidcup, the wife of Thomas Marshall Callender, M.D., F.R.C.S. Edin., of a daughter.

Steadman.—On April 7th, the wife of F. St. J. Steadman, D.P.H., M.R.C.S., L.R.C.P., L.D.S., a daughter.

Warner.—On April 7th, at The Square, Fakenham, Norfolk, the wife of Howard F. Warner, M.B., B.S. Lond., of a son.

MARRIAGES.

Philp—Fussell.—On April 16th, at Upton St. Leonards, Gloucester, by the Rev. A. J. Rendle, M.A., Vicar of Bleddington, Glos., brother-in-law of the bride, assisted by the Rev. Canon Brewster, Rector of the Parish, Claude Hastings Philp, B.A., M.B., B.C. Cantab., only son of Mr. and Mrs. G. Hastings Philp, of The Wells, Podsmead-road, Gloucester, of Cantilupe House, Hereford, to Margaret, youngest daughter of the late W. F. Fussell, of Mells, Somerset, and Mrs. Fussell, of "Carnarvon," Bournemouth.

Sladden—Williams.—On April 15th, at Dowlais, Arthur F. S. Sladden, M.D., second son of Julius Sladden, of Badsey, Worcestershire, to Mary Christabel Williams, third daughter of the Rev. Ll. M. Williams, Rector of Dowlais.

Smith—Johnston.—On April 11th, at the Cathedral, Newcastle-on-Tyne, Henry Gordon Smith, M.B., B.S. Lond., D.P.H., to Alice Grace, daughter of James Harvey Johnston, of Newcastle-on-Tyne.

DEATHS.

Charlton.—On April 13th, at Glendarroch, Lenton, Nottingham, Alfred Charlton, M.B., C.M.

Collyer.—On April 9th, at Paignton, South Devon, Bertram Joseph Collyer, M.R.C.S., L.R.C.P., aged 44 years.

Hilder.—On April 9th, Ridley Thomas Hilder, M.B., M.R.C.S., of Teviot House, Upper Tooting, London, S.W., and Cockfield, Suffolk, in his 70th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PROPOSED NEW PHARMACY LEGISLATION.

THE Assistants to Chemists and Druggists (Qualification) Bill, which is now before Parliament, seeks to introduce into pharmacy law a new principle. The main effects of the existing Pharmacy Acts are to protect certain pharmaceutical titles and to restrict to registered chemists and druggists the sale of poisons, these measures being based upon the assumption that the public is best protected from the misuse of poisons by educating the poison seller. There is nothing apparently in these enactments to prevent persons who are not qualified from compounding medicines providing the actual sale of preparations containing scheduled poisons is performed by registered pharmacists. To some extent, however, the National Insurance Act corrected this deficiency by providing that medicines for insured persons should be dispensed either "by or under the direct supervision of a registered pharmacist or by a person who, for three years prior to the passing of this Act, has acted as a dispenser to a duly qualified medical practitioner or a public institution." This provision only applies to medicines for insured persons, and leaves untouched the question of medicines prescribed by medical practitioners for their private patients. An extension of this principle is aimed at in the new Bill, which appropriately enough has been drafted by the Pharmaceutical Society in pursuance of a promise made while the Insurance Bill was before Parliament that steps would be taken to promote a measure to make provision for dispensers. The first clause of the Bill proposes to make it an offence for "any person, who not being a duly registered chemist and druggist, or registered under this Act, acts as assistant to a chemist in compounding any medicine prescribed by a duly qualified medical practitioner." The usual reservation is, however, made for medical practitioners who desire to dispense their own medicines, and there is an exemption in favour of registered apprentices who compound medicines under the supervision of registered chemists. To make more secure the object of the first clause, a subclause prohibits chemists from employing non-registered assistants for compounding medicines. With the exception of certain persons who would be eligible for registration as assistants without examination, those desirous of being registered would be required to pass an examination, and the Bill proposes to empower the Council of the Pharmaceutical Society to make by-laws enabling them to establish an examination, and, in fact, to regulate the proper carrying out of the provisions of the measure. Qualified military dispensers, certified assistants under the Apothecaries Act, and persons who had been for not less than three years immediately preceding the passing of the Bill employed by a medical practitioner or by a chemist as an assistant in compounding medicine, would be entitled to registration without examination. These are briefly the provisions of a measure which appear to be based upon a sound principle, but the probability of the measure reaching a final stage during the present session of Parliament seems to be remote.

GLYCOSURIA AND THE SUGAR INDUSTRY.

To the Editor of THE LANCET.

SIR,—I should like to know if people (white and coloured) living and working on cane sugar estates are subject to glycosuria, and if so are there any statistics on the subject? Perhaps some of your readers would be able to furnish the answer through the columns of your valuable journal.

I am, Sir, yours faithfully,

F. C. MACNALTY, M.D. Dub.

Winchester, April 13th, 1914.

VITAL STATISTICS OF BERMUDA.

IN a belated report on the Blue-book for 1912 of the Colony of Bermuda (a cluster of small islands situated in the west of the Atlantic Ocean, in 32° 15' N. lat. and 64° 51' W. long., comprising an area of about 19 square miles), Mr. R. Popham Lobb, the Colonial Secretary, gives the estimated total population, including the naval and military establishments, as 22,073. The resident civil population numbered 19,591 (7,000 white (3,3[illegible] males and [illegible] females) and 12,5[illegible] coloured (6,0[illegible] males and 6510 females). The birth-rate was 33·22 (22·57 per 1000 white and 37·15 per 1000 coloured). The mortality during the year was exceedingly low. The death-rate among the [illegible] was [illegible] per 1000, [illegible] 12·32 for white and 15·[illegible] for coloured. The deaths of children under 5 years of age formed 40·5 per cent. of the total deaths. There has hitherto been no hospital maintained by the Colonial Government, but during 1912 an Act was passed providing for the building of a general hospital, to be known as the King Edward VII. Memorial Hospital, of which the surgical unit and operating-room are being in the first instance erected. There is a cottage hospital near the city of Hamilton which is supported by voluntary contributions, and hospitals are also maintained in connexion with the Imperial naval and military establishments. There is a lunatic asylum under the superintendence of the medical officer of health, and the number of patients in this institution at the end of the year was 65. The mean temperature of the air in 1912 was 71·1°. Rain fell on 167 days, the total rainfall registered being 51·38 inches, of which 35·9 per cent. fell in the two months of July and August. The islands are much frequented as a health resort by Americans and Canadians, and the number of tourists who arrived during 1912 was 24,830. Many additions have been made to the smaller hotels and several new ones started.

BUSINESS METHODS IN THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—That medical men are unbusinesslike is proverbial, but I have never before come across quite such a document as the one, headed "Balance Sheet for 1913," which has just reached me from the Metropolitan Police Surgeons' Association.

In the first place it is not usual to head a balance sheet with "Dr." and "Cr." but with "Assets" and "Liabilities." On the right-hand side of this balance sheet—the side usually reserved for assets—occurs the item "musical entertainment, £5 5s." How such item finds its way into a balance sheet I know not, unless the unfortunate musicians have not yet been paid for their services, in which case I would respectfully suggest that the item should be transferred to the other side of the page to figure amongst the liabilities. Of course, this document is *no* "balance sheet" at all, but simply a "cash account." This being so, may I point out that cash received is "Dr." and cash paid out is "Cr.," and not the reverse as herein stated. Further, it is usual for "Dr." to appear on the left side of the page and "Cr." on the right, not *vice versâ*.

Finally, I observe that the item for "Printing and postages" represents a sum equivalent to 45 per cent. of the year's income. Surely I cannot have received my due supply of literature.

Can it be a fact that this association possesses no assets beyond its cash balance? If so, I would congratulate the honorary treasurer on his marked success in getting in all his annual subscriptions before the end of the year, and the members on their promptness in paying.

Perhaps I may be told that outstanding subscriptions and other assets are included in the "balance" shown in this document. If this be so, then I erred in calling it a "cash a/c," and will substitute the words "capital a/c," in which case the "income" and "expenditure" appear on their wrong sides of the page.

In short, it is a hopeless muddle.

I am, Sir, yours faithfully,

April 11th, 1914. A METROPOLITAN POLICE SURGEON.

THE WORKMEN'S COMPENSATION ACT: A NOVEL POINT.

AT Tavistock, Devon, before his honour Judge Lush-Wilson, K.C., the point was raised whether the illegitimate child of a second wife, not by her husband, should be treated as her husband's stepson, and consequently become a *dependent* and entitled to a share of the compensation money. His honour said it was a nice point, but eventually decided against the child being allowed compensation.

CLIMATOLOGY.

Italian.—With regard to the effects of mountain climates on man there is the Italian work of Professor Angelo Mosso on the "Life of Man on the High Alps" (T. Fisher Unwin, London), 1898, translated from "Fisiologia dell'Uomo sulle Alpi" (Frat. Treves, Milano), 1897. The best work is still probably "Höhenklima und Bergwanderungen in ihrer Wirkung auf den Menschen," by Professor Dr. N. Zuntz, Professor Dr. A. Loewy, Dr. Franz Muller, and Dr. W. Caspari, published by the Deutsches Verlagshaus Bong und Co., Berlin W.57, Potsdamerstrasse 88, and Leipzig, Wien, Stuttgart and Paris, first edition, 1906, which contains references to most previous publications on the subject. Since then there have appeared many articles on portions of the subject by various authors—e.g., works by Dr. J. S. Haldane, "Methods of Air Analysis," published in 1912 at 5s. net by Charles Griffin and Co., Limited, London, and articles in the German "Zeitschrift für Balneologie." In regard to the effects of sea air and mountain air generally, reference should be made to "Climatotherapy and Balneotherapy," by Sir Hermann

Weber, M.D., and F. Parkes Weber, M.D., third edition published in 1907 at 15*s.* net by Messrs. Smith, Elder, and Co., 15, Waterloo-place, London; and "A Handbook of Climatic Treatment, including Balneology," by William R. Huggard, M.D., published at 12*s.* 6*d.* net by Messrs. Macmillan and Co., Limited, London. Of the former book (Weber) a shorter German version was published (Paul Mayer) which has been in its turn translated into French, Russian, and Polish, but not into Italian.

PRECIPITATE LABOUR.

A CURIOUS case of attempted concealment of birth occurred recently in Australia. A popular pleasure steamer left Melbourne for Geelong to pick up the members of a picnic party. A few passengers had embarked at Melbourne, and while steaming down the bay the body of a recently born infant was found on the floor of the female lavatory. A police constable who happened to be on board was informed, and he interviewed all the female passengers at once, but no one admitted to the ownership of the infant. Suspicion fell upon a young woman who was seated in the company of a young man, and she was detained on arrival at Geelong. She subsequently admitted having given birth to the child on the steamer, and she and the infant were removed to hospital. The child died next morning. The case has a medico-legal interest, as the steamer would not occupy more than an hour and a half on the run between the two jetties.

HEALTH OF ST. VINCENT.

THE Administrator and Colonial Secretary of St. Vincent, the Hon. C. Gideon Murray, in his report for 1912–13, just presented to Parliament, gives the population of the colony as 44,434. The births registered during the year numbered 1678 (of which 59·83 per cent. were illegitimate), as against 1790 in the preceding year. The deaths totalled 878, being 19·75 per 1000 of the estimated population; the infant mortality constituted 21·07 per cent. of the total number of deaths. In the towns the authorities are realising more and more the importance of stricter sanitation and are taking steps accordingly. In the villages, however, sanitary matters are still on a primitive basis. The establishment of an organised sanitary department now under contemplation should have far-reaching effect. A trained nurses' association has recently been formed, which has for its object the better training of nurses and midwives and the prosecution of women practising midwifery illegally. Early in the year 1911–12 the old military hospital was renovated and opened as a yaws hospital capable of holding 50 patients. The disease of yaws has long been ravaging the homes of the labouring population in the colony, and the institution of this hospital is much appreciated by them. The introduction of salvarsan has more than doubled the number of patients passing through and out of this hospital as cured during the year. The rainfall for the year was 94·89 inches, as against 119·07 inches in 1911–12. Rain fell on 275 days during the year. The mean monthly temperature was 78° F.; the maximum for the year was 80·6° in September and the minimum 73·5° in February. Except in August and September, when the atmosphere is uncomfortably hot, although not even in those months insalubrious, the climate may be regarded as most healthy for both Europeans and coloured persons. Malaria is hardly known, while yellow fever has proved itself to be a disease of the past. The approaching opening of the Panama Canal is already causing an influx of visitors to these Caribbean seas, and if exquisite scenery and a healthy climate be inducements to travellers, then as years speed on it may be expected that St. Vincent will be one of the most favoured tourist spots amongst the many beautiful West Indian Islands.

ROAD RULES FOR PEDESTRIANS.

Dr. C. W. Hutt, senior school medical officer to the county borough of Brighton education committee, inquires where he can obtain some simple road rules for the use of children attending elementary schools, so as to prevent as far as possible their being run over in the streets. He has an impression that he saw a reference to some such rules a few years ago in one of the medical journals. His intention is to send them to the head teachers of the elementary schools with a view to their being explained and taught to the children.—We believe that one of the leaflets issued lately by the London General Omnibus Company gave simple rules for pedestrians crossing the road. A correspondent in this connexion has sent us these rules, which apply to traffic in large towns: "Pause on the curb facing the roadway; look to right and then to the left. If the road is reasonably clear, cross to the middle, where pause and look to the left; if course is clear, proceed to opposite curb. When crossing, face slightly the approaching streams of traffic. Avoid running, but be ready to spring suddenly if danger threatens. When dismounting from a vehicle always make for the nearest curb immediately, no matter where you want to go afterwards."

Mr. F. Hiller.—The makers of Dr. Rogers' "Tycos" sphygmomanometer are Messrs. Short and Mason, Limited, Macdonald-road, Walthamstow, London, N.E.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 15th–18th (Berlin).—Forty-third Congress of the German Surgical Society.
" 19th–21st (Berlin).—"Jubilee" Congress of the German Röntgen Society.
" 20th–23rd (Wiesbaden).—Thirty-first German Congress for Internal Medicine.
" 27th–May 1st (London, Royal Horticultural Hall).—Nursing Conference and Exhibition.
May 1st–Nov. 1st (Lyons).—International Town Hygiene Exhibition.
" 15th–Oct. 15th (Berne).—Swiss National Exhibition.
May 18th–21st (London, Imperial Institute).—Victoria League Imperial Health Conference.
May–October (London, Shepherd's Bush).—Anglo-American Exposition.
June 8th–10th (Berne).—Seventh International Dairy Congress.
" 18th–24th (London, Church House, Westminster).—International Conference on the Blind.
June–July (Groningen).—University of Groningen 300th Anniversary Celebration.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—F. Langmead, Philip Turner, W. J. Midelton): at 4.30 P.M.

Demonstration of Cases.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Paper:

Dr. Harold Kerr and Professor H. J. Hutchens, D.S.O.: An Outbreak of Food Poisoning caused by the Bacillus Enteritidis (Gaertner) in Milk.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Cases will be shown. 5.15 P.M., Discussion on Some Dermatological Problems, opened by Dr. P. White (Wigan).

CHELSEA CLINICAL SOCIETY, Club Rooms of the Medical School, St. George's Hospital, S.W.

TUESDAY.—8.30 P.M., Papers:—Dr. E. G. Reeve: Some Points in the Administration of Intensive Nascent Iodine Treatment.—Dr. H. Dally: Some Observations on the Intense Nascent Iodine Treatment. A discussion will follow.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Osteoma. (Museum Demonstration.)

FRIDAY.—5 P.M., Prof. Keith: The Comparative, Surgical, and Pathological Anatomy of the Great Bowel. (Museum Demonstration.)

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. H. B. Carlill: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: The Diagnosis of Hepatic Abscess.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.15 P.M., Sir Malcolm Morris: Skin.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. B. Carlill: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery. 3.15 P.M., Special Lecture:—Mr. L. V. Cargill: The Routine of Ophthalmoscopic Examination.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. H. R. Prentice: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Dr. C. E. Zandel: Tachycardia.

FRIDAY.—Out-patient Demonstrations:—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin. ——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford: Medicine. 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. B. Prentice: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. B. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women, and Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear, and Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

MONDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Cardiac Department, Dr. Stott; Out-patient Department, Dr. Phear, Dr. S. Thompson. 3 P.M., Wards, Dr. Phear.

TUESDAY.—9 A.M., Laryngological Department, Mr. Mant. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. M. Leslie, Dr. B. King; Operations, Mr. A. Evans. 3 P.M., Wards, Dr. White. 4 P.M., Wards, Dr. M. Leslie

WEDNESDAY.—2 P.M., Wards, Dr. A. Davies; Out-patient Department, Dr. Drysdale, Dr. Kellie. 4 P.M., Wards, Dr. Drysdale. 4.30 P.M., Roentgen Ray Department, Dr. Jordan.

THURSDAY.—9.30 A.M., Dental Department, Mr. G. Thomson. 10 A.M., Cardiac Department, Dr. Stott. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. Phear, Dr. S. Thompson. 4.30 P.M. Laryngological Department, Mr. Mant.

FRIDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Wards, Dr. Calvert; Out-patient Department, Dr. M. Leslie, Dr. B. King.

SATURDAY.—10 A.M., Out-patient Department, Dr. Drysdale, Dr. Kellie. 11.30 A.M., Roentgen Ray Department, Dr. Jordan.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY.—3 P.M., Lecture:—Dr. J. Atkinson: Suppuration in the Region of the Pharynx.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

LONDON LOCK HOSPITAL, 91, Dean-street, Soho, W.

Special Course of Instruction in Venereal Diseases, for Post-Graduates and Students, with Practical Demonstrations of the Various Methods of Treatment:—

MONDAY.—Clinics:—1 P.M., Mr. Ryall; 6 P.M., Mr. Gibbs.

TUESDAY.—Clinics:—2 P.M., Mr. Lane; 6 P.M., Mr. Paterson.

WEDNESDAY.—Clinic:—6 P.M., Mr. Shillitoe.

THURSDAY.—Lecture:—2 P.M., Mr. Lane: The Primary Chancre, its Varieties, Diagnosis, and Treatment.

SATURDAY.—Clinic:—2 P.M., Mr. McDonagh.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

TUESDAY.—MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.—4.30 P.M., Prof. R. B. Wild: Radium in Dermatology.

WEDNESDAY.—ROYAL INFIRMARY.—4.30 P.M., Mr. Buckley: Hæmaturia.

THURSDAY.—ANCOATS HOSPITAL.—4.15 P.M., Dr. D. E. Core: Clinical Examination of the Nervous System.

UNIVERSITY OF SHEFFIELD, at the University.

Post-Graduate Course on Syphilis:—

TUESDAY.—3 P.M., Dr. H. Henry: Biology of the Spirochætes.

FRIDAY.—3 P.M., Dr. H. Henry: The Spirochæte of Syphilis (with cinematograph illustrations).

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The following journals, magazines, &c., have been received:—Journal of Surgery, Monthly Cyclopedia, Journal of Tropical Medicine and Hygiene, South African Medical Record, Dublin Journal of Medical Science, Clinical Medicine, Quarterly Journal of Experimental Physiology, Annales de l'Institut Pasteur, Revue de Gynécologie, Policlinique, International Journal of Surgery, Calcutta Medical Journal, American Journal of Tropical Diseases and Preventive Medicine, American Journal of Medical Sciences, Revue de Médecine, [illegible], Revue de Chirurgie, Archives de Médecine et de Pharmacie Militaires.

Communications, Letters, &c., have been received from—

A.—Dr. T. L. Ashforth, Doncaster; Mr. R. Charles Alexander, Edinburgh; Aerators, Ltd., Lond.; Messrs. Armour and Co., Lond.; Dr. F. S. Arnold, Bovingdon; Messrs. Arnold and Sons, Lond.; Ardath Tobacco Co., Lond.; Argyll County Council, Lochgilphead, Clerk to the; Anglo-American Pharmaceutical Co., Croydon.

B.—Dr. S. A. Bonnerjee, Calcutta; Messrs. Bayer Co., Lond.; Birkenhead Guardians, Clerk to the; Birmingham and Midland Free Hospital, Secretary of; Captain J. A. Bennett, R.A.M.C., Youghal; Dr. C. Burnham, Ross; Bolton Infirmary, Secretary of; Birkenhead and Wirral Children's Hospital, Secretary of; Messrs. Butterworth and Co., Lond.; Messrs. Battee and Co., Brussels; Dr. R. M. Buchanan, Glasgow; Dr. W. A. Brend, Lond.; Bristol Royal Infirmary, Secretary of; Bristol City Asylum, Secretary of; Messrs. W. H. Bailey and Son, Lond.; Dr. T. Ridley Bailey, Bilston; Dr. Boni, Florence; Dr. Andrew Balfour, Curaçao.

C.—Mr. H. Curtis, Lond.; Messrs. Chesterton and Sons, Lond.; Messrs. Carnrick and Co., Lond.; Dr. H. W. Cattell, Philadelphia; City Asylum, Bristol, Clerk to the; Cremation Society of England, Lond., Secretary of; Cannon Iron Foundries, Deepfields; Messrs. E. Cook and Co., Lond.; Central London Throat and Ear Hospital, Lond., Secretary of; Mr. H. A. Collins, Croydon; Chesterfield Hospital, Secretary of; County Asylum, Prestwich, Superintendent of; Dr. Donald E. Core, Manchester; Charity Organisation Society, Lond.

D.—Messrs. W. Dawson and Sons, Lond.; Mr. T. Dixon, Lond.; Durham County Asylum, Winterton, Secretary of; Mr. A. H. Diplock, Lond.; Derby Corporation, Medical Officer of Health of; Messrs. D. Davis and Co., Lond.

E.—Dr. A. R. Eates, Lond.; Eccles and Patricroft Hospital, Secretary of; Empire Life Insurance Co., Atlanta; Dr. T. R. Elliott, Lond.

F.—F. A. Ensign Advertising Agency, Pittsburgh; Fermanagh County Hospital, Enniskillen, Secretary of; Major M. H. G. Fell, R.A.M.C., Farnborough; Mr. Paul P. Foster, Lond.; Major F. G. FitzGerald, R.A.M.C., Guston; Factories, Chief Inspector of, Lond.

G.—Mr. W. Grisewood, Liverpool; Messrs. Gordon and Gotch, Lond.; Gas Light and Coke Co., Lond.; Galen Manufacturing Co., Lond.; Mr. Cecil J. Graham, Lond.; Guest Hospital, Dudley; Messrs. Godsell and Barnett-Smith, Lond.; Guildford, Medical Officer of Health of; Dr. J. G. Garson, Eversley; Miss R. V. Gill, Lond.

H.—Hereford County and City Asylum, Burghill, Clerk to the; Mr. T. D. Harries, Aberystwyth; Messrs. Hanna and Neale, Dublin; Halifax Union, Clerk to the; Dr. S. M. Hepworth, Kacha Thana; Mr. T. Hunt, Wellington College; Mr. George Hirth, Munich; Hospital for Sick Children, Newcastle-on-Tyne, Secretary of; Dr. G. P. Humphery, Cambridge; Hunterian Society, Lond.

I.—Invalid Asylum and Stoke Newington Home Hospital for Women, Lond.; International Stamping Machine Co., Lond.

J.—Mr. H. W. Jackson, Lond.

K.—Kidderminster Infirmary, Secretary of.

L.—Messrs. Lee and Martin, Birmingham; Dr. Lozano, Zaragoza; Mr. H. K. Lewis, Lond.; Lancashire County Asylum, Winwick, Clerk to the; Leicester Guardians, Leicester, Secretary of; Miss Leeming, Littlehampton; Dr. S. Lilienstein, Bad Nauheim; Leicester Royal Infirmary, Chairman of; London General Information Service, Lond.

M.—Mr. R. W. Murray, Liverpool; Dr. G. G. Mecredy, Bagenalstown; Manitoba Medical College, Winnipeg, Secretary of; Mr. R. Martin, Banbridge; Manchester Royal Infirmary, Secretary of; Metropolitan Hospital, Lond., Secretary of; Manchester Corporation, Town Clerk of; Manchester Northern Hospital, Secretary of; Dr. A. Philip Mitchell, Edinburgh; Mr. R. A. McAllister, Baltimore; Mr. E. R. Moritz, Lond.; Dr. Charles Milne, Basti; Dr. D. G. Macleod Munro, Lond.

N.—North Lonsdale Hospital, Secretary of; Newcastle-upon-Tyne Corporation, Clerk to the; National Temperance League, Lond., Secretary of; Lieutenant-Colonel E. A. R. Newman, I.M.S., Calcutta; Nurses' Co-operation, Lond., Secretary of; National Hospital for the Paralysed and Epileptic, Lond., Secretary of.

O.—Messrs. Osborne Peacock Co., Manchester; Mr. Joseph Offord, Lond.; Oxford University Press, Lond.; Mr. Edmund Owen, Malham; Mr. C. Orchardson, Los Angeles.

P.—Dr. T. Wilson Parry, Lond.; Mr. F. H. Preston, Lond.; Messrs. C. Pool and Co., Lond.; Prince of Wales's General Hospital, Lond., Director of; Mr. C. A. Pannett, Lond.; Preston Royal Infirmary, Secretary of; Post-Graduate Society, Lond.; Public Trustee, Lond.

R.—Dr. Ernest Roberts, Boscombe; Royal College of Physicians, Lond., Registrar of; Mr. H. L. Reynard, Newark-on-Trent; Richmond Gas Stove Co., Lond.; Mr. L. Ryba, Moscow; Messrs. Robertson and Scott, Edinburgh; Royal Orthopædic and Spinal Hospital, Birmingham, Secretary of; Royal Berkshire Hospital, Reading, Secretary of; Royal Society of Medicine, Lond., Secretary of; Dr. Joseph Rivière, Paris; Sir William Ramsay, Lond.; Mr. H. Richardson, Lond.; Royal Halifax Infirmary, Secretary of; Dr. C. Russ, Lond.; Mr. C. Redgrave, Lond.

S.—Dr. Sydenham, Exmouth; Messrs. G. Street and Co., Lond.; Messrs. Spiers and Pond, Lond.; Sunderland Royal Infirmary, Secretary of; Messrs. Sherratt and Hughes, Manchester; Mr. S. J. Stonehouse, Hove; S. M. H.; Dr. J. H. Sheldon, Reading; Mr. Spencer Sheill, Dublin; Dr. Edgar Schuster, Oxford; Sheffield Union, Clerk to the; Stroud General Hospital, Secretary of; Dr. E. Smith, Lond.; Sell's Advertising Agency, Lond.; Mr. T. Strangeways, Cambridge.

T.—Dr. A. K. Traill, Halifax; Messrs. W. Thacker and Co., Lond.; Toronto Housing Co., Toronto, Secretary of.

U.—Dr. Yngvar Ustvedt, Christiania.

V.—Dr. G. Valenti, Premero; Victoria Hospital, Burnley, Hon. Secretary of; Messrs. J. W. Vickers and Co., Lond.; Dr. Walter Verdon, Lond.

W.—Mr. J. Willing, Lond.; Messrs. W. J. Wilcox and Co., Lond.; Messrs. Wilsons and Mathiesons, Lond.; Workington Corporation, Clerk to the; Westmorland Sanatorium, Grange-over-Sands, Medical Superintendent of; Mr. B. Whitehouse, Birmingham; West Bromwich and District Hospital, Secretary of; Dr. S. A. K. Wilson, Lond.; Dr. F. Parkes Weber, Lond.; Dr. David Waterston, Lond.; Wolverhampton General Hospital, Secretary of; Mr. J. Williams, Bradford.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. A. G. Anderson, Ventnor; Accrington Corporation, Accountant to the; A. D., Wimbledon; Army and Navy Male Nurses' Co-operation, Lond., Secretary of.

B.—Dr. C. W. Brown, Manchester; Dr. A. W. Brodrib, St.-Leonards-on-Sea; Dr. R. Brown, Kenley; Dr. D. Brown, Greenock; Bedwellty Union, Clerk to the; Messrs. J. L. Bullock and Co., Lond.; Birmingham Corporation, Treasurer to the; Mr. J. A. Oswald Briggs, Nottingham.

C.—Mr. M. R. Callender, Reading; Dr. H. G. Carlisle, Heswall; Cameron Hospital, West Hartlepool, Secretary of; Cumberland and Westmorland Asylum, Carlisle, Clerk to the; Dr. J. G. Christie, Buckie; Major L. P. Colat, Paris.

D.—Mr. J. D. Davidson, Perth; Mr. C. E. Dashwood, Newburgh; David Lewis Colony, Manchester, Secretary of; Doncaster Royal Infirmary, Hon. Secretary of.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County & Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

The Lumleian Lectures

ON

SOME MODERN THEORIES CONCERNING HYSTERIA.

Delivered before the Royal College of Physicians of London on March 19th, 24th, and 26th, 1914,

BY J. A. ORMEROD, M.D. OXON.,
F.R.C.P. LOND.,

REGISTRAR TO THE COLLEGE; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE.

LECTURE I.

Delivered on March 19th.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—The first part of my task, and a most pleasant part, is to thank you, Sir, and the Censors for appointing me to the honourable post of Lumleian lecturer. But when one considers the long line of distinguished Fellows who, since the reign of Queen Elizabeth, have delivered these lectures, including the greatest of our Fellows, William Harvey, one may well feel diffident in occupying this place. And perhaps I feel the more diffident because I am simply your Registrar, a person whose chief ambition must now be to keep the annals of the College as accurately as my predecessor—if, indeed, that be possible. But I do not doubt, Sir, that in making this appointment you had a precedent in view—namely, that in 1835 and on several subsequent occasions a well-known Registrar of this College, Dr. Francis Hawkins, was Lumleian lecturer. And I may say, Sir, that I, too, have a precedent for the choice of my subject, not only in the interesting Bradshaw lecture on Hysteria, which you heard last autumn from Dr. T. R. Glynn,[1] but also in the fact that Dr. Thomas Mayo, one of your eminent predecessors in the Presidential chair, delivered in 1842 Lumleian lectures on Nervous Apoplexy, Palsy, and Hysteria. And further, looking to the modern doctrine that hysteria is a kind of mental disability, it is interesting to note that Dr. Mayo wrote a book entitled "Elements of the Pathology of the Human Mind." But I cannot find that he correlated the two subjects in any way.

HYSTERIA AND NEURASTHENIA.

Between those diseases which are the peculiar province of the alienist, sometimes called psychoses, and those nervous diseases which we call organic and consider to be *due to* some definite bodily change, there lies a large class of affections to which we apply the vague but convenient term "functional nervous diseases." Sometimes we call them "neuroses," and the people who are prone to them "neurotics." Now this large class falls into several groups. The distinction between these groups is difficult, because in dealing with them we are bereft of the sure support of morbid anatomy. Yet some of these distinctions can easily be made. First, at the organic end of the scale appear several well-known and very definite diseases, which can only be called "functional" in a very qualified and provisional sense, since it seems certain that they have some physical or chemical basis, though we do not yet know it. Such diseases are epilepsy, migraine, chorea, and others. But beyond these as we pass from the organic to the psychical there come two groups of very common nervous affections concerning the bodily nature of which we know so little, that a tendency has now arisen to neglect this aspect of them and to study them chiefly from the side of psychology. These two groups are hysteria and neurasthenia: the first recognised from the early days of medicine, the second modern in name, though I suppose not in reality. Most of us will agree, I think, that we have in them two distinct types of disease, though of course there may be cases in which they overlap. Indeed, tables are laid down in text-books of the clinical points of difference between them. I will here only mention two of these differences.

1. That in hysteria we expect to find, at some time in the course of the disease, outward and visible symptoms, such as fits, paralysis, anæsthesia, and the like, which are objective at least in this sense that they force themselves on the attention of the physician, whereas in neurasthenia the symptoms are subjective and cannot be verified by observation. 2. That the patients have a different mental outlook; to the neurasthenic his symptoms are always a source of distress and may be a burden to his whole life, whereas the disabilities of the hysterical patient (perhaps I should say the confirmed hysterical patient) tell far less upon her, and she may even bear her cross with complacency; in short, the reality of the disease appears in the one case greater to the observer, and in the other to the patient.

But we must admit that in order accurately to define either of these diseases we must have a theory as to the essential nature of it, seeing that there is no easy physical means of recognising them, like the bacillus in tubercle, or the hepatised lung in pneumonia. I shall endeavour, Sir, in my second and third lectures to lay before you some of the current theories about hysteria.

The Nature of Functional Nervous Disease.

Now the first difficulty in theorising about these diseases is to settle whether we are to look on them as mental or as bodily affections. I do not propose to discuss neurasthenia in these lectures, but perhaps I may be allowed to say a few words about it in illustration of this difficulty. Under this general term "neurasthenia" are included several groups of cases. There are the patients described by Beard—perhaps we may call them simple neurasthenics—who suffer indeed from subjective feelings of exhaustion and incapacity, but whose principal symptoms—pains, headaches, backaches, giddiness, palpitations—might well be, and generally are, ascribed to physical causes. Then there are the neuropaths described by Dejerine, whose physical functions appear to be deranged, for they are unable (it may be) to walk, or sleep, or swallow, or micturate properly, yet no organic disease can be found in them, and Dejerine traces their complaints back to mental and moral causes. Lastly, there are the psychasthenics of Janet, in whom the psychical element is obviously preponderant, who are tormented by obsessions, doubts, crises of mental agitation, phobias, or by inarticulate and inexpressible feelings of distress—so-called borderland cases, though they do not always cross the border so as to become insane. Are all these classes of neurasthenics suffering from the same disease? And if we say, as appears incontrovertible, that the psychasthenic is affected mentally, then what of the simple neurasthenic? Why cannot he face his day's work? Has he some physical affection—say, malnutrition or toxæmia (if you like these words) of his nerves and muscles, or is he, too, a psychoneurotic, who is suffering from a mental depression, and has forgotten the truth of the song of Autolycus—

---

[1] THE LANCET, Nov. [illegible], 1913, p. [illegible].

> A merry heart goes all the way,
> Your sad heart tires in a mile-a?

Now while the clinical delimination of hysteria is more easy than that of neurasthenia, because it is a more definite type of disease, yet there is the same difficulty in discussing its nature. Is it a mental or a bodily disease? There are those who look on it as a problem in physiology, to be solved by knowledge of the anatomy, chemistry, and functions of the brain. There are those who would solve it by psychological methods. I think it is no contradiction to say that both are right. It is a question of difference in their points of view, their methods of work, and perhaps their predilections. As to the point of view, if I was to hold up to you, Sir, say half a crown, you might say it was heads, I from my side of the table should have to say it was tails. Not that I should be contradicting you, Sir, unless indeed I forgot that the two faces are indissolubly connected, just as there is some unknown but certain connexion between mind and matter. And as to the method, the physiologists and psychologists are like two gangs of workmen excavating opposite ends of a tunnel; they may hope to meet some day if they have a due regard to the direction of each other's work. But I am afraid the physiologists are apt to think that the psychologists' work is child's play, mere beating the air; whereas the psychologists retort that the physiologists have reached a stratum much too hard for them to work—namely, the task of exhibiting mental phenomena in terms of nerve cells and nerve fibres.

SYMPTOMS OF HYSTERIA.

Anyhow there exist these two ways of regarding functional nervous disease, and probably it will be a long time before they are satisfactorily combined. Now I propose, Sir, to defer for the present the consideration of systematic theories of hysteria, and in this lecture merely to review some of the symptoms of the disease in such a way as to show that it is not always easy to choose between the physiological and psychological explanations, or to adopt one to the exclusion of the other. And if in so doing I travel over familiar ground, I must plead in excuse that for the purpose in hand the common symptoms are perhaps more valuable than the less well known.

Hysterical Fits.

The hysterical fit or paroxysm has always been considered one of the most characteristic features of the disease. The points of diagnosis between the fits of hysteria and those of true epilepsy or of Jacksonian epilepsy are so well known that I need not repeat them. But, indeed, there are as great differences between the varieties of hysterical fits *inter se*. Consider the simple hysterical fit as described by Briquet, corresponding to the popular "fit of hysterics," in which the patient feels a lump in the throat or some other odd sensation, sinks into a chair, gives a mild emotional display of gesticulation, tears, or laughter, and speedily comes to again, having never lost consciousness of her surroundings or passed beyond the reach of help from her friends. How greatly does this differ from the hystero-epileptic fit as described by Charcot, in which the patient loses consciousness and unfolds a regular panorama of striking, one might almost say terrible, events, in the four stages of epilepsy, meaningless contortions, dramatic display, and delirium. One might well suppose that these two varieties of fit had nothing to do with each other. There is, however, a third variety, which stands between these two extremes, common enough in this country and elsewhere; to which Sir William Gowers gave the name of "hysteroid." In this type of fit there are loss of consciousness, though this may vary in degree in different cases, rigidity of the limbs, and very frequently opisthotonos, and movements of a purposive or coördinated character, in which, however, it may be impossible to trace any one dominant idea.

It is difficult to see what single explanation will fit these three kinds of attacks, not to mention the other forms, small and great, such as hysterical petit-mal, swoons, prolonged sleep, ecstasies, and so forth. For the simple kinds of fit some simple physical explanation, such as variation in the cerebral blood-supply, might perhaps suffice, and there is a fact, rather lost sight of nowadays, which seems distinctly of the physical order, I mean the copious secretion of watery urine which may take place after a fit, to which Gilles de la Tourette added a variation in the chemical composition of the urine. The psychological explanation, on the other hand, takes for its starting-point the dramatic stage of the hystero-epileptic fit. The patient appears to be transported to some scene of her past life; it absorbs her whole consciousness, and she acts it out regardless of her present surroundings. This can be demonstrated in cases where this phase of the fit is well developed. It is reasonably argued that the same mental process is going on in the other kinds of hysterical fit, where the patient, however, does not do the acting so well. This may be so with our own countrywomen, who are not, perhaps, histrionic by nature. But it is difficult to construe in this way the meaningless movements and rigidities which are so common, especially the frequently recurring *opisthotonos*. *The particular (sexual) significance that has been* ascribed to the opisthotonos does not apply to its extreme form the "arc de cercle" or to some of the varieties of this position.

It must be mentioned, however, that serious doubts are now thrown upon the genuineness of Charcot's hystero-epileptic fits. I believe that they are not now seen in Paris, and are considered by some Parisian authorities to have been a piece of display on the part of certain well-trained patients who knew what was expected of them, and did it. There may be truth in this, but I can scarcely think it is the whole truth, for the reason that in this country, and in patients who have been subjected to no sort of suggestion, one sometimes sees attacks to which the term hystero-epileptic might quite reasonably be applied. Take first the apparent combination of epilepsy and hysteria. I remember a woman among my out-patients at the National Hospital for the Paralysed and Epileptic who while sitting in front of me had an attack which (except for the absence of tongue-biting and of micturition) most closely resembled epilepsy, and when this ceased she passed into hysterical convulsions. It may be said, perhaps, that this was hysteria following a true epileptic attack, what Sir William Gowers called post-epileptic hysteria. But in the following instance that order was reversed. the hysterical attack coming first.

A woman (Mrs. A), who had been several times in hospital, and who is no doubt a first-class hysteric. is subject *inter alia* to fits. These have been always diagnosed as hysterical, yet several observers have noticed that they look very like epilepsy. On Nov. 15th last I saw a fit of the following nature. I had just been hypnotising her, and had been pressing her rather strongly with the suggestion that she was to get rid of her symptoms. I mention this because she is rather apt to have a fit when she is too much bothered by examination or remedial suggestions. She had returned to her normal state, and was being helped into her walking jacket by her husband, when she closed her eyes, began to moan, and sank limply into his arms. He put her into a chair and then movements of the body began. I think of the nature of opisthotonos, which she often has. Thus far there was no suggestion of epilepsy; but then instead of coming round her eyes opened, rolled upwards and to the right, her face became congested, her right arm became rigid at first and then banged up and down on the side of the chair. This second stage of the attack was repeated about three times. Here, then, was a good representation of epilepsy, and indeed of unilateral epileptic convulsions, preceded by a distinct hysterical stage and, as I think, hysterical throughout.

On the strength of these and other cases I believe in the existence of hystero-epilepsy. I quite admit that I have never seen the complete and regular drama in four acts, which appears to have been the rule in the palmy days of "*la grande hystéric*" at the Salpêtrière—consisting of epilepsy, contortions or clownism, *attitudes passionnelles* or dramatic stage, and delirium, in regular sequence—but I suppose we have all seen selections from it: the common hysteroid fit represents in a mild way the clowning stage, and sometimes we witness the dramatic stage in which a past scene is re-enacted by the patient. Here is an instance.

A young sailor was sent into Queen-square Hospital with the following history. In the course of a gun drill an explosion had happened and a piece of flying metal had struck him on the head and rendered him unconscious. Ever since he had been subject to fits characterised (we were told) by unilateral convulsions. But in the hospital nothing happened until the day when he was about to leave. Then he had a fit, witnessed by the resident medical officer, in which he acted out the scene of the gun drill. He listened for the word of the commanding officer, made the proper reply, went through the manipulation of the gun, and, finally, presumably when the explosion happened, fell down on the floor.

Let us leave the subject of fits and consider some of the interparoxysmal symptoms, and in the first place those symptoms which are so common that Charcot considered them to be characteristic marks or "stigmata" of hysteria.

Anæsthesia.

The most important of them is anæsthesia, and the characters of hysterical anæsthesia are so important from the point of view of theory that I must dwell on them a short time, though doubtless they are familiar to you. Hysterical anæsthesia may be so extended and so well defined as inevitably to [illegible] a local lesion of the nervous system. What can be more natural than to suppose that a hemi-anæsthesia of the face, trunk, and limbs is due to an affection of the posterior part of the internal capsule on the opposite side? Yet in other cases where the anæsthesia is less widely spread it can be easily shown that it corresponds to no anatomical lesion. The anæsthesia which covers the area of a long glove or stocking might, it is true, be produced by a peripheral neuritis, but this explanation fails when the fingers or the feet are left out of this glove or stocking, as sometimes happens. Indeed, it is now generally admitted that hysterical anæsthesia corresponds, not to any real distribution of nerves, but to the patient's conception of her anatomy. And that the anæsthesia is conceptual (if I may use that term) can be shown in a really curious way. It can be demonstrated in some cases, where the anæsthesia appears to be absolute, that the patient really does feel after all. This fact—now known, I think, as Janet's sign—was first shown to me many years ago by Dr. R. H. Crowley, now a Member of our College, and at that time house physician to St. Bartholomew's Hospital. The demonstration was simple, you might say ludicrously simple. A girl, who had other puzzling nervous symptoms, exhibited certain areas of anæsthesia. When after closing her eyes you put a finger on one of these anæsthetic places several times, at the same time saying to her, "Say 'yes' when I touch you," she said nothing. But when you did the same thing and said to her "Say 'no' when I don't touch you," she regularly said "no" each time she was touched. Of course, shamming was suggested, but at best it must have been a very stupid sham; and I have seen this symptom in so many hysterical cases since that I feel sure it is genuine. Some patients, as might be expected, will see at once the absurdity of being asked to say "'no' when I don't touch you," and will tell you so. And even with those who reply readily enough at first, if the absurdity is brought home to them, as it may be by incautious laughter on the part of the bystanders, you will never get them to answer thus again. Still you may be able to apply the test in other ways—say as follows.

A woman was completely anæsthetic on the right half of the body and had only partial use of the right hand. I put my finger on the left part of her chest, where sensation was natural, and told her to touch with her right (semi-paralysed) hand the place that I had touched. She did so with some effort. Then after reminding her that she could use her left hand quite well, I touched the right (anæsthetic) side of her chest and told her to touch the spot with the left (non-paralysed) hand. She did so, thereby showing, of course, that she had felt the touch. I tried this a second time and she did not touch the spot, but nevertheless lifted up her hand to do so, again showing that she had felt the touch. I tried once more and this time she did nothing.

When the anæsthesia involves the muscles and deeper parts, as well as the skin, a very striking condition is produced, which is generally associated, I believe, with the name of Lasègue, though it is recorded also by Duchenne. The patient, Mrs. A, whose fit I described just now, has exhibited this condition for many years. Her left arm, and indeed all her left side, is entirely anæsthetic both as to the skin and as to the deeper parts. When she watches it she can use it moderately well; when she shuts her eyes she cannot move it at all for she is unconscious of its existence. She does not know where it is, and if you tell her to grasp it with her right hand she fumbles about to find it; and if while she is doing this you put your left hand into her right she thinks she has got hold of her own left hand. One sometimes hears of patients who after amputation of a limb retain a "phantom" of it; but here is a patient with a sound limb, who nevertheless when she shuts her eyes has not got "the ghost of a notion" of it. Nevertheless, this anæsthesia is not real, for she has been seen doing up her hair, with both her hands behind her head, where she could not watch them.

It is certainly very difficult to explain this contradictory character of hysterical anæsthesia. I do not think it has ever been described in anæsthesia dependent on organic disease. I do not know of any region of the brain, to deficient functioning of which it can be ascribed. All that one can say so far is that the patient is in a peculiar mental condition in which she feels, but does not feel that she feels. But then, again, before we explain it in a purely psychological way, there is another fact that must give us pause—namely, that in many such cases the anæsthetic parts do not bleed when they are pricked. This seems to bring us back to the brutal world of flesh and blood.

Retraction of Field of Vision.

About the second "stigma" of hysteria, concentric retraction of the field of vision, similar remarks may be made. It does not inconvenience those who are affected by it. Janet noticed patients, whose visual fields were much restricted, playing at ball in the court of the Salpêtrière without any inconvenient turning of the head to watch the ball. He also quotes the case of a boy who, having been frightened by a conflagration, had fits whenever he saw a flame. His visual field was reduced to 5°, and beyond this limit he seemed to see nothing, But when a lighted match was introduced into this blind part of the field a fit followed. Again, when a hysterical patient has quite lost the sight of one eye, it is possible by means of prisms and other apparatus known to ophthalmologists to show that the blind eye still sees.

Hysterogenic Zones.

The third "stigma" is the hysterogenic zone. This term expresses the fact that pressure upon certain parts of the body will produce, or it may be stop, a hysterical fit. I think that with regard to these "zones" we in this country are in the same position as we are with regard to hystero-epileptic fits. We do not commonly see them in a complete form. Sometimes, however, we do, and often we see them in a modified or ill-developed form. Dr. Glynn mentioned in his Bradshaw lecture the case of a boy under Mr. Luther Holden, who fell down in convulsions whenever a place on his skull was touched. I remember an out-patient at Queen-square Hospital in whom, without the least expecting it, I produced a hysterical fit by "ovarian" pressure. I ought to say inguinal pressure, because the patient was a man. I also remember a young woman with a persistent hysterical cough. Sudden pressure under the left breast produced a wince, a gasp, and a cessation of the cough. I found this out quite unexpectedly whilst looking for tender points. Now as to such tender points, I suppose everyone knows that they are very common in hysterical patients, and that they may be found without any suggestion in patients examined for the first time. They are commonest where the hysterogenic zones are commonest—i.e., in the inguinal region (so-called ovarian region), the inframammary region, the spine and to each side of it. Sometimes they are more than tender, and the patient will say that the pressure causes an oppression at the chest, a lump in the throat, or makes her "feel queer." I therefore regard these tender points as the basis upon which is developed the full-fledged hysterogenic zone.

According to psychological theories the hysterogenic zone is a subsidiary agent. That which really produces the fit is the emergence of the particular memory or idea with which the fit is invariably connected. Touching the "zone" is only a sort of signal for the explosion of the mine. This seems a reasonable explanation in some cases —for instance, where a fit can be produced by touching the site of an old injury. It is not so readily applied to the commoner cases. These tender points have a fairly regular distribution over the body. The ideas, on the other hand, upon which the fits depend must be very various in different cases. Why should touching the same stop produce such different tunes?

So much, then, for the stigmata of Charcot. It is somewhat pathetic to think that in the very land that gave them birth they have fallen from their high repute. One eminent French physician maintains, as we shall see, that the real stigmata of hysteria are mental, not bodily; another, that these bodily stigmata are due to sheer suggestion. They may, no doubt, have been over-estimated by physicians and over-elaborated perhaps by certain patients. But they exist, in a rudimentary form perhaps, in patients who never heard of their importance, so they are not, in my opinion, mere passing fashions, like ladies' ruffs or crinolines. Even at that estimate they deserve some attention as "milestones" in the history of the disease.

Contracture of Muscles.

Hysterical contracture of muscles is a very common symptom and important for our purpose, because it may be regarded from either point of view, the physical or the mental. At first sight it appears a purely physical phenomenon, and quite comparable to the contracture which occurs in connexion with disease of the pyramidal tracts. As in a transverse myelitis, so in hysteria we may witness rigidity of the lower limbs, with extension of the feet and legs and internal rotation of the thighs, so that to tell whether the case is hysterical or not we may have to appeal to other factors than the contracture itself; and even then the condition of the plantar reflex may be the only point to decide the diagnosis absolutely. It is, of course, universally held that the presence of an extensor plantar reflex indicates organic disease. And to this I should agree with one proviso—viz., that the extensor reflex should be permanent. For we know that such a reflex may occur temporarily after an epileptic fit. And I have seen it under the following circumstances:—

A boy was admitted into St. Bartholomew's Hospital. When I saw him (which was once only, on the day before his death) he had vomiting, progressive coma, and extensor plantar reflexes on both sides. I thought he had a cerebral tumour, but the post-mortem examination showed that he died from Addison's disease. Nothing abnormal was found either in the brain or the spinal cord, and a careful microscopical examination of the cord made by Dr. Farquhar Buzzard showed that it was perfectly normal.

But my point, from which I have digressed, was the close resemblance between hysterical contracture of the lower limbs and that resulting from disease of the pyramidal tracts—so close, indeed, that it has been suggested that a malnutrition of the pyramidal tracts is actually the cause of such hysterical contracture.

Nevertheless, if we consider the way in which some hysterical contractures originate, we shall be tempted to believe that in certain cases they are dependent upon mental influences. Such an origin has been suggested even for the ordinary cases of paraplegic rigidity which I have just mentioned. Most of us have seen cases where, for the relief of pain or other reasons, a splint has been put on the forearm, and after its removal the muscles have remained rigid. That this is not a mere local affection, caused by the mechanical restraint, is shown by the fact that the rigidity may spread beyond the muscles originally confined by the splint, perhaps to the whole limb. Immobility seems to have become a fixed idea. Perhaps the rarer cases of contracture of the muscles of the trunk may seem more convincing, because in them the possible influence of pyramidal tract disease can be eliminated. The examples which I will now give are from Professor Janet's book on "Neuroses and Fixed Ideas"; they illustrate his view that muscular contractures may depend upon a mental state.

1. (Vol. I., p. 304, Obs. 8.) A girl who was living in a state of much depression since the death of her only relative became the subject of a criminal assault. Her assailant, however, only succeeded in placing his hand on the right side of her abdomen. She subsequently became subject to hysterical attacks and other symptoms. On admission to the Salpêtrière the right side of the abdomen was intensely tender to touch and the abdominal muscles were rigid, particularly on the right side.

2. (Vol. II., pp. 423–428, Obs. 126.) A man had, amongst other symptoms, hysterical hemiplegia with hemianæsthesia. While this was half cured he went back to work and tried carrying parcels on his shoulders. This gave rise first to pain at the back of the neck, then to contracture of the muscles there, so that his head was constantly drawn backward, and he could not bend forward. Curiously enough, when this contracture developed the hemiplegia got well. One day he again attempted to carry a parcel, and was very much upset because he let it fall. But the result was that the contracture suddenly disappeared.

This sudden and apparently unaccountable recovery from hysterical symptoms is remarkable, though not uncommon. It is a fact that should be remembered by those who have theories as to the results of treatment.

3. (Vol. I., p. 234, Obs. 1.) Contractures of the abdominal muscles, lumbar muscles, and thigh muscles of the left side, followed by contracture of some of the neck muscles, fixing the patient in a peculiarly awkward position, resulted from the following circumstances. A girl stumbled over the body of a drunken man and ran away in a great fright. A month later hysterical fits developed, in which she had the hallucination of a man pursuing her, and tried to escape, at the same time turning her head to watch him. After each fit she assumed the following attitude—spine arched to left, body bent forward, abdomen folded on left side, head turned to left. This position gradually became permanent, owing to continuous contracture of the muscles concerned.

4. (Vol. II., pp. [illegible], Obs. [illegible].) The position of another patient was as follows: Slight flexion of the trunk to the left, owing to contracture of the left abdominal muscles—viz., rectus and obliques; slight flexion of the left thigh with adduction and inversion of the limb, which was fixed in this position by rigidity of the thigh muscles, though she could move the foot and knee. This rigidity had been preceded by clonic spasms of the muscles concerned. The actual outbreak of the hysteria was recent, and was due apparently to the loss of a sister and other troubles, but the peculiar form of it—that is, the position determined by the muscular contractures—was ascertained to correspond with the position which the patient had been in the habit of assuming years previously, under emotional circumstances of a certain kind. Later on the muscles on the left side of the abdomen, which had been rigid, became paralysed, and she fell over to the right side, almost reversing the previous position.

This last case reminds me of a girl who was under my care in St. Bartholomew's Hospital some two years ago, who could not walk without persistently bending her trunk to the left. The left lower limb was also affected, but almost in the reverse fashion to the French case which I have just quoted, for the thigh was rotated outwards and the foot dragged behind her, at the same time pointed outwards. In this way she limped along, all hunched over to the left side. It appears that she had had pains in her back, and on getting medical advice about them had been told that she had curvature of the spine. After this the peculiar attitude gradually developed. I think the idea of spinal disease must have taken great hold of her, for even in hypnosis (and she was a particularly good subject) I had much difficulty in getting her to admit that she had no such disease. The inclination of the trunk was a passable representation of lateral curvature, but I could not account for the peculiar position of the left lower limb. She eventually recovered, got married, and the last time I saw her was going out to her husband's farm in Canada.

Peculiar Features about Hysterical Contractures.

Now although it would seem that some hysterical contractures may be dependent upon a persistent or recurrent mental state or "idea," yet I doubt whether they can all be explained in this way. At any rate, contracture seems to be a symptom which would well repay careful investigation.

There are two peculiar features about hysterical contractures which I might mention here, without discussing them at length.

First, that such contractures, or, at any rate, some of them, persist during sleep. It is not always easy to observe this for oneself. There was a woman in Queen-square Hospital last year whose hand was fixed in the "obstetric position." Dr. Adie, house physician, kindly observed her at my request during her sleep, and found the position the same. Mrs. A, the patient whose fits and anæsthesia I have already described, came to me last year with her right middle finger firmly flexed into the palm. Her husband assured me that the contracture remained during her sleep. So it did during hypnotic sleep, though in this condition the finger could be easily coaxed to open. The persistence of a hysterical contracture during natural sleep is not, perhaps, what we should expect, yet it has long been known. F. C. Skey, the well-known surgeon of St. Bartholomew's Hospital, notices the fact in his lectures delivered in 1856. After commenting on the fact that chloroform anæsthesia will remove hysterical contractions of the fingers or elbow he says: "To bring this morbid state of the muscle within the influence of the mind as its cause is almost of necessity to infer the local evil to be wilful; but if it were so, the state of unconsciousness during sleep would remove it, which it does not, for the contraction is constant by night and by day."

The second point is that, when such contractures are forcibly overcome, the patient seems to suffer intense pain. The reason is not obvious. Is it due to some purely local condition of the muscles? Or is it the expression of some more general law? For some authors have noticed that pain in the head occurs when functions which hysterical patients have lost, such as memory, sensibility, or motility, are being restored in the course of treatment. Now, since permanent hysterical symptoms, such as paralysis, anæsthesia, contractures, and the like, are often ushered in by pain, it may be that in the reverse stage, from symptom to cure, pain is a stage through which the patient must pass.

Of course, in these remarks about pain and the persistence of contractures during sleep I exclude cases in which adhesions have formed about the joints—a complication which, according to Weir Mitchell, readily occurs in hysterical cases.

Vaso-motor and Nutritional Symptoms.

All the symptoms that I have mentioned as yet are common and well-known symptoms. I have dwelt on them chiefly to show that they may reasonably be interpreted from the psychological point of view. This, indeed, is the kind of interpretation which most modern theories on hysteria employ. But it will have occurred to you, no doubt, that there is another class of symptoms which are by no means easy to interpret in this way; I mean the rarer class known as vaso-motor and nutritional symptoms. Examples of this class are—fever, muscular atrophy, certain skin affections, œdema, congestions, not to mention obscure affections of secretion and excretion, as of sweat, milk, and urine. The existence of many of these has been denied, and others have been relegated to the limbo of malingering—perhaps correctly, but I doubt whether we can get rid of all of them in this way.

Affections of the Skin.

Skin affections have been described, mostly vesicular or bullous in appearance, ending in superficial ulceration; and the eagle eye of the dermatologist will pick you out lesions worthy to be dignified with the name "dermatitis neurotrophica"; but generally there hangs over these a cloud of grave suspicion that there has been some self-inflicted injury. This difficulty arose in the case of a woman who was for a long time under my care in St. Bartholomew's and Queen-square Hospitals. A very marked hysteria was in her case combined with disseminated sclerosis (the latter verified post mortem). The right loin, right side of abdomen, and right lower limb, all of which parts were anæsthetic in a hysterical sense, were covered with oval scars, the sequelæ of superficial ulceration, which were edged round with dark pigment, so as to form quite a striking picture.[2] This pigmentation I believe to have been due to arsenic, which had been freely administered before I saw her. She developed very few lesions while in my wards, so that I cannot speak with certainty as to the method of their production.

This question of self-infliction of injuries in relation to hysteria is an extremely interesting one, but can hardly be discussed in the time at my disposal.

Muscular Wasting.

Muscular wasting may be seen in hysteria, affecting (it may be) a single limb or segment of a limb, but not picking out individual muscles nor exhibiting electrical reaction of degeneration. It resembles, therefore, the muscular atrophy sometimes seen in hemiplegia rather than that of progressive muscular atrophy.

Ecchymoses.

Ecchymoses into the skin may occur, though they are uncommon. A lady, who had had a hysterical fit the night before I saw her, showed me two dark patches on her leg, and said she often "came out in bruises" after the attacks, though she was not violent in them so as to injure herself; and that once she had had a spontaneous black eye. Perhaps I may mention that I once described several cases of paroxysmal ecchymosis or œdema of the eyelids coming on without obvious cause, and that one of these cases was a hysterical girl. Another lady, whom I took to be an example of severe hysteria, told me that she had had an attack of extreme pain in the left arm, and that with this the limb had swollen and turned black, but this I did not see for myself.

Gilles de la Tourette[3] observed the following case. A girl, aged 19, had some mental upset one evening, upon which followed a storm of weeping, bad dreams all through the night, and towards morning pain on the inner side of the right leg. Next day at this spot there were an oval patch of ecchymosis (5 cm. × 3 cm.) and right hemianæsthesia most marked in the painful leg. She was confident that the mark had not been there before and that it was not the result of a blow.

I need hardly remind you that the stigmata of mediæval saints which sometimes appeared during trance or ecstasy have been interpreted, rightly or wrongly, as hysterical hæmorrhages; and the same interpretation might be given to the story of the woman who averred that certain black bruises on her thighs were caused by Satan lashing her with his iron tail, because she resisted his temptations, or to that of Alizon Device, one of the Lancashire witches, who said that a blue mark under her left breast was caused by the devil in the form of a black dog sucking there.

Œdema.

Hysterical œdema was described by Sydenham. He says:[4]—

> Just as this disease attacks all the internal parts, so also does it sometimes take possession of the external ones—namely, the muscular flesh of the jaws, shoulders, hands, legs, and ankles; sometimes causing pain, sometimes swelling. Of such swellings, that of the ankles is most remarkable, differing in two ways from that of dropsy. Dropsical swellings are, in the first place, greatest towards the evening; in the second, they retain the mark of the finger just like wet paste. In hysteria there is no such impression, and the puffiness is greatest in the morning. Generally also it is one ankle that swells. In respect, however, to size and shape, hysterical and dropsical swellings are so much alike that the patient can rarely be undeceived as to their nature.

Sydenham does not mention any change of colour in the skin, but Charcot and his school[5] described a "blue œdema" in which the surface shows a dusky congestion or cyanosis, and it would seem, according to the statements of other authors, that exceptionally the skin may even be red and hot, and that incisions have actually been made into such swellings.

[5] Gilles de la Tourette, Nouvelle Iconographie de la Salpêtrière, vol. ii., p. 265.

Hysterical œdema generally occurs in association with some other lesion, such as a contracture, a paralysis, or a painful joint. Generally it persists for some time, but sometimes it appears and disappears rapidly. The diagnosis of such paroxysmal hysterical œdema from the œdema described by Quincke (so-called angioneurotic œdema) has been discussed by Dr. F. H. Edgeworth in the *Quarterly Journal of Medicine* (Vol. II.).

The Hysterical Breast.

The hysterical breast, which in its fully developed form must be a very striking symptom, appears to be a combination of pain, œdema, and congestion, localised in this particular organ. The first reference to it was made, I believe, in 1667 by that distinguished Fellow of our College, Thomas Willis.[6] He describes the pain, tenderness, and swelling of the breast, and the associated hysterical convulsions. Later, an equally distinguished surgeon, Sir Benjamin Brodie, says in his remarks upon local hysterical affections:—

> Young women are subject to an affection of the breast corresponding to the hysterical affections of the joints, and indicated by very similar symptoms. These cases have been noticed by Sir Astley Cooper in his observations on disease of the breast. The patient complains of pain in the breast, and shrinks on pressure being made with the fingers or even on the skin being slightly pinched. Not infrequently the examination of the part produces twitches and motions of the body; yet if it can be dexterously managed while the examination is being made that the patient's attention should be otherwise engaged, not only these motions do not occur, but she may seem scarcely sensible of pain. The morbid sensibility is not confined to the breast, but extends to the axilla and down the arm. No distinct tumour is perceptible in the breast, but when the disease has been of long continuance the whole organ becomes slightly enlarged, probably in consequence of an increased determination of blood to the small vessels; yet there is no redness of the skin, and indeed the skin is even paler than natural, with a somewhat glossy appearance of its surface.

Pain and tenderness were therefore the leading feature in the cases seen by Brodie; and further, from what he says concerning the twitchings and movements produced by handling the breast, we may suspect that it was not only tender, but might have formed a hysterogenic zone. But certain other physical phenomena, missing in his description, are much in evidence in the description of Gilles de la Tourette[7] and other French authors. The nipple becomes erect, the breast swells, it may be to twice its natural size or more; the skin, which in some cases retains its normal colour, in others becomes bluish-red or bright red, and this congestion has been said actually to go on to gangrene of the skin. Féré has witnessed such swelling and redness develop in a very short space of time, apparently for no other reason than that the patient's attendant had said something that offended her. These phenomena are for the most part paroxysmal, but the pain and swelling may persist in the intervals of the attacks.

Causation of Physical Symptoms.

If I have spent your time, Sir, in speaking about these particular forms of hysteria, it is because they seem to have a particular theoretical interest. They do not fit very easily into the psychical interpretation of hysteria. We can readily understand that hysterical convulsions may be produced by the overwhelming power of some terrible memory; that pain and loss of sensation (which, after all, are but modifications of consciousness) may be produced by affections of the mind; that paralysis, or prolonged contractions, of voluntary muscles might be due to some perversion of volition. Moreover, all these things may be artificially produced by skilful hypnotism. But it is difficult to see how such outward and visible signs as œdema, congestion, or ecchymosis can be produced by purely mental agencies.

This much, however, may be said: First, that we hardly know as yet how much emotion may do towards modifying our bodily states. And emotion is certainly an important factor in hysteria. Secondly, that these same physical symptoms which I have been discussing sometimes appear and disappear in a way which seems to suggest that they depend upon the patient's state of mind. I will conclude this lecture with two cases which point this way; they shall be very briefly put.

1.[8] A girl, under the care of Professor Janet, had œdema of the wrist and dorsum of the hand. She had also anæsthesia of that side affecting both the skin and the deeper parts, so that (like the case I previously mentioned) she could only move the parts while she was looking at them. The œdema could be dispersed in the following way. While her attention was diverted to some other subject a whispered command was given to her to move her fingers. This she did unconsciously. She was then told to look at her hand, and she said in surprise, "Why, my fingers are moving. I suppose the swelling will go next." And so it did within an hour. The removal of the one symptom through some curious mental connexion effected the removal of the other.

2.[9] A case is given by Dr. Charon and Dr. Courbet relating to the mode of production of a hysterical breast. In an institution for children at Amiens was a girl, aged 13½, who was subject to hysterical convulsions and attacks of sleep. She had menstruated twice; her breasts were highly developed for her age. It so happened that the sister of the ward had an abscess of the right breast which had to be opened. Secondary hæmorrhage occurred after the operation, and caused great alarm in the establishment. The girl was particularly upset, for her own mother had died a year and a half previously from cancer of the breast, which had twice been operated upon. She lay awake for a long time in the night and in the morning felt a sharp pain in the right breast, and found it to be red and swollen. She said nothing, hoping it would pass off, but the following day, when she was having a douche, the affection was discovered. The right breast was swollen, immobile, of a uniform bluish-red colour, hot to touch, tender, but not otherwise very painful. She asked the doctor whether it was serious; he reassured her and the breast soon got well.

The authors of this paper are confident that any sort of trickery could be excluded, and they consider that it was a case of "vaso-motor affection," due to "auto-suggestion."

MEDICAL MAGISTRATE.—Dr. James Cardwell Gardner, of Amersham, has been appointed by the Lord Chancellor to the commission of the peace for the county of Bucks.

CHELSEA HOSPITAL FOR WOMEN.—The rebuilding fund of this institution is to benefit on May 5th and 6th by a sale of work, which will take place at 35, Chesham-place, S.W., by permission of the Baroness de Goldsmid. The sale will be opened on the first day by the Marchioness of Londonderry, and on the second by the Countess of Ilchester, President of the Ladies' Committee, who is also taking a stall.

be wilful; but if it were so, the state of unconsciousness during sleep would remove it, which it does not, for the contraction is constant by night and by day."

The second point is that, when such contractures are forcibly overcome, the patient seems to suffer intense pain. The reason is not obvious. Is it due to some purely local condition of the muscles? Or is it the expression of some more general law? For some authors have noticed that pain in the head occurs when functions which hysterical patients have lost, such as memory, sensibility, or motility, are being restored in the course of treatment. Now, since permanent hysterical symptoms, such as paralysis, anæsthesia, contractures, and the like, are often ushered in by pain, it may be that in the reverse stage, from symptom to cure, pain is a stage through which the patient must pass.

Of course, in these remarks about pain and the persistence of contractures during sleep I exclude cases in which adhesions have formed about the joints—a complication which, according to Weir Mitchell, readily occurs in hysterical cases.

Vaso-motor and Nutritional Symptoms.

All the symptoms that I have mentioned as yet are common and well-known symptoms. I have dwelt on them chiefly to show that they may reasonably be interpreted from the psychological point of view. This, indeed, is the kind of interpretation which most modern theories on hysteria employ. But it will have occurred to you, no doubt, that there is another class of symptoms which are by no means easy to interpret in this way; I mean the rarer class known as vaso-motor and nutritional symptoms. Examples of this class are—fever, muscular atrophy, certain skin affections, œdema, congestions, not to mention obscure affections of secretion and excretion, as of sweat, milk, and urine. The existence of many of these has been denied, and others have been relegated to the limbo of malingering—perhaps correctly, but I doubt whether we can get rid of all of them in this way.

Affections of the Skin.

Skin affections have been described, mostly vesicular or bullous in appearance, ending in superficial ulceration; and the eagle eye of the dermatologist will pick you out lesions worthy to be dignified with the name "dermatitis neurotrophica"; but generally there hangs over these a cloud of grave suspicion that there has been some *self-inflicted injury.* This difficulty arose in the case of a woman who was for a long time under my care in St. Bartholomew's and Queen-square Hospitals. A very marked hysteria was in her case combined with disseminated sclerosis (the latter verified post mortem). The right loin, right side of abdomen, and right lower limb, all of which parts were anæsthetic in a hysterical sense, were covered with oval scars, the sequelæ of superficial ulceration, which were edged round with dark pigment, so as to form quite a striking picture.[2] This pigmentation I believe to have been due to arsenic, which had been freely administered before I saw her. She developed very few lesions while in my wards, so that I cannot speak with certainty as to the method of their production.

This question of self-infliction of injuries in relation to hysteria is an extremely interesting one, but can hardly be discussed in the time at my disposal.

Muscular Wasting.

Muscular wasting may be seen in hysteria, affecting (it may be) a single limb or segment of a limb, but not picking out individual muscles nor exhibiting electrical reaction of degeneration. It resembles, therefore, the muscular atrophy sometimes seen in hemiplegia rather than that of progressive muscular atrophy.

Ecchymoses.

Ecchymoses into the skin may occur, though they are uncommon. A lady, who had had a hysterical fit the night before I saw her, showed me two dark patches on her leg, and said she often "came out in bruises" after the attacks, though she was not violent in them so as to injure herself; and that once she had had a spontaneous black eye. Perhaps I may mention that I once described several cases of paroxysmal ecchymosis or œdema of the eyelids coming on without obvious cause, and that one of these cases was a hysterical girl. Another lady, whom I took to be an example of severe hysteria, told me that she had had an attack of extreme pain in the left arm, and that with this the limb had swollen and turned black, but this I did not see for myself.

Gilles de la Tourette[3] observed the following case. A girl, aged 19, had some mental upset one evening, upon which followed a storm of weeping, bad dreams all through the night, and towards morning pain on the inner side of the right leg. Next day at this spot there were an oval patch of ecchymosis (5 cm. × 3 cm.) and right hemi-anæsthesia most marked in the painful leg. She was confident that the mark had not been there before and that it was not the result of a blow.

I need hardly remind you that the stigmata of mediæval saints which sometimes appeared during trance or ecstasy have been interpreted, rightly or wrongly, as hysterical hæmorrhages; and the same interpretation might be given to the story of the woman who averred that certain black bruises on her thighs were caused by Satan lashing her with his iron tail, because she resisted his temptations, or to that of Alizon Device, one of the Lancashire witches, who said that a blue mark under her left breast was caused by the devil in the form of a black dog sucking there.

Œdema.

Hysterical œdema was described by Sydenham. He says:[4]—

> Just as this disease attacks all the internal parts, so also does it sometimes take possession of the external ones—namely, the muscular flesh of the jaws, shoulders, hands, legs, and ankles; sometimes causing pain, sometimes swelling. Of such swellings, that of the ankles is most remarkable, differing in two ways from that of dropsy. Dropsical swellings are, in the first place, greatest towards the evening; in the second, they retain the mark of the finger just like wet paste. In hysteria there is no such impression, and the puffiness is greatest in the morning. Generally also it is one ankle that swells. In respect, however, to size and shape, hysterical and dropsical swellings are so much alike that the patient can rarely be undeceived as to their nature.

Sydenham does not mention any change of colour in the skin, but Charcot and his school[5] described a "blue œdema" in which the surface shows a dusky congestion or cyanosis, and it would seem, according to the statements of other authors, that exceptionally the skin may even be red and hot, and that incisions have actually been made into such swellings.

[4] Epistolary Dissertation to Dr. Cole, Section 29.

[5] Gilles de la Tourette, Nouvelle Iconographie de la Salpêtrière, vol. ii., p. 265.

Hysterical œdema generally occurs in association with some other lesion, such as a contracture, a paralysis, or a painful joint. Generally it persists for some time, but sometimes it appears and disappears rapidly. The diagnosis of such paroxysmal hysterical œdema from the œdema described by Quincke (so-called angioneurotic œdema) has been discussed by Dr. F. H. Edgeworth in the *Quarterly Journal of Medicine* (Vol. II.).

The Hysterical Breast.

The hysterical breast, which in its fully developed form must be a very striking symptom, appears to be a combination of pain, œdema, and congestion, localised in this particular organ. The first reference to it was made, I believe, in 1667 by that distinguished Fellow of our College, Thomas Willis.[6] He describes the pain, tenderness, and swelling of the breast, and the associated hysterical convulsions. Later, an equally distinguished surgeon, Sir Benjamin Brodie, says in his remarks upon local hysterical affections:—

> Young women are subject to an affection of the breast corresponding to the hysterical affections of the joints, and indicated by very similar symptoms. These cases have been noticed by Sir Astley Cooper in his observations on disease of the breast. The patient complains of pain in the breast, and shrinks on pressure being made with the fingers or even on the skin being slightly pinched. Not infrequently the examination of the part produces twitches and motions of the body; yet if it can be dexterously managed while the examination is being made that the patient's attention should be otherwise engaged, not only these motions do not occur, but she may seem scarcely sensible of pain. The morbid sensibility is not confined to the breast, but extends to the axilla and down the arm. No distinct tumour is perceptible in the breast, but when the disease has been of long continuance the whole organ becomes slightly enlarged, probably in consequence of an increased determination of blood to the small vessels; yet there is no redness of the skin, and indeed the skin is even paler than natural, with a somewhat glossy appearance of its surface.

Pain and tenderness were therefore the leading feature in the cases seen by Brodie; and further, from what he says concerning the twitchings and movements produced by handling the breast, we may suspect that it was not only tender, but might have formed a hysterogenic zone. But certain other physical phenomena, missing in his description, are much in evidence in the description of Gilles de la Tourette[7] and other French authors. The nipple becomes erect, the breast swells, it may be to twice its natural size or more; the skin, which in some cases retains its normal colour, in others becomes bluish-red or bright red, and this congestion has been said actually to go on to gangrene of the skin. Féré has witnessed such swelling and redness develop in a very short space of time, apparently for no other reason than that the patient's attendant had said something that offended her. These phenomena are for the most part paroxysmal, but the pain and swelling may persist in the intervals of the attacks.

Causation of Physical Symptoms.

If I have spent your time, Sir, in speaking about these particular forms of hysteria, it is because they seem to have a particular theoretical interest. They do not fit very easily into the psychical interpretation of hysteria. We can readily understand that hysterical convulsions may be produced by the overwhelming power of some terrible memory; that pain and loss of sensation (which, after all, are but modifications of consciousness) may be produced by affections of the mind; that paralysis, or prolonged contractions, of voluntary muscles might be due to some perversion of volition. Moreover, all these things may be artificially produced by skilful hypnotism. But it is difficult to see how such outward and visible signs as œdema, congestion, or ecchymosis can be produced by purely mental agencies.

This much, however, may be said: First, that we hardly know as yet how much emotion may do towards modifying our bodily states. And emotion is certainly an important factor in hysteria. Secondly, that these same physical symptoms which I have been discussing sometimes appear and disappear in a way which seems to suggest that they depend upon the patient's state of mind. I will conclude this lecture with two cases which point this way; they shall be very briefly put.

1.[8] A girl, under the care of Professor Janet, had œdema of the wrist and dorsum of the hand. She had also anæsthesia of that side affecting both the skin and the deeper parts, so that (like the case I previously mentioned) she could only move the parts while she was looking at them. The œdema could be dispersed in the following way. While her attention was diverted to some other subject a whispered command was given to her to move her fingers. This she did unconsciously. She was then told to look at her hand, and she said in surprise, "Why, my fingers are moving. I suppose the swelling will go next." And so it did within an hour. The removal of the one symptom through some curious mental connexion effected the removal of the other.

2.[9] A case is given by Dr. Charon and Dr. Courbet relating to the mode of production of a hysterical breast. In an institution for children at Amiens was a girl, aged 13½, who was subject to hysterical convulsions and attacks of sleep. She had menstruated twice; her breasts were highly developed for her age. It so happened that the sister of the ward had an abscess of the right breast which had to be opened. Secondary hæmorrhage occurred after the operation, and caused great alarm in the establishment. The girl was particularly upset, for her own mother had died a year and a half previously from cancer of the breast, which had twice been operated upon. She lay awake for a long time in the night and in the morning felt a sharp pain in the right breast, and found it to be red and swollen. She said nothing, hoping it would pass off, but the following day, when she was having a douche, the affection was discovered. The right breast was swollen, immobile, of a uniform bluish-red colour, hot to touch, tender, but not otherwise very painful. She asked the doctor whether it was serious; he reassured her and the breast soon got well.

The authors of this paper are confident that any sort of trickery could be excluded, and they consider that it was a case of "vaso-motor affection," due to "auto-suggestion."

MEDICAL MAGISTRATE.—Dr. James Cardwell Gardner, of Amersham, has been appointed by the Lord Chancellor to the commission of the peace for the county of Bucks.

CHELSEA HOSPITAL FOR WOMEN.—The rebuilding fund of this institution is to benefit on May 5th and 6th by a sale of work, which will take place at 35, Chesham-place, S.W., by permission of the Baroness de Goldsmid. The sale will be opened on the first day by the Marchioness of Londonderry, and on the second by the Countess of Ilchester, President of the Ladies' Committee, who is also taking a stall.

INTESTINAL TOXÆMIA.

WITH SPECIAL REFERENCE TO THE INDICATIONS FOR OPERATIVE TREATMENT.[1]

BY D. CHALMERS WATSON, M.D. EDIN., F.R.C.P. EDIN.,
LECTURER IN CLINICAL MEDICINE, UNIVERSITY OF EDINBURGH;
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

(*With Illustrative Plate.*)

IN his instructive opening of the discussion on intestinal toxæmia, published in the Transactions of the Edinburgh Medico-Chirurgical Society for 1913, Professor William Russell dealt at considerable length with the scientific side of the subject, time not permitting him to consider in any detail its practical aspects.[2] He dismissed the clinical aspects of the subject by stating that "there is no doubt amongst us at all as to the general proposition that the retention of alimentary excreta is deleterious and injurious to the vast majority of people." "You have," he went on to say, "isolated cases where apparently this retention of alimentary excreta has no apparent injurious effect." It is interesting to compare this statement with the definition of intestinal stasis given by Sir Arbuthnot Lane in his introduction to the discussion on alimentary toxæmia at the special meeting of Fellows of the Royal Society of Medicine in 1913.[3] Lane defines the condition as an abnormal delay in the transmission of intestinal contents through some portion or portions of the gastro-intestinal tract, resulting in the absorption into the system of a greater quantity of toxic material than the organism is able to deal with effectively by means of the organs whose function it is to eliminate it. The toxins circulate through the tissues and produce definite degenerative changes in them. Finally, the organs whose functions it is to convey, convert, and eliminate the several toxic products circulating in the blood, themselves undergo degeneration, under the influence of prolonged and progressive strain. Then the degenerative changes in the tissues progress more rapidly in proportion to the failure of the organs of elimination. It is probable that most clinicians will agree with the general propositions stated by Professor Russell, but on the all-important points of detail there may be a good deal of difference of opinion. There may be some who attach as much importance to intestinal toxæmia as I do, others who think my views fanciful and exaggerated, and yet others whose ideas on the subject are less determined, and accordingly it may be instructive if we come into closer grips with the subject in its practical aspects. In the following paper I will deal more particularly with cases of intestinal toxæmia which have proved intractable to medical treatment, and discuss the question of appropriate operative treatment.

At this date it is hardly necessary to elaborate the importance of the subject. We all know that in the past few years there have been a very large number of abdominal operations performed for chronic disease, more especially the removal of the appendix, and to a lesser extent operations on the stomach, in which the results of the operation have proved disappointing to the patient. It is too commonly assumed that the responsibility for this erroneous treatment is entirely surgical; in fairness, the responsibility has to be shared by the physician and surgeon alike. In fact, I would rather say in connexion with the class of case that I am considering that the physician is more to blame than the surgeon, as too often the surgeon is called in in these chronic cases to diagnose the condition, whereas it is really the duty of the physician to exhaust the possibilities of modern methods of investigation, and to form a provisional opinion as to the nature of the condition, and the best method of treatment by medical or by surgical means.

1. *The Pathological Basis for Intestinal Toxæmia.*

Stated shortly, this consists in the following, in various combinations:—

(*a*) *The presence of constipation.*—The existence of this is determined to some extent by the history of the patient, and also by the use of the enema and the X rays. The X rays have special value in so far as they are the only means at our disposal for locating the part of the bowel primarily affected. In this connexion it is important to bear in mind the comparative frequency with which we meet in practice cases of severe constipation in patients whose bowels move—though very imperfectly—every day.

(*b*) *An associated catarrh of the large bowel, and in aggravated cases the lower end of the small intestine.*—The existence of this is shown by excessive putrefaction in the stools with frequently marked excess of mucus, and it may be, attacks of diarrhœa, alternating with constipation. The urine is also frequently abnormal, containing catarrhal cells, white or red blood corpuscles, oxalate of lime crystals and bacteria, this condition of the urine being directly associated with and dependent upon the diseased state of the bowel.

(*c*) *Dilatation of the bowel, more especially the cæcum and colon, often associated with visceroptosis.*—These conditions are revealed by the presence of splashing on manual examination, more especially of the epigastric and cæcal regions, and by the results of X ray examination. In cases associated with marked ptosis the contour of the abdomen in the erect posture is distinctive, being flat in its upper half and prominent and bulging in its lower part. It is probable that in some of these cases a congenital weakness of the abdominal musculature is an important factor, this weakness being aggravated by defective posture and by pressure from tightly fitting corsets. In cases associated with marked ptosis the stasis is aggravated by the ptosis and conversely.

(*d*) *The presence of adhesions, membranes, pathological kinks, &c., mechanically interfering with normal intestinal movement, with resulting stasis in the large and small bowel.*—These conditions are suggested or revealed by the presence of isolated areas of tenderness on pressure, often erroneously attributed to the appendix, and by X ray examination.

2. *The Clinical Association of Normal Intestinal Functions.*

The chief indication of this is absence of any symptoms of ill-health, digestion being performed in the painless, unconscious manner characteristic of good health, and, objectively, the following.

A. *Normal stools.*—A normal stool consists largely of bacteria; it is acid, neutral, or faintly alkaline in reaction, and is free of offensive odour. Under the influence of an aperient a healthy stool acquires a more distinctly fæcal odour; in cases of intestinal toxæmia the stools may be markedly alkaline in reaction, and they are exceedingly offensive, often containing marked excess of mucus, the condition indicating abnormal putrefaction in the large bowel. When a healthy bowel is cleared out by an enema and subsequently irrigated with plain water, the returned fluid should be practically clear; in cases of severe intestinal toxæmia a very different result is obtained, the returned fluid being fæcal and foul-smelling and containing great excess of bacteria. The correction of this state of the stools is usually accompanied by the disappearance of the symptoms.

[2] THE LANCET, July 19th, 1913, p. 146.

[3] THE LANCET, March 15th, 1913, p. 755.

B. *The elimination of a normal urine.*—In this connexion attention should be particularly directed to the following points, the significance of which is, I think, not sufficiently appreciated, the different conditions referred to occurring in various combinations.

(*a*) A deficiency in the total amount of urine passed. An extreme example of this may be cited in the case of a stout lady affected with chronic rheumatism who was under my care some years ago, the total amount of urine voided in three days being just under 20 oz.

(*b*) The presence of cellular elements in the urine in marked excess of the normal. The examination of a centrifuge deposit of a normal urine obtained fresh may show the presence of two or three epithelial cells, and very occasionally a white blood corpuscle. In the cases under consideration the deposit in the centrifuge tube may be considerable, consisting of epithelial cells, white blood corpuscles, and a few red cells.

(*c*) The presence of numerous oxalate of lime crystals is a feature in not a few cases.

(*d*) The presence of bacteria in the urine; these bacteria being either voided in the urine or multiplying at an abnormal rate when voided, the latter condition indicating an unduly toxic condition of the urinary excretion.

I lay comparatively little stress on the presence or absence of indican, the one test on which reliance is laid in text-books.

The examination of the urine from these points of view requires, I think, much more attention than is commonly given to it.

In connexion with the bacteriological examination of the urine *in men* I never feel justified in passing the catheter, as this, in my opinion, is an unnecessary proceeding and not without danger. I rely on obtaining a sample of urine taken direct into a sterile *tube from the* middle of the stream with all due antiseptic precautions.

3. *X Rays. The Presence of Abnormal Intestinal Stasis.*

In recent years considerable light has been thrown on many gastro-intestinal disorders by the application of the X rays after a bismuth meal. Since Cannon first investigated the normal intestinal movement in animals by bismuth meals a vast amount of work has been carried out on intestinal movements in human subjects, notably by Hertz and others, and there is now an extensive literature on the subject. A great deal of very valuable information has been obtained, which is of value to the physician and surgeon alike in the diagnosis of various gastro-intestinal disorders, and it may safely be said that our knowledge of the great value of X rays in the diagnosis of abdominal conditions is still in its infancy. At the present time there are difficulties in regard to the completeness of the information gained by their use. These arise in the interpretation of the results, and are due largely to the absence of any standard method in connexion with the routine X ray examination. A further difficulty is the absence of sufficient data as to the range of normal limits in people who may be perfectly healthy. It would be a great advantage if radiographers adopted a standard bismuth meal and if the routine examination were made at uniformly recognised periods, as by this means we should be better able to compare the results of different observers.

We will first refer briefly to certain elementary facts which are generally accepted as established in connexion with the passage of bismuth meals.

Hertz, with a view to determining the rate of movement in the small and large bowel, examined 18 normal subjects after a bismuth meal at different intervals, in two cases every hour, in the majority of cases four times a day, and once or oftener on the day following. He found that the shadow appeared in the cæcum most frequently *four hours* after the meal, the hepatic flexure was reached from four to eight hours, the splenic flexure at 7 to 14 hours, and the junction of the descending colon with the iliac colon from 8 to 16 hours. In the pelvic colon the rate of progress was more slow. These figures represent an average.

It may be useful to follow the course of a bismuth meal as observed with the screen and radiograms. All my cases have been examined privately by Dr. W. Hope Fowler, the patients being screened immediately after the taking of the meal, and on four, five, or six occasions subsequently, at intervals ranging from 3 to 72 hours. Screen examinations were made in every instance by Dr. Fowler and myself, a very large number of photographs being taken at the same time. The meal consisted in an emulsion of 10 oz., containing 60 grm. of oxychloride of bismuth, followed by 30 grm. of the same preparation, with 4 grm. of lactose, given with 6 oz. of water. Examinations were made chiefly in the vertical position. The *shape* and the *position* of the stomach are first determined; normally the stomach hangs vertically to the left side of the middle line, and is shaped like the letter J, the lower end of it reaching from a little above to a little below the umbilicus. The *tone* of the stomach is then observed; this is revealed by the manner in which the organ grips its contents and by the rate and degree of *peristalsis*, which must be carefully observed. Immediately after food enters the stomach the organ at once commences to discharge its contents into the duodenum. The food passes into the first part of the duodenum, forming a characteristic duodenal cap, which is usually, but not invariably, revealed. After its passage into the second part of the duodenum the food may be seen passing quickly through the small intestine, but its rate of movement is usually such as to preclude a photograph being taken. In favourable cases a delicate stippling of a photographic plate may be seen, indicating the bismuth contents in the small intestine. The food is next visible in bulk when it reaches the terminal coils of the ileum and cæcum, the latter being reached in from four to six hours after the meal is taken. At the end of the sixth hour practically the whole of the food should be in the cæcum. On the following morning the bismuth contents are largely expelled, a screen examination may reveal a shadow in the rectum, pelvic colon, or iliac colon, these representing the remaining part of the bismuth meal. Our knowledge of the mechanism of the movement of the large intestine is still incomplete. The evidence available justifies the view that intestinal movements of the large bowel take place four or five times daily, as the result of which the more solid contents in the large bowel are propelled onwards over a large area.

It may safely be assumed that in cases in which the bismuth meal is not completely voided within 48 hours a pathological stasis is present, the degree and situation of this stasis being determined by the situation and amount of the bismuth contents present. Thus the presence of a residue in the rectum and pelvic colon at this time may indicate a defect in the power of the rectum to expel its contents, but this is naturally a much less severe stasis than would be indicated by the presence of the whole meal or the major part of it in the cæcum and ascending colon at the same period.

The three most common sites of stasis are the lowest part of the ileum, the cæcum and ascending colon, and the rectum. At the present time a good deal of difference of opinion exists as to the degree of ileal stasis that is met with, and as to the existence of an associated and dependent duodenal stasis. Dr. A. C. Jordan, who has directed special attention to these points, attaches great importance to ileal stasis as a common pathological condition, and claims that it is associated with marked slowing of movement in the duodenum due to the dragging of the membranous attachments at the duodeno-jejunal junction. His views are based on a large series of cases radiographed by himself and subsequently observed at operations performed by Sir Arbuthnot Lane.

Hertz, on the other hand, regards ileal stasis as largely a physiological condition, and he has further been unable to confirm Jordan's X ray findings of a dilated duodenum. A very crucial point is here involved, and it is highly important that it should be determined which view is the correct one. For my own part, while originally sharing the views advocated by Hertz, I have lately seen reason to change, and am satisfied from a more adequate first-hand knowledge of the technique adopted by Jordan that his teaching on these important points is substantially correct. I have recently seen four cases in which this duodenal stasis was present in marked degree, the X ray diagnosis being amply confirmed in one instance at which operation has been performed. The appearance of the duodenum and jejunum in one of the four cases is well shown in Fig. 1. The appearances in the figure lead me to make the suggestion that cases of diabetes should be specially investigated by means of X rays in order to determine whether this condition of the duodenum is a common one, and whether it has special significance in regard to the etiology and treatment of the disease.

4. *Clinical Conditions Induced by Intestinal Toxæmia.*[4]

Long-continued observation of many cases of chronic disease, and more especially private cases, which I have had the opportunity of investigating by the aid of modern methods of diagnosis has led me to recognise three distinct groups of conditions that arise mainly or entirely from intestinal toxæmia. These are (1) a neurasthenic group (this includes some cases at present regarded as neurotic, and also a subgroup in which the symptoms are mainly mental); (2) rheumatoid arthritis; and (3) a "dyspeptic" group. The division between these groups is somewhat arbitrary, but their separate consideration is justified on practical grounds. A few words may be said by way of elaborating these points.

1. *Neurasthenia.*—Constipation and other gastric symptoms met with in neurasthenia are, according to some writers, a result and not a cause of the neurasthenic condition. A different view is now held by many clinicians. This is well brought out in the course of a discussion on the application of surgery for the relief of neurasthenic conditions published in the Transactions of the American Surgical Association for 1910. In introducing the discussion, Blake writes as follows: "While the neurologist is apt to consider the lowered blood pressure, the disturbance of intestinal functions, the concomitant putrefaction, gas formation, and auto-intoxication as symptoms of neurasthenia there can be no doubt but that they are in a large measure causative." I fully share the view so well expressed by Blake. In the course of the last few years I have had under my care many patients the subjects of neurasthenia, some of whom have suffered from the condition for years, in which the critical analysis of the symptoms and the careful examination of the stools, the urine, and of the digestive tract by means of the X rays pointed clearly to an unhealthy state of the prima via as the primary causative factor of the disease. The patients referred to made a complete and satisfactory recovery coincident with the use of measures directed to restore the gastro-intestinal tract to a healthy condition. In some of these cases the patients had previously been regarded as neurotic, and treatment based on that diagnosis had failed to relieve the symptoms. I believe that not a few patients who are at the present time regarded as poor "neurotic" creatures are suffering from intestinal toxæmia, and the "neurotic" manifestations would largely disappear if a correct diagnosis were made and appropriate treatment applied. I have also seen in the course of the last year or two a number of advanced cases of neurasthenia associated with more or less visceroptosis which were also largely the result of a severe intestinal toxæmia. In some of these cases, which will be illustrated later, the results of medical treatment in my hands have been much less satisfactory and in regard to them the question of the advisability of operative treatment has to be considered.

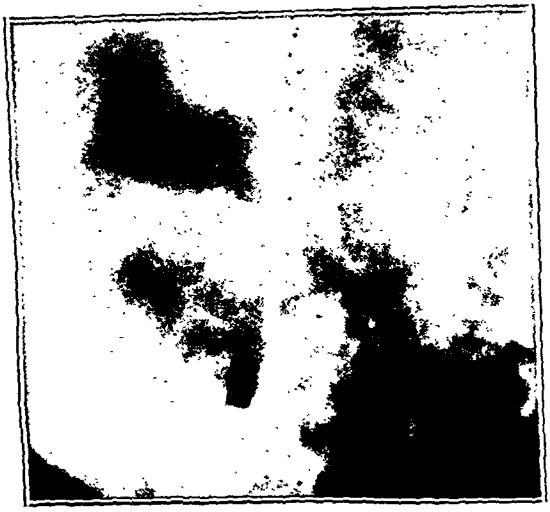
A subgroup of these cases comprises patients whose symptoms are mainly mental. Three well-marked cases of melancholia have lately been under my care, which were clearly shown to be the results of an undetected septic condition of the large bowel. These all made a satisfactory recovery when the condition was recognised and treated appropriately. In two of these cases the primary source of the infection was to be found in the septic state of the teeth and gums. It is probable that most alienists could cite similar cases. Two cases may be cited illustrating the clinical features and the difficulty in deciding the most suitable form of treatment.

CASE 1.—The patient, aged 34, complained of severe constipation and depression, of easily feeling tired, and of a "dead-weight feeling behind the sternum," having to lie down a little every day so as to get energy. The symptoms had existed for over three years and many forms of treatment had been tried. The patient was fairly well nourished

---

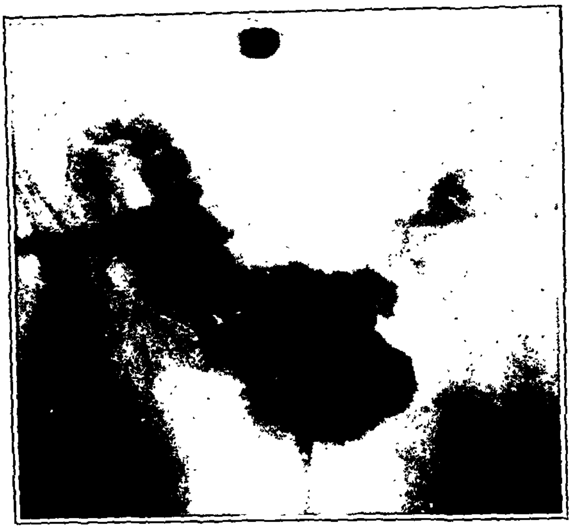
[4] The cases here referred to in detail are selected from a large number described and illustrated by series of radiograms at the meeting.

FIG. 1



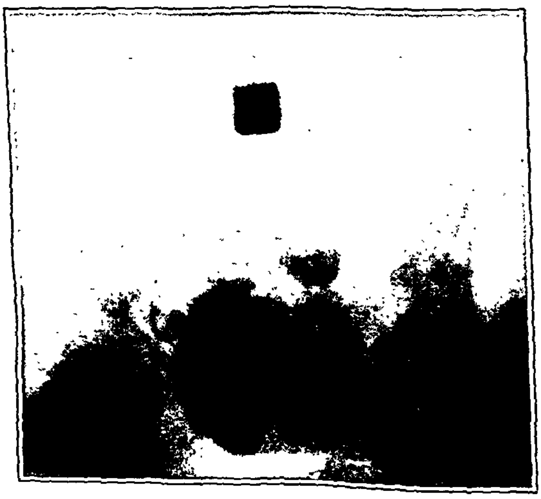
Skiagram from male diabetic, aged 45, taken 15 minutes after bismuth meal in recumbent posture. Stomach hypertonic. Bismuth contents retained in duodenum and jejunum.

FIG. 2



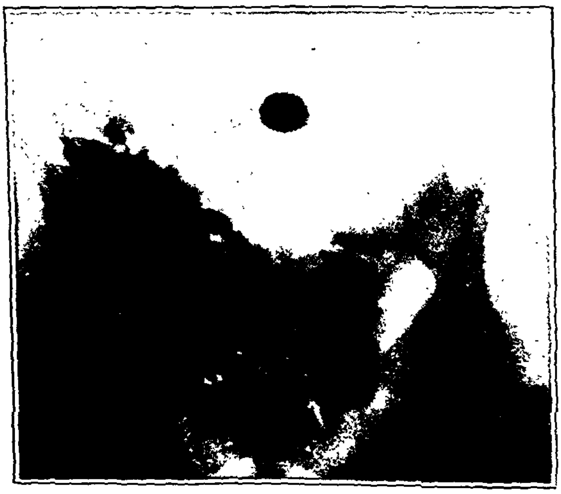
Skiagram from female patient, aged 34, taken 72 hours after bismuth meal. Note the pronounced cæcal and colon stasis.

FIG. 3



Skiagram taken 6 hours after bismuth meal. Note the food delayed in the terminal coils of the ileum indicating marked ileal stasis.

FIG. 4



Skiagram from a female patient, aged 45, taken 6 hours after a bismuth meal. Note the presence of bismuth in small amount in the stomach (slight gastric stasis); also a shadow 1 inch above the umbilicus, due to presence of food in first part of duodenum; also marked ileal stasis.

TO ILLUSTRATE DR. CHALMERS WATSON'S PAPER ON

INTESTINAL TOXÆMIA

WITH SPECIAL REFERENCE TO THE INDICATIONS FOR OPERATIVE TREATMENT

slightly anæmic, with marked splashing in the epigastric region, stools constipated, and offensive with excess of mucus. Examination after a bismuth meal showed enlarged proptosed stomach, pronounced ileal stasis after six hours, and very pronounced cæcal and colon stasis, with proptosis of the colon, the condition of things after 72 hours being as shown in Fig. 2.

Careful medical treatment, with prolonged rest, massage, including vibratory massage of the abdomen, intestinal lavage, petroleum, &c., was carried out for a couple of months, the benefit being slight and not permanent. An interesting feature of the case was that the heart hung too vertically (cardioptosis), and there was marked depression on the left half of the diaphragm, for which no adequate cause above the diaphragm could be found. As the patient and her husband are anxious that everything possible should be done to obtain relief I have now no hesitation in recommending operative treatment by a surgeon with special experience of the operation of short-circuiting with or without colectomy.

The second of these two cases illustrates the restricted success which in some instances of chronic intestinal toxæmia follows an operation specially directed to the relief of adhesions in the right lower quadrant.

CASE 2.—The patient, aged 38, unmarried, complained of troublesome symptoms of over eight years' duration. She lacked energy, became too easily tired, and had recurring attacks of indigestion associated with abdominal pain and coming on at irregular intervals without apparent cause. She had had various courses of treatment, such as rest cures, &c. She was a capable and keen woman with a pale, muddy complexion, and her muscular system was soft and flabby. There was occasional localised tenderness in the right iliac and epigastric regions, with slight splashing in the cæcal area, and the stools were very constipated and foul. This condition was very difficult to correct. The urine contained catarrhal cells, white blood corpuscles, and oxalate of lime crystals. Other sources of toxic absorption could be eliminated. The case was clearly one of intestinal stasis with toxæmia of long standing.

An attempt was made to correct the condition by medical means, with rest, vibratory massage, enemas and lavage, and general tonics. Distinct benefit followed this line of treatment, but it failed materially to improve the patient's vigour or her capacity for work, or to get rid of her indigestion. X rays were then taken, and they showed very marked ileal stasis, as seen in Fig. 3, and also general colon and cæcal stasis.

At the operation the cæcum was found to be enlarged and mobile, marked bands were found involving the terminal coils of the ileum, and the appendix was adherent, showing evidence of some old inflammation. The adhesions were liberated, the appendix was removed, and the cæcum was plicated and anchored in position.

Too short a time (four months) has elapsed since the operation to express any definite opinion as to the result of the operation; the patient is markedly better, but the incomplete relief from the indigestion and the present state of vigour lead me to think that the operation has been only partially successful, and has raised in my mind the question as to whether, in view of the clinical facts, a short circuiting operation would not have given more satisfactory results. Four months later the report is more satisfactory, the patient's general health and vigour being much better than it has been for many years previously.

2. *Rheumatoid arthritis.*—As a result of a close study of the disease I have been led to share the view now held by many clinicians as to its infective origin, the source of the infection being invariably one of the three mucous surfaces of the body. In the great majority of cases the infection comes from the gastro-intestinal tract, oral sepsis and pyorrhœa alveolaris being not infrequently primary factors in this intestinal infection; in the remaining cases the infection comes from the genito-urinary tract or the respiratory mucous membrane. With regard to the actual infective agent we have as yet no precise knowledge. For my own part I am doubtful whether the clinical pictures of rheumatoid arthritis, as we see them in their varied manifestations, are due to a single infecting agent. I think it probable that a slow infection by different organisms brings out the pathological conditions that are at present included in the term rheumatoid arthritis.

I am satisfied on this point, that the disease is essentially curable in its early stages, and that if early cases were adequately investigated and the appropriate treatment applied to the main source of infection we would soon see a profound change in the incidence of the disease in the severe forms at present met with. In the latter stages of the disease the intestinal mucous membrane, and especially the large bowel, has been seriously involved, and in some cases it is not possible to correct this by medical means. An illustrative case is here given.

CASE 3.—The patient, aged 52, married, complained of crippling pains in the left thigh, soreness and stiffness in the hands and fingers, sleeplessness, and want of vigour; duration of symptoms, over three years. She had had an attack of appendix trouble a few months before the illness set in and a good deal of digestive disturbance. Objectively there had been typical changes in the joints characteristic of rheumatoid arthritis, considerable muscular atony of the abdominal muscles with some splashing in the epigastric and cæcal regions, foul stools, urine containing many catarrhal cells, a few pus cells, and bacteriologically culture of staphylococci.

Prolonged medical treatment failed to improve the condition of the stools, and a short-circuiting operation was performed by Mr. Alexis Thomson. The patient was immensely benefited by the operation, her general health and vigour being much improved, and the soreness and pains in the joints practically subsided. Sleep is now satisfactory; she has taken no veronal for eight months, which she took regularly the previous two years. The bowels now move rather frequently. The one unfortunate result from the operation has been the tendency to diarrhœa, the bowels moving on an average four times daily.

3. *A "dyspeptic" group.*—This group, arbitrarily called a "dyspeptic" group, is characterised mainly by the symptoms of indigestion. Many cases of this group simulate very closely chronic appendicitis, duodenal ulcer, and gall-stones. A large proportion of patients who have in the past few years had an innocent appendix removed without relief of symptoms have undoubtedly been cases of intestinal toxæmia, in which the primary mischief was in the right lower quadrant of the abdomen, chiefly the cæcum and terminal coils of the ileum. It is interesting to refer to the change in opinion that has occurred in the past few years in regard to various gastro-duodenal conditions requiring surgical treatment. A few years ago ulcers in the duodenum were regarded largely as primary affections of these parts. At the present time Lane, Mayo, Moynihan, and others agree in regarding these as mainly secondary to disease either in the terminal portion of the ileum, cæcum, or appendix, often associated with adhesions and kinks in the bowel. In Lane's view the primary trouble is a stasis in the ileum and cæcum, the appendix trouble being secondary. Moynihan and others attach more attention to the appendix as the primary factor. My experience leads me to accept Lane's teaching on this point. The following is a typical example of this group.

CASE 4.—The patient, aged 45, married, had been under the care of Dr. W. L. Cullen, St. Boswells. She complained of bilious attacks with flatulence, severe headaches, a loss of weight of several years' duration. She was a poorly nourished, anæmic, tired-looking woman. In the epigastric region there was marked splashing and less marked splashing in the cæcal region, with slight pain on pressure in the latter. The stools were constipated and foul, and the urine contained many catarrhal cells and a few pus cells. Examination with the X rays showed a slightly enlarged and proptosed stomach, and retention of bismuth in the duodenum (Fig. 4), pronounced ileal stasis, as well as marked cæcal and colon stasis.

A course of medical treatment, including careful dieting, vibratory massage, enemas and lavage, was carried out for over six weeks, with very slight benefit, the symptoms returning as soon as the patient began to get about. An operation was decided on, preference being given to the short-circuiting operation.

At the operation, performed by Mr. Alexis Thomson, the stomach was found to be slightly enlarged, the pylorus was distinctly narrowed, the second and third parts of the duodenum were very markedly dilated, and numerous firm adhesions were found involving the terminal coils of the ileum, while bands connected the abdominal wall to the upper part of the ascending colon and to the first part of the descending colon, these findings amply confirming the X ray diagnosis recorded above. In view of the severity of the adhesions it was thought possible that the correction of these and anchoring the cæcum might suffice to give the patient relief. Accordingly the cicatricial bands in relation to the ileum and ascending colon were divided, the raw surfaces that resulted from this were covered with adjacent peritoneum, and the cæcum was anchored by the method of Wilms; all the raw surfaces in the affected areas were smeared with vaseline. The result of the operation, however, has not been satisfactory, it being doubtful whether the patient has derived, or is going to derive, any benefit from it. It is probable that a later short-circuiting operation or colectomy will be called for. Three months later the report is more satisfactory, the patient has benefited considerably from the operation, her condition, however, not being entirely satisfactory.

The results of operative treatment in this case, and I have seen several others with similar results, rather go to support Lane's teaching that the adhesions are more a result than a cause, and therefore treatment directed simply to the correction of adhesions will in most cases prove of little value.

General Remarks on the Operative Treatment of Advanced Cases of Intestinal Toxæmia.

Our views on the value of operative treatment in this group of cases must at present be tentative. The operative procedures requiring consideration are: (1) the treatment of any adhesions or pathological kinks which may be found on examination; (2) reducing the size of the cæcum and anchoring it *in situ*; (3) short circuiting; and (4) colectomy.

With regard to the treatment of adhesions Case 4 indicates a practical difficulty in so far as in some of these cases the benefit following the operation is slight. This must be explained either by the re-formation of fresh adhesions or by accepting Lane's view that these adhesions are a result and not a cause of the primary condition. With regard to the operation of plication of the cæcum I have had in the course of the past year a series of seven cases in private practice, in which Mr. Henry Wade has operated and reduced the size of the cæcum, anchored it to the abdominal wall, and severed any adhesions involving the terminal ileum and colon. Great benefit has followed the operation in four cases, the others being much less satisfactory. In the successful cases, the extent to which the benefit was due to the modification of the cæcum or to the correction of the adhesions is unknown. In one case in which the operation was unsuccessful the X ray examination yielded strong evidence which suggested that the stitches plicating the cæcum had given way. On the whole, I am less satisfied with the result of this operation than I was with my first two cases. There is, I believe, much to be said in favour of the wider application of the short-circuiting operation as recommended by Lane in cases that are specially selected. The number and type of cases likely to be benefited by short circuiting can only be determined after a much fuller and more extended experience of that operation in the hands of the skilled general surgeon. The operations of short circuiting and colectomy are open to grave abuse unless they are undertaken only after careful expert diagnosis of the condition and the previous application of a thorough course of medical treatment.

The general conclusions to which I draw attention are as follows.

1. The diseases under consideration are essentially medical conditions, capable of being cured by appropriate treatment if thoroughly carried out in the earlier stages; the question of surgical treatment should therefore seldom arise.
2. There are at present many advanced cases of these diseases in which prolonged medical treatment on the most modern lines produces little or no permanent benefit, and in which benefit may be looked for from appropriate surgical treatment, which effectively reduces the septic absorption from the large bowel. Examination by means of the X rays gives information of very great value in these cases; special attention should be directed to the cæcum, ileum (terminal part), and duodenum, and the results should be studied along with the other clinical findings.
3. The operation of short circuiting as recommended and performed by Lane is a simple one, but its nature is such as may readily lead to unsatisfactory results in less experienced hands.
4. Before any operation is decided upon a prolonged course of medical treatment, carried out with great attention to detail, is indicated.
5. When these medical measures have failed to relieve the operation of short circuiting, possibly combined with colectomy, partial or complete, as recommended by Lane, should be performed.

I have pleasure in expressing my indebtedness to Dr. W. Hope Fowler for the time and trouble he has taken in the investigation of the numerous cases forming the basis of my paper.

Edinburgh.

THE DRAINAGE-TUBE IN ABDOMINAL SURGERY.

BY JOSEPH E. ADAMS, M.S. LOND., F.R.C.S. ENG.,
SURGEON WITH CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL;
SURGEON, EAST LONDON HOSPITAL FOR CHILDREN.

OF recent years the value of drainage in the treatment of peritoneal infections has been very seriously called in question, and in an admirable paper published in THE LANCET[1] Cuthbert Wallace gives it as his opinion that "drainage save in true intraperitoneal abscess is useless." He speaks from an extensive experience of every type of intraperitoneal infection, and states further that the surgeon's duty has been performed when the focus of infection is removed and the abdomen closed. This view implies that the faith of the operating surgeon must be placed in the bactericidal properties of the peritoneum rather than in a temporary exit to noxious and infective fluid from the peritoneal cavity. Such an attitude is certainly strengthened by recent investigations into the bacteriology of the infected peritoneal cavity, though there are still surgeons who advocate multiple drainage in septic peritonitis, and even drainage of non-infected areas to lessen the risk of spread from an infective focus. Wallace considers that the operation in acute abdominal diseases enables the surgeon to deal with the focus of infection and relieve intra-abdominal tension, and whilst I am in the main heartily in accord with his views, I think some consideration of the pathological aspects of the case may be of value.

---

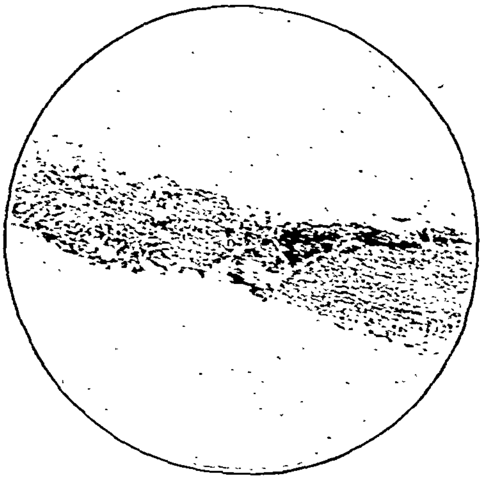
[1] THE LANCET, June 15th, 1912, p. 1603.

In a recent work on "Acute Abdominal Diseases"[2] Cassidy and I have pointed out that the resistance of the tissues of the abdominal wall is inferior to that of the peritoneum, and therefore we have advised drainage of the abdominal wall in such operations as those for the removal of an acutely inflamed appendix, and my own experience of such drainage in preference to placing a tube in the peritoneal cavity has been most encouraging. In a good many operations for acute, gangrenous, or suppurative appendicitis, both in adults and children, where a few years back a tube would have been left from the cæcum to the exterior, such tube drainage of the abdominal wall has been entirely successful and reopening of the wound has not once been called for. Wallace admits that complete closure of the abdomen in these septic cases is at times followed by virulent suppuration in the planes of the abdominal wall, and that the patient may die from such septic poisoning and not from peritonitis. Surely, such a catastrophe can be avoided by instituting free drainage of these muscular and fascial planes, and such a step appears to me to be called for in the "relief of tension," for dangerous tension is not merely that of the peritoneal cavity but of the abdominal wall also. This procedure is in keeping with the treatment of diffuse cellulitis, where suppuration is threatened, by multiple free incisions.

On the other hand, there is much truth in the saying that it is better to drain than not to drain, and it is manifestly wrong to close an acute intraperitoneal abscess; the difficulty lies in the distinction between a true abscess cavity within the peritoneum and an area infected with virulent organisms; if there is no definite space to drain it is probably better not to insert a drainage-tube. The following experimental observations throw some light on this question, but it is abundantly clear that the surgeon requires a knowledge of the bacteriology of his operations before he can truly decide where lie the uses and abuses of the drainage-tube.

To ascertain the changes induced by the presence of a rubber tube in the normal non-infected peritoneal cavity, I introduced a sterile tube into the abdomen of several rabbits; the tubes were passed into the peritoneal cavity amidst the coils of intestine and sutured at one end to the abdominal wall, which was then closed. This does not represent accurately the manner in which they are used in human beings, but the results correspond to the actual changes brought about by the presence of such tubes. I found that in a very few hours lateral openings in the tubes were closed by plugs of inflammatory exudate, and in 24 hours the whole of the tube was plastered over with newly formed fibrin, with numbers of red blood corpuscles and degenerated finely granular leucocytes. Cultures were taken before the introduction of the tubes and at the time of their removal; in all the experiments they remained sterile. The factors which determined these peritoneal changes were: (1) the presence of the foreign body, and (2) the pressure exerted by it; the latter was attributable to the fact of the tube being anchored to the abdominal wall, for in some other experimental cases where similar tubes were placed free in the peritoneal cavity little or no change occurred around them, and they could be easily withdrawn at the end of four days.

In the presence of organisms changes similar to these occur with greater rapidity, but the inflammatory processes do not stop at fibrinous closure of the tubes. One of the known effects of organisms is the liquefaction of the tissues, and therefore tubes in infected areas may be expected to yield fluid exudate. To reproduce in experimental animals the conditions obtaining in the operative treatment of human peritoneal infection is practically impossible, therefore in this direction I have investigated the effect produced by the presence of small infected cotton-wool sponges inoculated with 24-hour cultures of staphylococcus aureus. By analogy I think it is fair to infer that these results represent to some extent changes due to the pressure of foreign bodies in the presence of infection. In two cases out of seven where such infected sponges were used second cultures obtained by removing the sponge and dropping it into a broth tube showed the presence of bacilli as well as cocci; in one case the bacillus coli, and in the other the bacillus proteus, was so recovered, and in both the staphylococcus aureus was still present. The only possible source of these bacilli must have been the lumen of the gut, and the accompanying figure, which shows microscopically the formation of a fæcal fistula, readily explains the secondary infection of an embedded sponge. Macroscopically the gut over the sponge appeared thickened and inflamed, but stained sections reveal the fact that a portion of the wall is composed almost entirely of fibrin and inflammatory cells. In this connexion I may, perhaps, refer to a short note by Mr. A. E. Maylard,[3] in which he describes the way in which an



Section of intestine over sponge infected with 0·25 c.c. of broth emulsion of 24-hour agar culture of staphylococcus aureus. The sponge had remained in position for one month. Shows almost complete destruction of the intestinal wall proceeding from the serous to the mucous coat, the gap being filled up with inflammatory cells. This represents an early stage of fæcal fistula. Objective ⅔ inch.

---

[2] Baillière, Tindall, and Cox, London, 1913.

[3] THE LANCET, Feb. 28th, 1914, p. 603.

iodoform gauze plug placed in the abdomen during a gall-stone operation ulcerated its way into the bowel and caused symptoms of obstruction. This was an operation performed in the presence of infection and the passage of the plug into the lumen of the gut was clearly due to infective ulceration from its peritoneal aspect, the site of entry being healed over and protected by adhesions. It was successfully removed some 14 days after the gall-stone operation.

The consideration of the secondary infections of drained wounds would be incomplete without reference to aerial contamination, and whereas such infection may be held to be very rare during the course of an operation it is well known that any wound, abdominal or otherwise, treated by tube drainage for any length of time is apt to yield cultures of such organisms as the bacillus proteus in addition to the original causative bacterium, or this latter may be entirely outgrown by such a contaminating bacillus. It is clear, therefore, that in the case of persistently drained abdominal wounds the primary infection may have added to it organisms from without or within; the former may be derived from the external air or implanted during the dressing of the open wound, the latter may come from the lumen of the bowel as the result of pressure on the bowel wall.

From these experimental and clinical observations the following conclusions appear to me to be justified. 1. That owing to the adhesions which rapidly form around drainage-tubes their value is distinctly limited in the treatment of peritoneal infections. 2. That since the tissues of the abdominal wall possess a much lower degree of resistance than the peritoneum, drainage of the former may frequently be called for where drainage of the peritoneum is not necessary. 3. That the presence and pressure of a drainage-tube in peritonitis may determine the transudation of organisms from the lumen of the gut to the peritoneal cavity.

With regard to the last observation this secondary infection is of less serious importance than might be supposed owing to the fact that the wound area has usually been shut off by surrounding adhesions before this occurs. To prevent adhesions between drainage-tubes and adjacent structures the tube should always be rotated whenever the dressing is done, and its gradual withdrawal from the wound should be begun from the third day after operation. I have said nothing about so-called gauze drains because I believe they are more properly termed gauze dams, except when used in the form of a small wick down the lumen of a tube as a "cigarette drain," and there the capillary action of the gauze may be of value in securing the escape of thin inflammatory fluid. In the case of thick pus they more often act as a cork at the orifice of the wound than as an external drain.

As to the value of the Fowler position and the pelvic drainage-tube there is still some difference of opinion. I think there can be no doubt that the former represents the ideal attitude of the patient both for the surgeon and the nurse during the early days of abdominal convalescence, and it seems clear that the complications of subphrenic, perisplenic, and other residual abscesses have been greatly reduced in frequency by its adoption. Pelvic drainage-tubes do not appear to form adhesions quite as readily as those in other situations, and when the tube is correctly placed so that its deep end lies about half an inch from the bottom of the pelvic basin drainage even in this uphill fashion can be secured for the first few days of convalescence.

At the present time it seems totally irrational to be a slavish adherent to the policy of either always draining or never draining, but it appears to me that much of the drainage of the peritoneal cavity now practised would be better limited in scope to the abdominal wall alone.

Devonshire-place, W.

THE WILD MONKEY AS A RESERVOIR FOR THE VIRUS OF YELLOW FEVER.

BY ANDREW BALFOUR, C.M.G., M.D. EDIN.,
F.R.C.P. EDIN.,
DIRECTOR-IN-CHIEF, WELLCOME BUREAU OF SCIENTIFIC RESEARCH.

THE possibility of the wild monkey acting in certain places as a reservoir for the virus of yellow fever is a very interesting one. On my way to the West Indies I was told by a lady, Mrs. Randolph Rust, who has been long resident in Trinidad, that the old negroes there say they can always tell when there is going to be an epidemic of yellow fever in the island owing to the fact that prior to its appearance the red howler monkeys are found dying and dead in the High Woods. In view of Manson's injunction to search for a reservoir of the virus amongst some of the lower animals this negro belief struck me as curious and interesting, though naturally one did not place overmuch credence in it. Still it seems worthy of investigation, and Mr. Randolph Rust, the chief pioneer of the petroleum oil industry in Trinidad, whose land is in the south of the island at a place where monkeys abound, kindly promised to make further inquiries.

When I finally reached Port-of-Spain this question of the monkey assumed fresh interest and importance. Dr. H. L. Clare, the Surgeon-General, gave me particulars regarding the recent small outbreak of yellow fever at Brighton near the pitch lake in the south-west of Trinidad. He told me that the origin of the infection was shrouded in mystery, for there was no question of importation from the mainland or elsewhere, and, so far as could be told, there had been no mild cases of fever or illness amongst the coloured employees of the American company which is boring for oil in this vicinity. Further, the two men first attacked were employed during the day on an oil bore situated at the end of a road which had recently been cut for eight miles into the dense virgin forest. In this locality the red howlers occur, though they are only seen as a rule in the early morning. I told Dr. Clare the story about the negro belief. He had not heard of the latter, but was much interested, and agreed that it merited careful inquiry and investigation. At a later period I found several people who knew all about the negro view, but it had not struck them as deserving special attention. Mr. Rust got hold of his chief hunter, who confirmed the negro statement in every particular, and said that before the last large epidemic of yellow fever in Trinidad the red howlers were found dying and dead in large numbers. Further confirmation was forthcoming from Mr. F. W. Urich, entomologist to the Board of Agriculture, an acute and trained observer, who told me that he himself had seen the monkeys lying dead, and at the time thought they had probably perished from the effects of a protozoal blood parasite. He had not, however, specially associated this mortality with the subsequent outbreak of yellow fever.

Dr. Clare very kindly let me see the report written by Mr. A. L. George, the colonial medical officer who was sent to make inquiries as regards the Brighton outbreak. Briefly, the chief points are as follows. There were 10 cases of undoubted yellow fever, 9 amongst Americans, 1 in a Trinidadian. Three of the cases, including the first, proved fatal, and the diagnosis made by Dr. Campbell, medical officer to the Petroleum Company, was confirmed by post-mortem examination made by Dr. J. R. Dickson, who has charge of the public health laboratory at Port-of-Spain. It is only necessary to consider here such facts as may have a bearing on the monkey question.

Case 1, an American, had been five days in Trinidad. He had been in the West Indies before for one and a half years. He took ill on Nov. 21st, 1913, and the illness, as stated, terminated fatally. Case 2, an American, had been one year and seven months in Trinidad. He had never been in Trinidad prior to this period of residence. *He was also attacked on Nov. 21st, 1913,* and though he had the black vomit recovered. Cases 3, 4, and 5 were all attacked on Dec. 5th, 1913. Cases 3 and 4 were living at a bungalow in the forest, and Case 5 worked in the forest during the day, returning to Brighton at night. These three cases and those following them can all be explained by the ordinary man-mosquito infection, but the first two cannot be so easily accounted for and require some consideration. Case 1 had arrived in Trinidad from the Venezuelan mainland five days before being struck down, but Case 2, *who was taken ill almost at the same time as Case 1*, had not been out of Trinidad for one year and seven months.

Mr. George in his report expressly states: "There is not the slightest evidence that the disease was conveyed here from any outside source." His own view was that in all probability there must have been a mild unrecognised case amongst the coloured population, but he did not think this very probable, and it was admitted that the source of the outbreak was very puzzling. At my request Dr. Clare most kindly accompanied me to the oil-fields on Feb. 14th. The last case of yellow fever, and one which had terminated fatally, had occurred on Dec. 30th, 1913.

I had the pleasure of meeting Mr. George and Dr. Campbell and discussing the matter with them. It was ascertained that the two men first and well-nigh simultaneously attacked were, as already stated, working on an oil well at the end of the new asphalted motor road which had been cut into the heart of the High Woods, and which is a remarkable, indeed wonderful, engineering exploit. Further, it was found that these men spent ten hours a day on the oil-fields, going there every morning from Brighton and returning every evening. A bungalow stood in the clearing at the end of the road, and at the time of his inspection Mr. George found stegomyia fasciata vel calopus breeding there. I was informed that monkeys occurred in the woods, but there was nothing to show that they had been sick or dying. Attention had not been directed to the question. A point of interest is that there exists in these High Woods a forest species of stegomyia—namely, S. sexlineata—which closely resembles the known yellow fever carrier.

I had hoped to secure some specimens of blood from monkeys, but though I penetrated a short way into the forest, an education in itself, I saw nothing of the animals, which can only be approached when they are feeding, and then only by hunters familiar with their habits. It would, however, be interesting to examine the blood of these red howlers, both in the case of healthy and sick individuals, if the latter can be obtained. If Seidelin's paraplasma flavigenum was found to occur in their red cells it would certainly be a remarkable coincidence and perhaps go some way towards establishing the importance of the negro belief. At the same time there may be nothing in the latter.

Thanks to the kindness of Dr. Clare, to whom I am greatly indebted for much assistance when in Trinidad, of Mr. George, Dr. Campbell, and Mr. Urich, who also helped me greatly, I hope eventually to procure specimens of monkey's blood from Trinidad. In any case Dr. Clare intends to make further inquiries, so that possibly fresh light may be thrown on the question. My own time was, unfortunately, very limited, as I had a long journey before me. An attempt to get at monkeys in another part of the island ended in failure.

From Trinidad I proceeded to Ciudad Bolivar on the Orinoco, but yellow fever is rare there and, according to Dr. T. W. Parry, only imported cases occur. I was, however, told by a Canadian mining engineer that in the vicinity of Maracaibo in north-western Venezuela it had been noted that the men of the Caribbean Petroleum Company who caught yellow fever were those employed out in the bush. Accordingly, I decided to go to Maracaibo and prosecute inquiries there. On my way I visited Caracas and met Mr. Proctor, the manager of the company in Venezuela. He told me that my information was erroneous, and that the men attacked had all been resident in the town of Maracaibo. He had been much interested in the Trinidad outbreak, and informed me that, being greatly puzzled as to its origin, he had written to New York asking if monkeys were known to suffer from yellow fever as they were almost the only wild animals found near the oilfields. This is interesting as showing the view of a layman conversant with the local conditions.

On reaching Maracaibo I had the pleasure of meeting Dr. J. M. Coates Cole, who is ably upholding the prestige of British medicine in this out-of-the-way part of the world. He confirmed Mr. Proctor's statement. It seems that monkeys are not found at Maracaibo itself, but they occur along the banks of a river some 50 miles distant, and are also found abundantly in the bush on the other side of the lake, which, opposite the town, is some eight miles across. I could learn nothing about epidemics amongst monkeys there, but have set inquiries afoot and hope to obtain information through Dr. Cole, who knows the district well. Here I had an opportunity of reading the interesting paper by Dr. J. W. Scott Macfie and Dr. J. E. L. Johnston in the Proceedings of the Royal Society of Medicine, Vol. VII., No. 3, and I trust these observers will direct their attention to the monkeys of the West Coast of Africa.

The conditions in Trinidad were so interesting that, with Dr. Clare's kind permission, I wrote to Mr. H. J. Read, C.M.G., at the Colonial Office, suggesting that workers on the West Coast and elsewhere should be asked to make inquiries as regards monkey mortality, and to secure the blood of monkeys for examination.

There must, of course, be many places where monkeys can play no possible part in the etiology of yellow fever. Such a place is Curaçao, where there are no monkeys, but where yellow fever is said to be endemic and where certainly from time to time epidemics occurred, notably when warships from Holland containing non-immunes visited the island. At the same time, wild monkeys may conceivably act as a reservoir of the virus, be this Seidelin's bodies or some unknown parasite, in certain localities; and if such proved to be the case some puzzling outbreaks, like the recent one in Trinidad, would be explained. In any case it certainly seems advisable to direct attention to the possibility, and in this connexion I would cite a passage in a paper by Dr. J. Martinez Santàmaria on the Tropical Diseases of Colombia which appeared in the *Journal of Tropical Medicine and Hygiene* of April 1st, 1913. Speaking of yellow fever he says:—

> This occurs endemically and at long intervals along the Atlantic coast, Cucuta, all along the shores of the Magdalena river, and at the Muyo emerald mines. The last focus is important, as it is situated right in the middle of the country and in an uncultivated and isolated zone, with no possible communication with the Magdalena River, from which it is separated by thick and immense forests. The epidemic there is quite independent of the other focus. For the last ten years we have not had a single case in the Magdalena zone, while in Muyo three epidemics have occurred.

I am now on my way to Colombia, where I hope to obtain some more information as regards the possible association of the wild monkey, and more especially the red howler, with the occurrence of yellow fever.

Curaçao.

VACCINATION AGAINST HAY FEVER:

REPORT OF RESULTS DURING THE LAST THREE YEARS.

BY JOHN FREEMAN, M.D. OXON.,

ASSISTANT IN THE INOCULATION DEPARTMENT AND ASSISTANT BACTERIOLOGIST, ST. MARY'S HOSPITAL, LONDON.

IN 1910 and the early part of 1911 the late Mr. L. Noon worked at active immunisation against hay fever by inoculations with a pollen vaccine. He was compelled by an illness which proved fatal to stop this work in the spring of 1911 before it had been actually put to the test in a hay fever season. He published his methods of work up to date in THE LANCET of June 10th, 1911. I was able to give the first results of my colleague's method of treatment as proved by the summer of 1911 in a paper published in THE LANCET of Sept. 16th, 1911, and I now propose to give further results.

Table I., How Compiled.

In the table given below the results are shown in the case of 84 patients with English hay fever who have been inoculated with phleum pratense pollen. The first 18 in the list were inoculated before the summer of 1911; the figures in brackets correspond to the serial numbers in the report of these cases published in THE LANCET of Sept. 16th, 1911. Nos. 19 to 43 were inoculated before the summer of 1912, and Nos. 44 to 84 were inoculated before the summer of 1913. This list of 84 cases is a complete one, and therefore includes cases which received inadequate treatment.

In the case of many patients it was found convenient, after they had undergone the preliminary eye-testing and had received from me the initial inoculations, to have the treatment continued by the local practitioner. In nearly all these cases the treatment was carried out as well as possible, but there were exceptions, which are dealt with under heading No. 2 when dealing with the discrepancy in result.

The value of the symbols by which the various results have been indicated is shown underneath the table, and some further indication of the standard of marking may be gained by comparing the marks here awarded to the first 18 cases inoculated in the year 1911 with the more detailed report of these same results published in the earlier paper.

The results here recorded have in nearly all cases been derived from the patient's own report. For instance, whenever the patient has reported after the hay fever season that the doses "did not seem to make much difference," the result has been recorded by the symbol "0." In the two cases where the "—" sign has been employed there was no suggestion that the treatment had been injurious, and the "0" would, in my opinion, have been more in accordance with fact. Nevertheless, since the reports of the patients suggested that the benefits received from treatment had been a minus quantity, that result has been ruthlessly recorded.

TABLE I.

The symbols by which the results in each year are indicated have the following values: +++ = complete freedom from hay fever, or only the most insignificant symptoms. ++ = hay fever symptoms greatly diminished. + = hay fever symptoms diminished, but only to a slight degree. 0 = symptoms unchanged. — = symptoms worse. ...... = patient not inoculated in that year.

Results.

It will be seen from the table that the average of success shown in the earlier paper has been fairly well maintained in the succeeding years, both with the old cases and with the cases commenced since then. For the convenience of the reader they are here abstracted. The 84 cases have between them experienced 113 hay fever seasons after—or under—treatment. The results of these summers are as follows:—

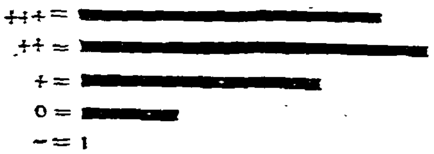
In 34 seasons (30·1 per cent.) the hay fever was completely cured or was so slight as to be insignificant.

In 39 seasons (34·5 per cent.) the hay fever was greatly diminished.

In 27 seasons (23·9 per cent.) the hay fever was admittedly diminished, but only to a slight extent.

In 13 seasons (11·5 per cent.) the hay fever was no better, and of these, two cases reported that they were worse.

This result is recorded in diagram form, thus:—



Or thus:—

The Experiential Method[1] *of Judging the Results.*

Anyone scanning Table I. and bearing in mind the reasons for its diversity of results will probably come to the conclusion that treatment is justified by statistics. They should be warned that (as is inevitable in medical statistics) such cases vary greatly in almost every important particular—e.g., the individual symptoms, the habitat of the patient, severity of the disease, amount of treatment, and the presence of complications.

But few people, and these only in rare circumstances, act on statistics. They act instead on experience, either of themselves or of others; and it seems desirable to consider what, in my experience, makes me convinced that this line of inoculation treatment is emphatically successful. When this is done, all the cases which, from their nature, approximate to the condition of crucial experiments, will come uppermost in the mind, and the other cases which, from conflicting circumstances, were very far from crucial experiments, will have relatively slight influence on the judgment in a general review of past treatment. The dramatically successful cases will affect the judgment powerfully in one direction, and the unmitigated failures will affect the judgment as powerfully in the opposite direction.

All the cases recorded in Table I. with the "+++" sign after them are satisfactory as far as results go and are all eminently quotable. As the eye runs over the cases one remembers the patients' remarks: No. 1, "Scot free"; No. 4, "farming for pleasure"—he who used to fly to the North of Scotland: No. 5, "going for walks to kick his old enemy the hay"; Nos. 7 and 8, invoking blessings and admitting the worth of the treatment, according to their different temperaments; No. 11, talking of "marvellous cures," ...... and so on; all very satisfactory and pleasant, but not so impressive as the cases where the long-continued, pitiable, and even desperate, previous condition made possible a profound change as the result of treatment, and rendered an accidental improvement almost an impossibility. For instance:—

CASE 20.—In awarding this case the "++" and "+++" signs of successful treatment no adequate idea is given of the remarkable difference between the patient's experiences during the two summers after inoculation and the summers of the previous 24 years. It was the worst case of hay fever I have ever met with. This opinion as to the severity of the case is emphatically confirmed by men of great experience of ophthalmic and nose and throat cases.[2] The inflammation of the conjunctival sacs during an attack was sometimes so intense that the conjunctiva peeled off the eyelids, leaving uncovered sore places. The continual dribbling of tears over the cheeks left them excoriated and intensely tender. The sensation of burning in the eyes was so severe that icebags were applied for long periods to give relief. Together with this the constitutional disturbance from the pollen poisoning was great, rendering the man incapable of work; for example, during hot weather in June the feet would become quite bloodless, and hot water bottles had to be applied to the extremities. For 19 years on end the patient, although absolutely dependent financially on his own personal exertions in business, was compelled to leave his work to take care of itself, and go for voyages in an ocean-going ship. Fortunately the severity of his troubles rendered him amenable to long-continued treatment, and after a very systematic inoculation carried on through the whole of the preceding winter and spring, he was able in the summer of 1912 to go on with his work in London in comfort; and in the summer of 1913 he was absolutely immune, going for bicycle excursions through hayfields during the week-ends.

CASE 32.—This case also gives no idea of the severity of the trouble from which the patient has been rendered immune. In this instance the asthma was so intense that the patient's father, who is a medical man, told me that he had been in grave fear of the death of his son from asphyxia and exhaustion. In 1913 the boy was immune except for a slight attack of conjunctival irritation one afternoon during an expedition in the country at the height of the hay fever season.

When one can call to mind such cases and others like them, one is driven to the conclusion that the method of treatment will work marvellously well on occasion. On the other hand, there are the disappointments, some of which are capable of explanation.

Explanation of Discrepancies in Result.

1. In the first place the bad result may be due to the amount of treatment the patient has received. No. 43 will serve as a case in point. In 1912 the patient did not come for treatment till the middle of June, and then only received two inoculations—result "0"; whereas in 1913 he came in March and received eight doses—result "++." It is for this reason that cases treated by me at the Inoculation Department, St. Mary's Hospital, have on the whole given rather better results than private patients because hospital patients will submit to treatment at Christmas or even earlier, if they are advised to do so, while private patients will for various reasons seldom submit to this. On the other hand, it must be admitted that some people demand a "cure" within a week or ten days, and

[1] A. E. Wright on the Pharmaco-therapy of Pneumococcus Infections, and the Methods by which such Therapeutic Problems ought to be Investigated, THE LANCET, vol. ii., 1912, pp. 1633, 1701.

[2] Dr. W. A. Brailey, Mr. Charters J. Symonds, and Dr. H. L. Gregory.

somewhat to the surprise of the inoculator get what they ask for.

2. One reason for a bad result will disappear when the principles of vaccine therapy are better known—e.g., a practitioner who was continuing the treatment of a patient in the country had been supplied with several correct doses, and a letter was received from the patient saying that, "wishing to be in the best possible form at a flower show, the doctor gave me two doses at once." The result was naturally disappointing. (Case No. 47.)

3. Bacterial catarrhs of the air-passages may be an addition to, or a complication of, these pollen poisonings which constitute hay fever. When these two diseases are present together they seem to form a vicious circle; the bacterial catarrh seems to make the patient more prone to pollen poisoning, and the sodden condition of the mucous membranes produced by hay fever is an open invitation to any bacterial infection. No. 2 is a case in point. The patient suffered from a chronic nasal infection and sinusitis, and indeed had been for long inoculated against this with a streptococcus and diphtheroid vaccine. In addition he was found to have hay fever by the eye-reaction test; pollen vaccine failed to give him relief. Such cases are difficult to treat, and it is difficult to say which symptoms are due to the bacterial infection and which to the pollen poisoning. It is for this reason that many men have believed that hay fever is itself a microbic infection, and claim (no doubt with justice) that they have rendered great benefit with a bacterial vaccine. Vaccines made from Friedländer's B. pneumoniæ, streptococci, M. catarrhalis and pneumococci have all been used against hay fever and, it is alleged, with success. Those who would ascribe to bacteria more than a secondary rôle in hay fever should note that most hay fever patients have little or no bacterial infection of the nose passages during the summer, while the bacterial catarrhs which do occur in hay fever patients are not all due to one particular organism.

4. No. 8 is hardly a success, but the circumstances are unusual. It is the case of a university professor who lives practically in a botanical garden full of exotic plants. The inoculations work fairly well so long as he is away from home, but when he returns he collapses. The causal agent of hay fever in Europe is grass pollen and the professor may be considered to be, botanically speaking, outside Europe.

These four points account for a considerable proportion of failures or partial failures in Table I., but after all the explanations there remains an inexplicable residue. No. 29, perhaps, had too little treatment, No. 51, however, should have had sufficient, and No. 55 (a hospital case) had very systematic treatment, and yet seemed to receive no benefit. In the present state of our knowledge such cases may be credited, if we so please, to the idiosyncrasies of the patients.

In reviewing the cases which have shown these differences of result one gains the following impressions:—

Patients with marked constitutional disturbances, including asthma, do better than patients with slight and local symptoms.

Patients with an inherited tendency do better than people without such tendency.

Age makes no difference to the benefit derived from treatment.

How Long Does the Effect of Treatment Last?

Patients naturally wish to know whether they must be inoculated every year, or whether one successful series of inoculations will last for more than one year, or possibly last for ever. Three hay fever seasons have passed since the inoculations were first commenced.

In Table II. the results during the years in which the patients were inoculated is given on the left-hand side of the table, while the after-effects in the years during which the patients were not inoculated is given on the right-hand side of the table. It will be seen that where a patient has been inoculated for one year with complete success he has in the next year complete, or *almost complete*, immunity, but that in the third year he has only slight immunity left. Where patients have been successfully inoculated for two years they have, as might be expected, complete immunity during the third year, and time will show how long this complete immunity *will last*. Where patients have been only partially immunised for one or two years, little if any immunity is carried over to the year during which they have ceased the inoculations.

TABLE II.

Case.	During treatment.		No treatment.	
	1911	1912	1912	1913
4	+++	+++		+++
14	++	+++		++
16	+++		+++	+
1	+++		+++	+
15	+++		++	
23		+++		++
13	++	++		+
17	+	++		0
10	++	+		0
12	++		++	0
3	++		+	0
7	++		+	0
36		++		+
24		++		0
31		++		0
33		++		0
6	+		0	0
34		+		0
37		+		0
42		+		0

The cases have the same numbers as in Table I., but are here arranged according to the completeness of the immunisation. The symbols have the same value in both tables.

Conclusion.

Hay fever treatment by active immunisation with a pollen vaccine, whether judged by statistics or by the experiential method, has succeeded, and the immunity thus acquired seems to last for one year at least after treatment has been discontinued.

Devonshire-place, W.

MUNICIPAL HONOURS FOR MEDICAL MEN.—At the last meeting of the Glastonbury town council Dr. Maurice John Doidge was elected an alderman for the borough.—At the recent election for members of the Stonehouse urban district council Mr. William Edward Manderson Corbett was returned at the head of the poll.—Mr. Alfred Probus Trinder has been elected a member of the Wadebridge urban district council.—Mr. George Lestock Thornton has been elected chairman of the Exmouth urban council.

THE USE OF OMNOPON-SCOPOLAMINE COMBINED WITH LOCAL ANÆSTHESIA IN OPHTHALMIC SURGERY.

BY A. MAITLAND RAMSAY, M.D. GLASG., F.R.F.P.S. GLASG.,

OPHTHALMIC SURGEON TO THE ROYAL INFIRMARY, GLASGOW; AND LECTURER ON DISEASES OF THE EYE IN THE UNIVERSITY OF GLASGOW.

Omnopon or pantopon—the name by which it is known on the continent of Europe—was introduced by Professor Sahli, director of the medical clinic at Berne. He was anxious to obtain the full therapeutic effect of opium by hypodermic injection, and asked Hoffmann-La Roche and Co. to produce a preparation of opium in which the total alkaloids would be in a soluble form and free from all inert and irritating matters. In opium the natural alkaloids exist in the form of almost insoluble meconates, but after a series of experiments a preparation was produced in which they were present as readily soluble hydrochlorides. Omnopon forms a light brown powder, five times the strength of opium, and contains the alkaloids in the same proportion as in the crude drug. It is usually prescribed as a 2 per cent. aqueous solution to which 25 per cent. of glycerine is added as a preservative. It may be given by the mouth, but in most instances it is more convenient to administer it by hypodermic injection. It is supplied for that purpose in sterile ampoules, each containing 1 c.c. of the 2 per cent. aqueous solution of the drug. It was soon discovered that the good qualities of omnopon were greatly enhanced by combining it with scopolamine, and omnopon-scopolamine is now preferred by many to the better known morphine-scopolamine preparation. The average dose for an adult is ⅔ grain of omnopon and 1/150 grain scopolamine.

An article in THE LANCET of Sept. 2nd, 1911, by Mr. H. M. W. Gray first directed my attention to omnopon. In that paper Mr. Gray advocates its use as an adjuvant to local anæsthesia, and gives an up-to-date bibliography of the use of the drug in medical practice. I began to use omnopon in my operative work in November, 1911, and with increased experience of its value have come to rely upon it more and more when operating upon patients to whom in former years I would have given a general anæsthetic. It is true that since the introduction of cocaine, chloroform and ether are used much less frequently in operations upon the eye. The use of cocaine by itself, however, does little to allay a patient's nervousness and restlessness. Local anæsthesia may be perfect, but the mind of the patient is not at ease. He is alert and apprehensive, and in consequence has difficulty in keeping himself under proper control. The use of omnopon, however, acts as a sedative to the brain, makes the patient feel calm and self-possessed, and thereby helps the surgeon to perform the operation easily and satisfactorily.

On the whole, omnopon acts best in elderly patients, and may be safely given in cases where the administration of a general anæsthetic might be attended by considerable anxiety and danger. I have used it only when operating upon adults, but Mr. Gray states that "in juveniles above 13 the effect has been quite satisfactory." To young subjects he gives half the dose usually prescribed for an adult.

If a patient is to have omnopon he should be prepared as he would be for a general anæsthetic. An hour and a half before the time fixed for the operation the contents of a 1 c.c. sterile ampoule are injected into the muscles of the gluteal region. The patient ought to be in bed during the interval of waiting, and if the room be darkened and care be taken that he is not disturbed by noise he will usually rest quietly or sleep until it is time to carry him to the operating table. He ought never to be allowed to walk or to be roused more than can be avoided. If a single dose is not enough to induce sleep, an additional half dose is injected an hour after the first. This extra dose is rarely necessary; it can, however, be administered without risk, and ought always to be given if the patient be nervous and excitable. It is essential that the patient be thoroughly under the influence of the drug. He wakens up while he is being carried to the operation room, answers questions, and may even engage in conversation, but if the dose of omnopon be sufficient he is quite free from excitement or from any feeling of nervous dread or apprehensiveness. If he be let alone for a few minutes after he is placed on the operating table he usually falls asleep, but he wakens at once when he is spoken to, and he is ready to assist the operator by voluntarily turning his eye in whatever direction may be necessary.

The local anæsthetic employed is a 2 per cent. aqueous solution of cocaine hydrochloride, which is dropped three times into the conjunctival sac at an interval of five minutes between each instillation. If the anæsthetic is to be injected beneath the conjunctiva or under the skin a 2 per cent. solution of novocaine, to each ounce of which 30 minims of adrenalin chloride (1 in 1000) have been added, is employed.

I have used omnopon-scopolamine as an adjuvant to local anæsthesia in the following operations upon the eyeball and its appendages—cataract extraction, iridectomy in iritis and in acute glaucoma, irido-sclerectomy in chronic glaucoma, plastic operations on the eyelids, extirpation of the lacrymal sac, and enucleation of the globe. In these different operations omnopon-scopolamine acted least satisfactorily in extraction of senile cataract, because it made the patient so drowsy that the eyeball constantly tended to roll upwards, and thereby hindered the delivery of the lens. No general sedative is as a rule necessary in operations for cataract, but the patients to whom I gave omnopon-scopolamine were abnormally nervous and restless. Although the use of the drug in no way facilitated the actual operation, the after effects were all that could be desired, for the patients fell asleep almost immediately after being taken to bed, and slept soundly for several hours. Its analgesic and soporific effects are most helpful to restless patients during the first hours following an operation, for the drug possesses few disadvantages; no period of excitement precedes sleep, and neither pulse nor respiration is markedly affected.

The pulse-rate may for a short time be slightly accelerated, but it very soon returns to normal, while the respirations, although slow, are regular and deep and never stertorous. The face sometimes is flushed, but there is no lividity. The patient sleeps soundly and quietly, but is easily roused. He sometimes complains of thirst, and readily takes any liquid offered to him. While awake he talks quite coherently and intelligently, but on the following morning he has no recollection of what he has said, and is often very much surprised when he is told that the operation has been performed. Sickness and vomiting occur very rarely, there is no complaint of headache or of giddiness, and on the morning after the operation the patient is usually free from any effect of the drug.

Before iridectomy or before advancement or tenotomy of the recti muscles local anæsthesia may be rendered perfect if, after cocaine has been instilled into the conjunctival sac, a few drops of novocaine-adrenalin solution be injected beneath the conjunctiva at the site of the operation wound. This method has the additional advantage in irido-sclerectomy that it greatly facilitates the formation of a large flap of conjunctiva.

In plastic operations on the eyelids infiltration anæsthesia is employed. After the skin has been disinfected the novocaine-adrenalin solution must be injected freely and allowed to act for 20 minutes before the operation is begun. At the end of that time the skin over the area affected by the anæsthetising fluid is distinctly blanched owing to constriction of the blood-vessels, and consequently hæmorrhage during the operation is rarely troublesome. If the local anæsthesia be carried out properly, and a sufficient dose of omnopon-scopolamine has been administered, the patient sleeps quietly, and unless he is spoken to gives no indication that he is aware of anything being done to him.

In extirpation of the lacrymal sac, if the local anæsthesia is to be satisfactory, great care must be taken to follow the technique recommended for the injection of the novocaine-adrenalin solution. The skin of the side of the nose and of the eyelids should be disinfected by painting it with a 3 per cent. tincture of iodine. The needle of the hypodermic syringe, which has been carefully sterilised, is then inserted along the line of the primary incision, and as it is being withdrawn the novocaine-adrenalin solution is injected slowly into the cellular tissue around the track of the needle. The lacrymal sac is filled with the anæsthetising fluid by the inferior canaliculus, and after waiting a few minutes deep injections are made, one above the dome of the sac and another below the internal tarsal ligament. The hypodermic needle must be inserted deeply until its point strikes the bone and the fluid is forced into the tissues around and behind the tear sac. Twenty minutes should elapse before the operation is begun, because all that time is necessary for the novocaine-adrenalin to exercise its full effect on the nerves and blood-vessels. The infiltration method of anæsthesia has been objected to on the ground that the œdema of the tissues obscures landmarks and alters the natural relationship of structures, so that the operation is rendered more difficult. Dr. E. Seidl[1] has recently proposed a method of "conduction anæsthesia" in extirpation of the lacrymal sac, and claims for it that both anæsthesia and ischæmia are complete and that no œdema is present in the tissues to be operated on. It consists in applying novocaine-adrenalin solution to the nerves supplying the tear sac and superjacent skin at some distance from the actual field of operation. The technique is simple and easily followed, and in the few cases in which I have employed Seidl's method the results have been quite satisfactory. It has, however, the drawback that in some cases considerable ecchymosis of the upper lid and slight exophthalmos follow the injection.

For enucleation of the eyeball the majority of surgeons would prefer to have the patient under the influence of a general anæsthetic, but the operation can be performed painlessly and with entire absence of shock if omnopon-scopolamine be employed as an adjuvant to local anæsthesia. There need be no hesitation in employing this method in any case where a general anæsthetic is contraindicated or where a patient is unwilling to take ether or chloroform. After the conjunctival sac is anæsthetised by the instillation of cocaine the novocaine-adrenalin solution is injected beneath the conjunctiva over the insertion of the four recti muscles. A Siegrist's needle is then passed deeply into the orbit and the anæsthetising fluid injected into the tissues behind the eyeball. I usually insert the needle at each quadrant of the globe between the recti muscles and inject about 5 minims of the solution at each puncture. After waiting for 20 minutes the eyeball can be enucleated without pain and with the minimum of hæmorrhage.

The success of these operations undoubtedly depends in large measure on the perfection of the local anæsthesia, but the addition of omnopon-scopolamine adds greatly to the comfort both of the patient and of the operator. The former is in great measure oblivious to what is going on, and the latter is not disturbed during the operation by restlessness and nervous apprehensiveness on the part of the patient.

Glasgow.

EXTRAPERITONEAL URETERO-LITHOTOMY THROUGH A MEDIAN SUPRAPUBIC INCISION.

BY GORDON WHITEHEAD, M.B., CH.B. VICT.,
LATE RESIDENT SURGICAL OFFICER, ANCOATS HOSPITAL, MANCHESTER.

With Remarks by JOHN MORLEY, F.R.C.S. Eng.,
SURGEON TO THE HOSPITAL.

THE following case, which was under the care of Mr. John Morley in Ancoats Hospital, Manchester, may be of interest to readers of THE LANCET.

The patient, a youth aged 20, was lying in bed convalescent after an operation for radical cure of a right inguinal hernia performed ten days before, when he was seized with a sudden attack of pain in the left loin, shooting down into the groin. The previous history was as follows. At the age of 7 he had acute retention of urine from a stone impacted in the penile urethra. This was removed by external urethrotomy. In his eleventh year, after left renal colic and hæmaturia, a stone was removed from the bladder by a suprapubic incision. Another vesical calculus was removed at the age of 15. When 16 years old a radical cure of left inguinal hernia was performed.

On admission to hospital on Oct. 1st, 1913, for radical cure of his right inguinal hernia, he made no complaint of left lumbar pain, but after the present attack he admitted that he had suffered from two or three similar attacks during the last few weeks before admission. The attack of renal colic that occurred whilst he was under observation was of short duration. The urine, examined shortly afterwards, was as follows: reaction acid;

---

[1] Graefe's Archiv für Ophthalmologie, 87 Band, Heft 1.

specific gravity 1022; trace of albumin; no blood; no deposit. An X ray examination showed a calculus of the size of a sparrow's egg impacted in the lower end of the left ureter.

An operation was performed on Oct. 24th under spinal anæsthesia (stovaine-glucose Billon). Cystoscopic examination having revealed no abnormality of the left ureteric orifice, the bladder was opened by a median suprapubic incision. The calculus could be palpated near the ureteric orifice by a finger in the bladder, but this procedure caused it to slip upwards in the ureter, and transvesical removal was plainly impossible. By free retraction of the left rectus and extraperitoneal dissection the left ureter, which was dilated and thickened, was exposed at the point where it crosses the pelvic brim, at the bifurcation of the common iliac artery. A sling of stout pedicle silk was passed round it with an aneurysm needle and held with artery forceps. With one finger in the bladder and one outside, the stone was then pushed up from the depths of the pelvis to the pelvic brim. Here it was held against the silk sling, whilst a second loop of silk was passed round the ureter below it. Thus steadied and exposed, the smooth oval stone was removed through a longitudinal incision. The opening in the ureter was closed with fine catgut. A long thin tube was put down to the incision in the ureter and brought out at the lower end of the suprapubic wound. The bladder was then sutured completely with catgut and the suprapubic wound closed up to the drainage-tube. A soft rubber catheter was tied in for 48 hours, at the end of which both catheter and drainage-tube were removed. Except that a few drops of urine leaked from the ureter on the third day, recovery was uneventful and the wound healed by first intention.

Remarks by MR. MORLEY.—The bladder was opened by a median suprapubic incision in this case because it was suspected that the stone would be found encysted close to the ureteric orifice and would be most easily removed by the transvesical route. This method did not prove feasible. The excellent access to the pelvic ureter obtained by extraperitoneal dissection through the same median incision suggests that in similar cases the median incision might be used and the stone removed from the ureter, after pushing it back to the pelvic brim, without opening the bladder. The recognised methods for removal of stones from the lower end of the male ureter are: (1) Extraperitoneal (or combined intra- and extra-peritoneal, a finger being inserted into the peritoneum to control the stone) through an oblique incision in the loin; (2) transperitoneal; (3) transvesical; and (4) injection of oil by the ureteric catheter followed if necessary by removal with the operating cystoscope. The first method gives good access but involves more damage to the belly wall than the median incision; the second is less satisfactory on account of the danger of leaking of urine into the peritoneum; the third is only possible where the stone is encysted close to the ureteric orifice; and the fourth can only be done with very small stones that are visible on cystoscopic examination of the ureteric meatus. One important proviso must be made in recommending the median incision. Complete muscular relaxation must be obtained, and this can only be done by the use of spinal anæsthesia. In this case the ease with which the flaccid rectus could be retracted to the side was most remarkable.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

The Need of Research in Ante-natal Pathology.

A MEETING of this section was held on April 2nd, Dr. W. S. A. GRIFFITH being in the chair.

A discussion was opened by Dr. AMAND ROUTH on this subject, who said that progress in ante-natal pathology since Sir William Priestley's Lumleian lectures on the Pathology of Intra-uterine Death in 1887[1] had been small, except as regards syphilis, which was now better understood because of recent discoveries. The present ante-natal mortality in England and Wales, according to his estimate of 2·2 stillbirths and 8·8 abortions to 100 live births, was about 100,000 annually. He pointed out the essential difference in the physiological and pathological activity of the embryo and the fœtus. Diseases affecting the former caused anomalies of structure, while the same diseases produced abnormalities in the latter by interference with function. In either case ante-natal death might follow, leading to abortion or premature labour. Dr. Routh next discussed some of the more general causes of ante-natal death together with the problems dependent thereon. He dwelt in particular upon ante-natal syphilis and ante-natal tuberculosis. With regard to syphilis, he described the clinical evidences of this disease in the fœtus and placenta. According to a number of observers the spirochæta pallida was present in from 70 to 80 per cent. of macerated stillborn fœtuses. With regard to tuberculosis, since the tubercle bacillus had not yet been demonstrated in the early embryo, it was considered that the ovum was rarely infected by this agent, and that placental tuberculosis also was rare. Dr. Routh then discussed paternal infection of the ovum and the question whether tuberculosis led to structural anomalies in the early ovum. He emphasised the divergence of existing views upon the whole subject of ante-natal pathology, the absence of exact knowledge, and the need for research in all directions. Compulsory registration of stillbirths and confidential notification of causes of death in particular were necessary for the improvement of statistics.

Dr. J. W. BALLANTYNE (whose paper was read by Dr. T. W. EDEN) said that he had in 1887 published his first paper on general dropsy of the fœtus, and in 1899 had lectured on ante-natal pathology and teratology in the University of Edinburgh. Since then he had been led to investigate morbid states of gestation as they affected the mother. He considered that there were two large regions to be explored. Firstly, the physiology and pathology of pregnancy such as were met with in the pre-maternity wards of any hospital. Secondly, there was that of the physiology and pathology of each of the three periods of ante-natal life so far as the new being was concerned, the periods of germinal, embryonic, and fœtal activity. Lastly, there was the consideration of the placenta (or decidua) both in health and disease. Without a serious study of ante-natal pathology there could be no marked improvement in race health, and race health was the watchword of the present day; eugenics was attempting to solve it, but eugenics without obstetrics and ante-natal pathology and hygiene would have but small success.

Dr. F. W. MOTT said that he had for years made a personal investigation of the family history of a number of cases of juvenile general paralysis with a view to showing that this disease is invariably caused by syphilis. Dr. Mott found that both sexes are affected in equal proportion, unlike that of acquired syphilis in which males exceed females in the proportion of 4 or 5 to 1. In inquiring into family histories a number of interesting facts were obtained which related to ante-natal death, and which were considered under different groups. The usual history obtained was that the mother, after one or more miscarriages followed by abortions and stillbirths, had one or more children who generally died in early infancy from convulsions, hydrocephalus, or meningitis; later a child survived, and at puberty or early adolescence developed general paralysis. The histories of 34 syphilitic mothers gave 175 conceptions. These were made up of 104 premature births or deaths in early infancy, 41 diseased in some serious form or other, 30 were apparently healthy, but many of these may have suffered later, and certainly a considerable percentage of these apparently healthy children would have given a positive Wassermann reaction. In four instances the mothers were affected after marriage and after each had given birth to healthy children. It was of interest to note what followed in respect to conceptions before and after the mothers had been infected. Taken together there were 15 conceptions before infection resulting in the birth and rearing of 15 healthy children. After infection there were 22 conceptions; of these, 13 were abortions, still-births, and children dying in early infancy; of the remaining 9 there were 5 seriously diseased, and there was no absolute proof that the remaining 4 were healthy. Next came the question of spermatic infection and transmission of the disease to the offspring without infection of the mother. Here Dr. Mott agreed with Neisser that the mother of a syphilitic child was herself syphilitic, although she might not show signs in such cases because the disease was latent. It had been pointed out by Plaut regarding the Wassermann reaction in paralytic men and women and their offspring that 37 per cent. of the spouses of such paralytic men and paralytic women gave a positive Wassermann reaction. Finally, Dr. Mott referred to the examination of a series of still-born and premature-born fœtuses received from the Shoreditch Infirmary; out of 22 cases examined spirochætæ were found in 11. The author referred to the method he used of demonstrating the spirochætæ in the brains of persons dying from general paralysis and of syphilitic fœtuses, showing the organism to be the same in the two conditions.

---

[1] THE LANCET, vol. i., 1887, pp. 759, 814, and 855.

Dr. **DARWALL-SMITH** gave the results of an investigation he had made on the influence of the nutrition of the mother on the infant and on her labour and puerperium. His chief conclusions were that a state of bad nutrition of the mother at the time of labour increased the percentage of dead births and premature births, also the post-natal infantile mortality. It decreased the average weight of the full-term child at birth. On the other hand, a state of good nutrition of the mother increased the supply of milk and also the average weight of the child at birth.

Dr. **LEITH MURRAY** (Liverpool) confined his remarks mainly to the bearings of pregnancy to immunity production. He contended that the main part of the research to be done on ante-natal pathology, particularly that on the immunology of pregnancy, was work for experts, more especially in serology and biochemistry, and that the National Insurance Research Fund could help here.

Dr. **ERIC PRITCHARD** spoke on the question of tuberculous disease in the newly born infant, and pointed out how difficult this was to demonstrate, and must be still more so in the unborn baby.

Dr. **CAMAC WILKINSON** said that he had definitely taught for the past 15 years that the father could not convey infection to the ovum unless the mother was first infected. He contended that the infection of syphilis was similar to that of tuberculosis, and there appeared to him irresistible evidence that tuberculosis could not be conveyed by the paternal element.

Dr. **EARDLEY HOLLAND** and Dr. **A. W. RUSSELL** also spoke.

Dr. **ROUTH**, in reply, alluded to Dr. Newsholme's welcome statement that the Local Government Board had been so impressed with the value of this research that they had been able to make a grant to Dr. Holland and Dr. P. B. Ridge to enable them to embark upon the necessary laboratory research. Dr. A. W. Russell (Glasgow) had also stated that a layman had given £3000 to equip a laboratory in the Glasgow Maternity Hospital. The section also had heard the suggestion of Dr. Murray that the National Insurance Research Fund, which apparently amounted to about £57,000 a year, and which under Lord Moulton's chairmanship had already done so much for research in tuberculosis, should be used also for research in ante-natal pathology. He hoped this might be practicable, and this discussion would help forward any such scheme. As regarded the scientific results of the discussion, two or three things were evident. First, that very little was certain as regarded ante-natal disease, either with regard to relative incidence, source or method of infection, prophylaxis, or treatment. Taking syphilis, for instance, the very existence of paternal infection of the ovum was denied by such an authority as Dr. Mott. Dr. Routh saw no particular reason why paternal infection and fertilisation of the ovum should not be simultaneous, nor did he see why the fertilised ovum freshly implanted upon the uterine mucosa could not be easily infected by the male parent's infected semen. Tuberculosis, again, could not be as yet proved to infect the embryo or fœtus in utero except in relatively a few cases, but he thought it very likely that tubercle did infect the early embryo, and if so its effect upon the delicate cellular three-layered blastoderm would be considerable, and could easily cause dystrophic abnormalities which would lead to early and perhaps unrecognisable abortions. Research must decide these points, as well as the curious fact that in syphilis spirochætæ were but rarely found in the early embryo, and were yet found in abundance in the fœtus. He hoped the discussion would greatly stimulate extended research.

MANCHESTER MEDICAL SOCIETY.

The Bacteriology of Milk in Relation to Infant Feeding and to the Treatment of Alimentary Disease.

A MEETING of this society was held on April 1st, Dr. **ARCHIBALD DONALD** being in the chair.

Dr. **RALPH VINCENT** opened a discussion on the Bacteriology of Milk in Relation to Infant Feeding and to the Treatment of Alimentary Disease. He grouped the organisms according to the conditions determining their growth in milk. 1. Bacteria producing lactic acid but not producing gas. This group was represented by the streptococcus lacticus and the bacillus lacticus. The streptococcus lacticus was the typical organism growing in pure milk at 38° C. At a later stage, when the acidity had become too great for the streptococcus, the bacillus lacticus appeared, for this organism was exceptionally tolerant of acid. 2. Bacteria producing lactic acid, carbon dioxide, and alcohol. This group embraced the whole of the colon organisms, and included the bacillus acidi lactici (Hueppe), bacterium acidi lactici (Esten), bacillus lactis aerogenes (Escherich), and the bacillus coli communis. When pure milk was incubated the growth of the organisms belonging to this group was inhibited by the growth of the organisms belonging to the first group. When milk, however, was grossly contaminated by colon organisms these might acquire dominance, and in such cases the curdled milk showed evidence of gas production. 3. Bacteria growing in "pasteurised" milk—that is, milk that had been subjected to a temperature between 65° and 100° C. The bacillus putrificus and the bacillus lactis aerogenes were examples of this group, and their products were of a highly irritant and dangerous character. 4. Bacteria growing in milk after it had been raised to 100° C. owing to the fact that their spores had not been destroyed. These organisms were found in milk that had been boiled or "sterilised" and in condensed milk. The group embraced a large number of organisms, the chief representatives being the bacillus subtilis, the bacillus mesentericus, and the bacillus mesentericus vulgatus. When they developed in the intestines extremely powerful poisons of an alkaloidal character were created, and the adsorption of these poisons produced profound coma and death. The contents of the small intestine were normally acid owing to the formation of lactic acid from lactose by the lactic bacteria. Were it not for this acid condition putrefactive processes would occur. In the soil the conditions were reversed, for putrefaction was the essential process by means of which dead organic matter was decomposed and rendered available for the vegetable kingdom. The lecturer discussed the methods of bacteriological examinations of intestinal dejecta employed at the Infants Hospital, and drew especial attention to the pathological conditions induced by improper diet. When the infant was deprived of the lactic organisms naturally present in milk the colon organisms became proteolytic and grave illness resulted. All his observations had gone to show the extreme importance of the milk for infants being given in its raw condition. He believed that improper feeding with cooked food encouraged the development of tuberculosis, and that the boiling of milk played an important part in the production of diseased conditions in infancy and childhood. Dr. Vincent concluded with a lantern demonstration of numerous photomicrographs illustrating the organisms found in various pathological conditions of the alimentary tract.

Dr. NATHAN RAW said that he did not think it was sufficiently well known that pure milk was sterile, and that the lactic organisms were non-pathogenic. Dr. Vincent's remarks applied to the conditions obtaining at the Infants Hospital, which enjoyed rather exceptional benefits, but in such towns as Liverpool and Manchester it was surely safer to pasteurise the milk before giving it to children. His own observations had brought him to the conclusion that there was a very real danger in such towns of infants contracting tuberculous disease from untreated milk; he would like to ask Dr. Vincent if he did not think that bovine tubercle bacilli were capable of infecting children.

Dr. C. P. LAPAGE said that he would like to have heard Dr. Vincent's opinion on dried milk. He had come to the conclusion that in slum districts it was safer for the milk to be pasteurised than to be given to infants untreated.

Dr. VINCENT, in his reply, said that he was astonished to hear Dr. Raw speak of a "sterile" milk. Neither human milk nor cow's milk was sterile. Collected with the greatest care both milks after about eight hours' incubation at blood temperature normally showed a profuse growth of the *streptococcus lacticus*. The bacillus aerogenes capsulatus could always be found in cow's milk provided a sufficient quantity of cow's milk was taken. He did not think that the "pasteurisation" recommended by Dr. Raw could be relied upon to destroy tubercle bacilli. He based his statement in regard to cooked milk and tuberculosis simply upon practical experience, not only of himself but of many others. He could not establish any relationship between the consumption of raw milk and the incidence of tuberculosis. On the contrary, he found that children fed on boiled or condensed milk were much more prone to the disease, especiallly in its more serious forms. He found it difficult to understand the attitude generally adopted by medical men who favoured the boiling of milk, for they were uniformly silent on the subject of boiling the butter, a concentrated milk product always prepared from raw milk. Practically all the infants attending the out-patient department of the Infants Hospital were fed on raw milk which the mothers obtained from the ordinary milk shops. The infants did extraordinarily well, and the work there afforded no justification for the advocacy of boiled milk. He was inclined to agree with Dr. Lapage with regard to dried milk. If a child had to be fed on a cooked food, then dried milk was better than boiled milk.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held at the Royal Army Medical College on April 9th, Colonel Bruce M. Skinner, M.V.O., A.M.S., the President, being in the chair. Major Josiah Oldfield, R.A.M.C. (T.) read a paper entitled "The Scope of the Field Ambulance as a Training School." He said that the modern tendency in business enterprise was towards single control and single portal training with subsequent specialisation in place of sporadic, varied, and uncorrelated methods. He submitted that the methods which had secured success by promoting harmony, economy, and capacity for expansion in modern great businesses were worthy of consideration if as perfect an organisation as possible was wanted for the medical administration of the Territorial Force. In order to secure harmonious working and complete understanding by every officer and man of his duties and responsibilities, and to provide thorough and standardised training, the field ambulance should be the one training school for the officers and men responsible for the health of the troops. At present the regimental medical officer was inadequately trained and was not required to attend camp at all—in fact, if the battalion to which he was attached was at full strength he was only allowed to go to camp every alternate year, whereas the field ambulance medical officer was required to attend camp once in every three years, and pressure was brought to bear on him to make him attend every second year. The regimental medical officer was too isolated, whereas the field ambulance medical officer was not so. The speaker emphasised this point because he thought that camp was the one absolutely essential method of training officers as well as men for their duties in peace and war. He laid stress on the standardisation of working, and contended that the only way that this could be obtained was by having the field ambulance as the one school for training. After general training then specialisation could be taken up in some particular branch. At present the position of the regimental medical officer was not unmistakably clear with regard to the question of command, and friction might arise. The problem of command would be solved if it were the duty of the officer commanding the field ambulance to post an officer to each battalion in camp. Such officer would be responsible to his officer commanding for the due discharge of his duties; he would mess with his field ambulance, and would be an integral part of the unit. By means of this constant interchange of duties every officer would have a knowledge of working of the whole medical machinery with the Territorial Force.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 17th, Dr. W. Langdon Brown, a Vice-President, being in the chair.—Mr. R. M. Vick showed: 1. A plump baby of 5 months with a supposed Palsy of the Right Arm. Periostitis of the right humerus and other bones was detected by X rays. It was the thirteenth child. There had been iritis in previous children, miscarriages, and early deaths. The Wassermann reaction was positive. The child was rapidly improving under the use of mercurial ointment. 2. A married woman of 40, who had had pain in the left breast for a year. There was a large hard mass in the upper and outer breast quadrant; the skin was adherent to it, as also the tissues below. The axillary and *supraclavicular* glands were involved.—Dr. W. Langdon Brown showed: 1. A man of 58 with marked Anæmia and Anorexia; he had vomited in September, 1913. There was some leucopænia; no tumour could be felt. The test meal showed an absence of free hydrochloric acid, the X rays some irregularity of the stomach's outline, and the benzidine-peroxide test of the stools blood. From these facts malignant disease of the stomach was diagnosed. 2. A man of 44, the subject of glycosuria for four years and thirst and wasting for three years. He was on von Noorden's diet, was benefited, but not free from glycosuria. His pupils were unequal and knee-jerks absent. 3. A woman of 47 the subject of glycosuria for seven years. Similar diet removed the sugar from her urine on some days. Dr. Brown also read notes of a case of a young girl admitted for Multiple Arthritis, who developed peri- and endo-carditis, pneumonia, blood in the stools, incontinence of urine and fæces, and oscillating fever. After sensitised vaccines were administered she rapidly improved. Recovery was uneventful. She left hospital with only an apical cardiac bruit.—Dr. Leonard Williams showed a woman of 51, with a healthy family, who complained of dorsal backache. The bismuth feed was seen to reach a dark patch at the level of the aortic arch readily, then to go up and down. Aneurysm was thought less probable than a neoplasm through the breadth of the hindrance and the absence of usual aneurysmal signs.—Mr. Henry Curtis showed a specimen of Primary Squamous Epithelioma of the end of the nose removed with three-quarters of an inch of surrounding skin. A thorough removal of salivary, submaxillary, and lymphatic glands and cervical lymphatic glands was effected and of the skin in the lymph track by cutting down to the jaw. Four and a half months later the man is still well.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Devon and Exeter Hospital on April 3rd, Mr. Ransom Pickard, the President, being in the chair.—Mr. F. W. Langridge read a paper to open a discussion on What is Bright's Disease? He initiated his remarks by quoting from various standard books on medicine, and showing the confusion which existed in the nosology of renal affections. He then dwelt for some length on the pathological changes and the concomitant symptoms relative to the large white, small white, and granular kidney respectively, and said that whatever opinion might be held when the marked differences, pathological and clinical, were considered between the desquamative and the cirrhotic types of nephritis it was hard to disagree with Rose Bradford when he refused to classify them together under the one heading of "Bright's disease." The amyloid kidney, which was also included by some authors, had little clinically or pathologically to warrant its classification under Bright's disease. In these circumstances, where there was so much uncertainty of opinion, how was the unfortunate general practitioner, or the still more unfortunate candidate for examination, to state an opinion? Mr. Langridge considered that a time had arrived when except in conversation with patients and their friends the term "Bright's disease" should be abandoned as being inaccurate and therefore unscientific. He suggested in substitution a nomenclature based on the pathological finding—viz., the acute tubal nephritis, and the two varieties of chronic nephritis, parenchymatous or tubal, the small white kidney being considered with the granular form, as clinically and in treatment they were inseparable. As regards mixed forms where it was impossible to relegate to any of these classes, Mr. Langridge bade those present to follow the advice of one of Mark Twain's celebrities who said, "When in doubt speak the truth."—In the discussion which followed, Dr. Henry Davy said that at one time every form of albuminuria was considered as Bright's disease; with increased knowledge had come more differentiation. In the future he considered that a further classification would be made based upon the bacteriological finding. Scarlet fever played an important part in the etiology. It might yet be found that the small cirrhotic kidney was the outcome of bacterial invasion. He quoted a case of albuminuria where the cause had undoubtedly been a short streptococcus and where urotropine had proved beneficial. Again, amyloid disease was of bacterial origin.—Dr. William Gordon said that the subject of the paper opened up two lines of thought: (1) nomenclature and (2) diagnosis. Mr. Langridge had concerned himself chiefly with the nomenclature, whilst Dr. Davy had followed both lines. Speaking for himself, Dr. Gordon had discarded the name Bright's disease, but in his earliest associations with medicine he had understood it to mean a diffuse non-suppurative disease of the kidney. Dr. Gordon then discussed chronic renal disease and the possibility of an inflammatory origin as suggested by gout, lead and alcohol being undoubted causes. He considered, however, that it was an academic question best left to the pathologists. The speaker then dwelt on those cases of albuminuria occurring at 40 and upwards and remaining without any apparent evil influence on the life of the patient. Should such be labelled Bright's disease? He offered an affection at one pole only of one kidney as a possible solution of the symptoms manifested in these cases. He advised that the term Bright's disease should not be used unless asked for, and pointed to the field of investigation open in the matter of permanent and transient albuminuria.—The President said that Bright had included all cases of albuminuria under his own nomenclature at a discussion. Speaking from his own experience at the Eye Infirmary, he (the President) had noted that the retinal changes often appeared before the albuminuria. In pregnancy the albumin might never appear although retinal changes were present. With regard to the germ theory of nephritis, even if they accepted it they must still "go back further" to complete the pathology. With regard to arterio-sclerotic cases, he had found changes in the retinal veins as complete as in the arteries. He had found small patches in the region of the yellow spot which were distinctive of Bright's disease as opposed to atheroma.—Dr. R. V. Solly excluded cases of recognised bacterial origin from the category of Bright's disease, and he pointed out the fallacy of interpreting a bacilluria as necessarily meaning the presence of renal disease simply because excretion from the kidney had been proved. He then discussed the experiments of Rose Bradford, and considered that the internal secretion theory had little for its support. He considered that Bright's disease was due to a toxin produced under various conditions, and that they must go further back than the bacteria themselves.—Dr. Raglan Thomas alluded to cases where hæmaturia and finally albumin were directly related to the passage of crystals of uric acid.—Mr. A. C. Roper said that formerly the presence of albuminuric retinitis was a death warrant to the patient, but now it was found that 50 per cent. of a certain class recover. In illustration he read notes on a case demanding a severe surgical operation for fibromyoma where the patient had previously been observed at the Eye Infirmary to be suffering from albuminuria and retinitis. She had stood operation well and was making an excellent recovery.—Dr. F. A. Roper discussed the question of transient albuminuria and its control by calcium lactate.—Mr. Langridge replied.

MANCHESTER PATHOLOGICAL SOCIETY.—A meeting of this society was held on April 8th, Dr. A. Brown presiding.—Dr. C. P. Lapage read a paper on the Clinical Pathology of the Cerebro-spinal Fluid in Meningitis in Children. He described the chemical, physical, and microscopical findings in the different forms of meningitis, laying great emphasis on the value of performing lumbar puncture early and of using specific serum as soon as possible. More than 70 per cent. of his cases were tuberculous. He described the technique of mounting the film which usually formed in this variety of meningitis. If the cerebro-spinal fluid from a case that was obviously one of meningitis remained clear and retained its power of reducing Fehling's solution the disease was probably tuberculous.—Dr. D. E. Core read a paper on Subarachnoid Hæmorrhage. He shortly discussed the anatomy of the arachnoid mater, pointing out the structural differences that existed in this membrane: (1) at the base; and (2) on the lateral aspects of the cerebral hemispheres. The morbid anatomy of diffuse subarachnoid hæmorrhage was dealt with, the appearances varying according as to whether the bleeding began at the base of the brain or upon the lateral convexity. The importance of syphilis as a causal agency in the production of the condition was mentioned, and the absence of any traumatic history in the cases he had personally observed. The symptomatology—profound coma, epileptiform tremors, and final flaccid paralysis in the limbs first convulsed—was described. The rapidly fatal nature of the condition was referred to.—Dr. D. H. Paul read a paper on Disseminated Softenings in the Spinal Cord in a case of Pancreatic Cancer. These small foci of softening were not commonly found in cords taken from cancer cases—they had been found in other diseases of a toxic nature and in caisson disease. If sufficient time elapsed before death they caused secondary degeneration and were characterised by marked swelling of the axis-cylinders, absence of inflammatory reaction, and neuroglial proliferation, but the vessels showed a high degree of hyaline degeneration. Dr. Paul did not regard these foci as myelitic, but rather of the nature of ischæmic softenings.—Mr. R. Ollerenshaw read a short paper on Sacro-coccygeal Cysts.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on April 16th, Dr. E. W. Hope, the President, being in the chair.—Dr. W. Permewan read notes of a case of Thrombosis of the Lateral Sinus following acute suppurative otitis, with remarks on ligature of the internal jugular vein. He described the clinical history of the case and the surgical and therapeutic treatment adopted. The important points were ligature of the vein and clearing out the clot. A phylacogen had been used with, he thought, beneficial effect.—Mr. Colin G. Campbell related a somewhat similar case.—Mr. Hugh E. Jones agreed to removal of the clot, but he was inclined in acute conditions to do a small rather than a large operation, and suggested that infective processes frequently limited themselves.—Dr. W. Sanderson spoke of his result after ligature of the vein.—Dr. C. A. Adair Dighton quoted some statistics and said he had not lost a case since he began to ligature the vein.—Mr. G. C. E. Simpson read a note upon Some Operations for Femoral Hernia and related nine cases upon which he had operated by the inguinal route. The advantages were several: high access to the neck of the sac, free exposure of the fasciæ round the ring, and the excellent closure of the ring obtainable. Four of the cases were strangulated; in other two of the series there was a hernia of the bladder.—Mr. R. W. Murray, as an advocate of the saccular theory of hernia, did not attach much importance to suture of fasciæ, but considered the access to the neck of the sac by this route an advantage.—Mr. T. C. Litler Jones said that the sac did not always disappear if left, as he had found a lipomatous mass some years after operation.—Mr. T. R. W. Armour always used this route for two main reasons: that the whole sac could be removed and the top instead of the bottom end of the crural canal could be closed.—Dr. R. W. MacKenna read a medico-literary causerie upon Some Reflections on the Act of Death.—The President, Dr J. R. Logan, and Dr. E. T. Davies also spoke, the last named giving a personal experience.

Reviews and Notices of Books.

Ulcer of the Stomach.

By CHARLES BOLTON, M.D., D.Sc. Lond., F.R.C.P. Lond., Director of Pathological Studies and Research, and Lecturer in General Pathology in University College Hospital Medical School; Physician (with Charge of Out-patients) to University College Hospital. London: Edward Arnold. 1913. Pp. 396. Price 15*s.* net.

ULCER of the stomach is a common affection, and although its symptomatology and treatment are well recognised and understood the etiology and pathology have given rise to much discussion, and there is still a want of unanimity in regard to those points. In the work now before us an instructive account is given of the general pathology of the disease, special attention is drawn to experimental research, and a considerable amount of valuable original investigation is recorded. We are entirely in accord with Dr. Bolton's views as to the importance of blending a study of morbid anatomy and clinical medicine with experimental pathology. It is true, as he remarks, that certain pathological problems can be studied exclusively in the laboratory, but these are merely parts of the whole, and eventually must be correlated with the facts obtained through a study of the patient.

In discussing the pathology of gastric ulcer three conditions are described—the acute ulcer, the transitional forms, and the chronic ulcer—and the characteristic features of each are pointed out. A number of excellent reproductions of photographs of morbid specimens adds to the value of the letter-press. The remarks on the formation of acute gastric ulcer demand careful attention. Amongst the causes which may give rise to the initial lesion that precedes the formation of the acute ulcer, bacterial infection of the body is said to be a frequent factor. The infection may be general, and either acute or chronic, or it may be a purely local one. The organism causing the lesion may be a specific organism of the disease, or it may be secondarily introduced. Dr. Bolton proceeds to remark that although it has not yet been demonstrated in the human subject that a poison of metabolic origin is capable of bringing about necrosis of the gastric mucous membrane, his experiments with gastrotoxin have demonstrated the possibility of such an occurrence. Gastrotoxin belongs to a group of immune substances known as cytotoxins, and he showed in 1904 that such a substance could be produced by immunising an animal with the gastric cells of another animal. He further says that the initial change in the formation of the acute ulcer is neither thrombosis, embolism, nor hæmorrhage, and that the actual necrosis is caused by the gastric juice acting upon a cell in some way changed by the poison, which has been brought to it by the blood, so that it is rendered susceptible to the action of the gastric juice; the process is, consequently, one of self-digestion. He therefore considers the principle established that a poison of metabolic origin which circulates in the blood may be capable of initiating self-digestion, and the actual death of the cell is not a necessary antecedent to such digestion.

The observations on hæmorrhage into the mucous membrane are also interesting. The most important and the commonest cause Dr. Bolton believes to be bacterial invasion, which may bring about the event in one of two ways—either by a direct action of the bacterial poisons upon the capillary wall, or by giving rise to vascular occlusion and hæmorrhagic infarction. In the latter case necrosis of the tissue is always present; in the former case necrosis may or may not be present.

Evidence is then quoted to support the view that the chronic gastric ulcer is derived from the acute variety, and the objections which have been advanced against this opinion are criticised, but Dr. Bolton is strongly of opinion that the chronic ulcer does arise as an acute lesion. The symptomatology of acute and chronic ulcers is well and lucidly given, and the diagnosis and prognosis of these affections are discussed at length. The value of hæmatemesis as a diagnostic symptom of gastric ulcer is carefully considered, for during recent years much discussion has centred round this symptom in the differential diagnosis of gastric ulcer. As is well known, profuse hæmorrhage may occur from the mucous membrane of the stomach apart from gastric ulceration, and the situations in which this may occur and the condition known as "gastrostaxis" are duly commented on. The remarks on the clinical investigation of hæmatemesis are also worthy of note.

In the section of the work dealing with treatment the methods which should be adopted in cases of acute gastric ulcer are first described. Rectal feeding is, of course, fully discussed, but Dr. Bolton is strongly of opinion that hæmorrhage from the stomach is practically the only complication of gastric ulcer which necessitates this method of feeding, and also that mouth feeding should be started at the earliest possible moment. In describing the treatment of chronic gastric ulcer he first expresses his own views, and remarks that in this form of the disease rectal feeding is very rarely needed apart from the occurrence of hæmorrhage. We doubt, however, whether the majority of physicians would concur in this opinion. He attaches great value to the administration of alkalies.

We have perused this volume with much interest, and can recommend it as a valuable and instructive treatise.

A Handbook of Practical Treatment by Many Writers.

Edited by JOHN H. MUSSER, M.D., LL.D., Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia, and A. O. J. KELLY, A.M., M.D., late Assistant Professor of Medicine in the University of Pennsylvania, Philadelphia. Vol. III. London and Philadelphia: W. B. Saunders Company. Pp. 1095. Price 75*s.* per set of 3 vols.

THE third and concluding volume of this important work is concerned with the treatment of constitutional diseases such as diabetes, obesity, scurvy, gout, arthritis deformans, and diseases of the respiratory, digestive, urinary, and nervous systems. There are also short articles on diseases of the muscles and on mental disorders.

The treatment of diabetes mellitus is discussed in a scientific and practical article by Dr. Theodore C. Janeway, of New York, who puts as the chief aims of treatment the improvement of the carbohydrate tolerance and the prevention of hyperglycæmia. At the same time he recognises the dangers of acidosis, and points out that in severe cases the need for combating acidosis may be paramount and the prevention of hyperglycæmia subordinate. He also emphasises the importance of maintaining nutrition. Dr. Janeway describes a practical method of determining carbohydrate tolerance. For purposes of treatment the cases are divided into mild, severe, and intermediate, and the measures discussed comprise diet, hygiene and exercise, treatment at health resorts, and drugs. Considerations of diet are dealt with on scientific principles, and some valuable diet tables are given. Owing to the facts that patients with severe diabetes manufacture sugar from protein and that they are usually more intolerant of the carbohydrate so derived than of that taken preformed in the diet, Dr. Janeway lays great stress upon the regulation of the protein intake in these cases. Dr. Thomas B. Futcher, in discussing diabetes insipidus, divides the cases into three groups—viz., those in which there is an organic basis in the central nervous system, very often syphilitic; those in which a functional neurosis coexists; and those which he describes as the renal type. Dr. Albion Walter Hewlett contributes a series of short articles on obesity, inanition, scurvy and infantile scurvy, rickets and osteomalacia. That devoted to obesity gives an interesting account of the principles of treatment of that condition, together with some useful diet lists.

Dr. Futcher contributes articles on gout, lithæmia, and chronic articular rheumatism. Diseases of the respiratory system are considered at length, Dr. Charles W. Richardson contributing a practical article on the treatment of diseases of the nose and throat, while Dr. John H. Musser has dealt with diseases of the bronchial tubes, asthma, hay fever, and pulmonary emphysema. Dr. James E. Talley discusses the treatment of hæmoptysis, pulmonary œdema, and other disorders of the circulation in the lungs, such as embolism and congestion. In every instance the treatment is discussed critically, and valuable practical suggestions are often given. We may mention the article on the treatment of hæmoptysis as an especially interesting and useful contribution to the subject. The treatment of tracheal and bronchial obstructions is described by Dr. Chevalier Jackson; that of broncho-pneumonia, pneumonoconiosis, abscess and gangrene of the lung by Dr. Henry Jackson. Other articles deal with speech defects, diseases of the pleura, and the surgery of infectious diseases of the lung and pleura. In the last of these, which was written by Dr. Samuel Robinson, an interesting account of the use of artificial pneumothorax as a means of treatment is given. A noteworthy article is that by Dr. Isaac A. Abt on diseases of the respiratory system in children.

Diseases of the digestive system are dealt with in an equally practical and instructive manner in a series of important articles, among which we may mention that on diseases of the stomach by Dr. Bertram W. Sippy. A useful summary of the indications for surgical treatment in cases of gastric ulcer is given, as well as detailed instructions in regard to the dietetic and medicinal treatment of that condition. The surgery of the œsophagus is described by Dr. Charles H. Mayo, that of the stomach and duodenum by Dr. William J. Mayo, while the surgery of the liver and gall bladder is discussed by Dr. Maynard Ladd. Diseases of the pancreas are considered by Dr. James M. Anders, and Sir Berkeley G. A. Moynihan contributes a note on the special circumstances in operations upon the pancreas.

The treatment of diseases of the urinary system is dealt with from the medical point of view by the late Dr. Egbert Le Fevre, and from the surgical standpoint by Dr. Guy L. Hunner.

The treatment of diseases of the nervous system is considered by Dr. William G. Spiller, Dr. Charles H. Frazier, Dr. E. W. Taylor, Dr. John Homans, Dr. F. X. Dercum, and Dr. C. H. Moffitt. Dr. Dercum contributes a useful article upon the treatment of the co-called functional nervous disorders. Dr. Moffitt discusses vaso-motor and trophic disorders, and also diseases of the muscles.

The concluding article deals with the treatment of diseases of the mind, and is written by Dr. James Hendrie Lloyd.

This volume worthily maintains the standard set by its predecessors, and the system of treatment as a whole is one we can commend to our readers as a sound practical work of reference.

A Synopsis of Surgery.

By ERNEST W. HEY GROVES, M.S. Lond., F.R.C.S. Eng., Surgeon to the Bristol General Hospital, Lecturer on Surgery at Bristol University. Fourth edition, revised and illustrated. Bristol: *John Wright and Sons*; London: Simpkin, Marshall, Hamilton, Kent, and Co. 1914. Pp. 599. Price 9*s.* 6*d.*

THIS synopsis of surgery has had a wide sale, which has necessitated the issue of frequent editions, and it deserves thoroughly all the success it has attained. In this edition the pathological and bacteriological sections have been revised and in great part rewritten by Mr. George Scott Williamson, and they may be taken to represent the latest pathology. There have been many small but important changes required by the progress of surgery, but the plan of the book remains unaltered, and we may repeat what we have said of it before, that if it is used wisely as an adjunct to the larger works it should afford invaluable assistance to the student in the preparation for examination.

Handbuch der Gesamten Therapie.

Herausgegeben von F. PENZOLDT und R. STINTZING. To be completed in seven volumes with about 900 illustrations. Lieferungen 1 to 10. Vol. I. With 35 illustrations and 1 curve in the text. Jena: G. Fischer. 1913-1914. Pp. 986. Price complete, paper, 120 marks; bound, 141 marks.

THE fifth edition of Penzoldt and Stintzing's great Handbook of Therapy is now in process of appearance, and bids fair to be larger and more complete than any of its predecessors or rivals. At the present time only the first of its seven volumes has been published in full, but parts of other volumes have been issued, and the whole work is to be out by the end of the current year. The first edition was printed only 19 years ago; the fifth is to be the work of 85 contributors, all specialists in the subjects about which they write; most are Germans, a few are Austrians or Scandinavians. This handbook, as is well known, aims at thoroughness and completeness, and covers all departments of internal medicine. The first volume deals with the treatment of the infectious diseases, poisonings, disorders of metabolism, and diseases of the blood and of the ductless glands. The second volume will contain the treatment of the diseases of the digestive organs; the third volume that of diseases of the lungs, the circulatory organs, and the genito-urinary tract (excluding venereal diseases). In the fourth volume the treatment of nervous disorders and insanity will be discussed;

in the fifth, diseases of the locomotory apparatus, venereal disease, diseases of the skin and eyes, and treatment with various rays and emanations. The sixth volume will be given to surgical treatment and ear disease; the seventh to obstetrics and gynæcology. It is enough to say that the first volume, admirably got up and furnished with a good index, fully maintains the high standard of excellence set by the previous editions of this well-known handbook. Most of it is well written and to the point, and but rarely does it show the degeneration of thoroughness into longwindedness that not infrequently disfigures, or seems in British eyes to disfigure, the larger German text-books. The new edition of "Penzoldt and Stintzing" should be on the shelves of every medical library, and may be cordially recommended to the attention of all medical practitioners.

The Operating-room and the Patient: a Manual of Pre- and Post-operative Treatment.

By RUSSELL S. FOWLER, M.D., Chief Surgeon, First Division, German Hospital, New York, &c. Third edition, rewritten and enlarged. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 611. Price 15s. net.

ON two previous occasions we have spoken favourably of the earlier issues of this work, and this edition has the good qualities of its predecessors with some additional merits of its own. It is a work of great value for all those who have to organise the operative service of an institution or to carry on the work when it has once started. It abounds in valuable details as to the management of a patient both before and after an operation. In addition to the general chapters relating to operations generally, there are special sections detailing the treatment connected with operations on particular parts of the body. We quote the sentence in which the author sums up his teaching: "Roughly, the underlying principles of successful surgical treatment may be summarised as follows: careful anæsthesia, exact hæmostasis, asepsis, rest of the injured part, use of the rest of the body, feeding advanced to the normal as the anæsthetic-weakened stomach can care for it, and the following of the general rules of hygiene." This edition is much larger than the second, and contains many more illustrations.

LIBRARY TABLE.

Materia Medica Notes. By JAMES A. WHITLA, L.R.C.P. & S. Edin., L.P.S.I. Edinburgh: E. and S. Livingstone. 1913. Pp. 155. Price 2s. 6d.—The author is careful to point out in his introduction that this little volume is not intended to rank as a text-book but rather as a concise companion to any of the text-books on the subject. Taken in this light the book will be found useful both by students and practitioners. The work is divided into three parts. In the first an account is given of the official drugs and their actions. The reason for adopting the plan of considering the drugs before the galenical preparations has been to enable the student to have some knowledge of the drugs themselves before commencing to study their preparations. We certainly think this will be found the more interesting way. The descriptions are well given, and a brief but clear account follows of the action of the drugs. In the second part the galenical preparations are enumerated and their ingredients, strength, and dose are duly stated. In the third part a few remarks are made on prescription writing, and the various classes into which drugs are divided are adequately described. A number of prescriptions are then set out which may be found useful in the early days of practice. The formulæ are given according to the total quantity of the remedies prescribed. We believe that the student will learn prescribing more accurately if the single dose of each constituent is stated; for then he must realise the exact amount of each drug that is used, and "build up" the prescription accordingly. Otherwise prescription writing is apt to become mechanical and simply the result of memory.

A Code System for the Hospital Pathological Laboratory. Part I. *Autopsy Work, being a Students' Guide to the Description of Autopsy Organs.* Pp. 34. Price 35 cents. Part II. *Histological Work: a Guide to the Description of Microscopic Sections of Pathological Tissues.* Pp. 20. Price 35 cents. By O. C. GRUNER, M.D. Lond., Pathologist to the Royal Victoria Hospital, Montreal, &c. 1913. Toronto: Murray Printing Co., Limited; London: H. K. Lewis.—These two brochures are intended to supply a convenient system for preserving in an abbreviated form the notes of pathological findings, a series of numbers being used for sentences descriptive of conditions present. Thus the figures "I. 11." would together mean "Circulatory System: the pericardial cavity is obliterated by tough adhesions," and so forth. In the second part the points to be observed in studying the different organs histologically are indicated, but the code of numbers for recording them is held over for a further part. It is difficult to judge how far such a system might prove useful. It would certainly facilitate the preservation of very brief notes with a key to elucidate them, but it would seem to involve a considerable waste of time both on the part of the pathologist who had to work the code in the first place, and still more of those who had subsequently to decipher it.

Herbal Simples Approved for Modern Uses of Cure. By W. T. FERNIE, M.D. Third edition. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited; Toronto: The Macmillan Company of Canada, Limited. 1914. Pp. 596. Price 6s. 6d. net.—In THE LANCET for Sept. 21st, 1895, we reviewed the first edition of Dr. Fernie's book on herbal simples, the third edition of which now lies before us. We can only repeat our commendation of the large amount of knowledge and research shown by the author, and at the same time express our satisfaction that some of the extreme statements in reference to certain simples have been toned down. The work is much altered since its first appearance. It is 17 years since the second edition was published and we must congratulate the author on his mental vigour at an advanced age, as evidenced by a complete revision of his work, which is now enlarged by additions from another of his works entitled "Meals Medicinal." The book now contains 183 articles on individual herbal substances or groups thereof arranged in alphabetical order with the addition of many crossheads. These articles make reference to upwards of 580 "simples." They contain a vast mass of information, including the folk-lore concerning and references to the various drugs in the literature of ancient and modern times and many lands. The author's style is quaint, and the book is an excellent one to browse on in leisure moments. Here is how he silhouettes the horse chestnut: "Taken altogether, the horse chestnut, for its splendour of blossom and wealth of umbrageous leaf, its polished mahogany fruit, and its special medicinal virtues is *facile princeps*, the belle of our English trees. But, like many a ballroom beauty, when the time comes for putting aside the gay leafy attire it is sadly untidy and makes a great litter of its cast-off clothing." The book ends with a 16 page index of diseases and their appropriate simples.

The Elements of Bandaging and the Treatment of Fractures and Dislocations. By William Rankin, M.A., M.B., Ch.B. Glasg., Dispensary Surgeon, Western Infirmary, Glasgow. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 116. Price 5s. net.—This little book is a valuable guide to the application of bandages, to the use of splints for fractures, and to the reduction of dislocations. In the section dealing with bandaging the author does not describe all the forms of bandages, but he confines himself to those forms which he has found most useful. In the same way in the account of the methods of treatment of fractures only those methods which the author prefers are described. We do not in the least degree find fault with this arrangement; it is probably that which is best for the learner and also for the practitioner who wishes to deal with a condition with which he is not familiar. The author is very emphatic in advising the routine use of anæsthetics in the diagnosis and reduction of fractures. We agree on the whole with this advice, but we cannot help thinking that he lays down rather too absolute a rule, for it must not be forgotten that an anæsthetic is not such a slight matter as many appear to think. On one other point we offer a criticism. In the account of Bryant's triangle, why does the author trouble to mention the third side formed by the line drawn from the anterior superior iliac spine to the tuber ischii? It is absolutely useless and serves to confuse the student. This author is not alone in this; nearly all the text-books err in this matter. It is, indeed, far better to speak of "Bryant's line," for it is only the base of the triangle which is important. The book is well illustrated.

MISCELLANEOUS VOLUMES.

In *How to Become Efficient* (London: T. Werner Laurie, Limited. Pp. 144. Price 1*s.* 6*d.* net) Mr. T. Sharper Knowlson states that "the underlying idea of efficiency is to do whatever we have to do in the right way." Lack of efficiency, he says, is shown by waste substances and waste movements. This idea, he proceeds to demonstrate by many illustrations drawn from various phases of industrialism, can be attained by the application of "the scientific method" to materials, methods, and men in business life. After an extension of the argument in greater detail he proceeds to the consideration of efficiency in politics, municipalities, and the home, and finally arrives at personal efficiency, which is really the substance of all other efficiency, since no kind of organised, coöperative, or corporate efficiency can ever rise higher than the quality of its constituent members. Here the question of efficiency in education naturally comes in, and what he has to say is for the most part sensible and sound, if not above criticism in a few particulars.——As in the case of her "Care of Infants," Dr. Mildred Burgess in *Health* (London: H. K. Lewis. 1914. Pp. 175. Price 1*s.* 6*d.* net) has followed the syllabus of the London County Council's course of lectures on this subject, and this work includes much matter therefore that has hitherto had to be culled from different books. The subjects dealt with are the Phenomena of Life, Air and Ventilation, Water, the Dwelling House, Food and Feeding, Diseases connected with Food, Clothing, Personal Hygiene, Exercise, and Infectious and Communicable Diseases. The original diagrammatic illustrations by Miss Cartwright are very useful and there are coloured plates representing food values and the commoner disease germs respectively. In this way there is conveyed a great amount of very practical information, so far as we have had an opportunity to observe scientifically accurate, yet expressed in language easily comprehensible by any intelligent person. The chapter on the dwelling house contains much information that it would be hard to find elsewhere.——*Demonstrations on Infant Care* (London: G. Bell and Sons, Limited. 1914. Pp. 53. Price 8*d.*), by Mrs. Kate Truelove, with an introduction by Lady St. Helier is interesting. That all girls should have their natural mother instinct as displayed in their universal fondness for dolls turned to advantage by cultivation in mothercraft during childhood seems sensible enough, and in this little book a syllabus is given of the method of teaching infant care which the writer has found effective and interesting, by allowing the girls to demonstrate with a washable doll. The demonstrations include the whole ritual of bathing, weighing, dressing, feeding, and resting baby, with elementary instruction what to do in convulsions, concussion, choking, burns, scalds, wounds, and cuts. The information given appears to be entirely sane, practical, and adequate. There are many useful illustrations, and the book is nicely bound and well got up.

In *A Description of the Imperial Bacteriological Laboratory, Muktesar: its Work and Products*, by Major J. D. Holmes, D.Sc., M.R.C.V.S., Imperial Bacteriologist (Calcutta: Government Printing Press. 1913. Pp. 125), a short history is given of the work carried on in the Himalayan hills in India, to which reference was made in our issue of Jan. 17th (p. 193). There are numerous illustrations, and a good idea is given of the equipment and practical management of such an institution, and of the benefits, sanitary and financial, that accrue to the community from its existence.——The second volume of the *Transactions of the Ninth Session, Australasian Medical Congress, 1911* (Sydney: W. A. Gullick. 1913. Pp. 733 to 1346), contains the papers read in the Sections of Ophthalmology; Psychological Medicine; Diseases of Children; Naval and Military Medicine and Surgery; Dermatology; Radiology and Electricity; and Laryngology, Rhinology, and Otology. Many of these are of great interest and show the rapid advance that is taking place in all branches of medical knowledge in the great Commonwealth of Australia.——*The Transactions of the Medico-Legal Society, 1912-1913*, Vol. X. (London: Chas. Griffin and Co., Limited. 1913. Pp. 209), edited by William A. Brend, contains the presidential address of Earl Russell on the Relationship between Medicine and Law; and papers on Shock, by F. G. Crookshank, M.D.; Legal Problems Relating to Medical Services under the National Insurance Act, by Roland Burrows, LL.D., barrister-at-law; Responsibility in Regard to Certain Forms of Unsoundness of Mind, by Robert Armstrong-Jones, M.D.; First Steps Towards a State Medical Service, by Professor B. T. Moore (commented on in our columns of May 24th, 1913, p. 1469); the Examination of Minute Traces of Blood for Medico-Legal Purposes, by Professor Harvey Littlejohn, M.B.; and the Necessity for Amendment of the Law Relating to Coroners and Inquests, by W. A. Brend, M.B., barrister-at-law.[1] The Transactions are now under the editorship of Mr. R. Henslowe Wellington.

Mr. T. Gibson Bowles has published, with an introduction by himself, the proceedings in court and official court documents in the case of *Bowles* v. *The Bank of England* (London: Butterworth and Co. 1914. Pp. 152). This case, it will be remembered, was brought on public grounds to restrain the Bank of England, as the agents of the Treasury, from deducting income tax before it had been rendered legally due by the passing of the Finance Act. The judgment affirmed the principle the maintenance of which cost John Hampden his life, with the practical result of ensuring the passing of the Finance Act imposing the year's income tax by August each year.

The papers set at examinations are eagerly sought by students both for the purpose of showing the trend of questions likely to be asked of them and as material for study and revision. In *Fellowship Examination Papers for the Diplomas of the Royal College of Surgeons, Edinburgh* (Edinburgh: E. and S. Livingstone. Pp. 80. Price 1s. net), we have the papers set at these examinations from 1906 to 1913; and in *Dental Examination Papers for the Diplomas of the Royal College of Surgeons, Edinburgh, and the Royal Faculty of Physicians and Surgeons, Glasgow* (same publishers and price. Pp. 90), the questions cover the same period of time.

JOURNALS AND MAGAZINES.

The Military Surgeon. Chicago, U.S.A. Edited by Brigadier-General SAMUEL C. STANTON, Illinois National Guard (retired).—Major Robert Brooke reports in the number for March that Cebu, in the Philippine Islands, is exempt from malarial fever. He investigated the mosquitoes present, and succeeded in capturing only Culex fatigans, and of the anophelinæ only Myzomyia rossii and M. ludlowi, in which the malarial parasites are not found or do not go on to complete development. Major Brooke has not so far been able to determine the condition which prevents the settlement of ordinary anopheles in this district. As he says, the solution of this problem is worthy of much consideration, and may lead to measures valuable in the prevention of malarial fever. We hope he will tell us more by and by.—Major W. N. Bispham has a good paper on Malingering. One of his patients was very deaf. He was told to blow his nose. As he pulled out his handkerchief an orderly dropped a halfcrown on the floor and the deaf patient stooped down quickly to get it and was sent to duty.—Captain Louis C. Duncan presents an account of the medical services in the Russo-Japanese War, apparently translated from the Swiss. All the praise is given the Japanese. The Russian doctors seem to have been paralysed through not having an autonomous organisation. The senior officers of the larger medical units were laymen, generals and the like, and of course not the best generals. The same difficulty was noted amongst the Russians in China in 1900; they require many more officers than other soldiers, being so accustomed to have all initiative forbidden them, and sanitary detachments were sometimes on the spot where they were wanted but would do nothing for want of orders. As there was no routine for searching out and removing the wounded, a severely wounded man and his kit were quite often removed to the rear by six comrades from the firing line. The number of wounded, also, was overwhelming, and at the front there were only unwarmed horse-trucks for them, so many were frost-bitten on the way back; also, for lack of staff to feed them, they were starving. But Russia is capable of great things, and the service of the Red Cross and the Empress's hospital trains did an enormous amount of first-class work.—The annual report of the general in charge of the United States militia notes how sketchy is its sanitary organisation. Each State provides its own militia, and the results are uneven. While Massachusetts has 44 medical officers and 146 men, Louisiana thinks it worth while to raise only 2 medical officers and 22 men. An appeal is made that each man enlisted shall be vaccinated against typhoid. Enough vaccine was issued last year for 15.000 men, but the number on whom it was used is not stated. There would seem to be some red tape used in the War Office of even so free and enlightened a republic as the United States of America, for the question of a telephone for a surgeon at a Philadelphia hospital had to go to the Judge Advocate General to decide if it could be borne by public funds.

The American Journal of Tropical Diseases and Preventive Medicine. New Orleans. Edited by CHARLES CHASSAIGNAC, M.D., and ISADORE DYER, M.D. $2.50 a year; single copies, 25 cents.—The March issue contains an article on an Epidemic of Paratyphoid Fever, by A. N. Sinclair, bacteriologist to the Territorial Board of Health, Hawaii, the gist of which is that the outbreak appears to have been traced to a carrier whose fæces contamined the excremental manure, so that the disease was disseminated by vegetables.—Foster M. Johns and Percy L. Querens give a further Note on the Growth of Filarial Embryos in Vitro, in which the embryos of filaria immitis and setaria labiato-papillosum in dextrose defibrinated blood respectively from dog and cattle exhibited growth and motility for 15 and 52 days, after which degeneration of both media and organisms occurred.—Echeverria cites experience in Costa Rica to demonstrate the innocuousness of bites by the malaria and yellow fever mosquitoes during the daytime.—William H. Deaderick gives the outline of an elaborate scheme of search for municipal sanitary defects.

Bulletin Mensuel de l'Office Internationale d'Hygiène Publique. Paris: Office International d'Hygiène Publique, Boulevard Saint-Germain.—We have before us the last issues of this valuable periodical, which was started by international arrangement some eight years ago. The number of nations actually participating in the work of the International Sanitary Office is 31, but to attain this total we reckon Great Britain, British India, Australia, and Canada separately. Many small nations participate and most of the large ones, but Germany is absent. This does not prevent the publication of a considerable amount of news from, or documents dealing with, Germany. Thus the February number gives the latest German enactments relating to measures against leprosy, and the new regulations for the inspection of ships passing through the Kiel canal. Somewhat disheartening information is recorded from Spain. In spite of the terrible lesson taught by devastating epidemics, and the generally speaking high death-rate, the fundamental question of the water-supply of Spanish communities has made but little progress towards solution. A Royal Order has been issued by the Government which commences with the announcement that there are on an average 50,000 cases of typhoid fever annually in Spain, resulting in at least 7500 deaths, and adds that a pure water-supply is the best preventive. In Spain there are immense obstacles yet to be surmounted. There is neither the knowledge nor the money necessary to improve the water-supply of the country generally. Therefore, and as being easier to manage, and above all much cheaper, this Royal Order recommends all the local authorities to encourage the employment of antityphoid vaccine. Yet without going further than the *Bulletin* before us, page after page contains elaborate descriptions of what has been done in almost every part of the world to increase, to purify, to filter, and to sterilise the water-supply of towns and the country. The same may be said concerning the prevention of the contamination of rivers and water generally by the treatment and purification of sewage. Indeed, the *Bulletin* through its monthly issues is a compilation of the laws enacted, the public works undertaken, and the sanitary experiments made in all the civilised parts of the world, and deserves wider publicity.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the twenty-ninth meeting of the Royal Commission on Venereal Diseases evidence was given by Sir Victor Horsley. He said that the experience of the last 25 or 30 years led to the conclusion that these diseases were decreasing in virulence; it was his impression, however, that they were extremely prevalent. It was not possible to speak statistically of the amount of prevalence, and the position in this respect would not be remedied until confidential registration of deaths had been adopted. This reform had been advocated by the British Medical Association for many years. The Association also put forward some 10 years ago the proposal that in every coroner's district there should be an officer appointed whose duty it would be to make such post-mortem examinations as might be necessary to determine the exact causes of death. That proposition had relation not merely to ordinary deaths, but above all to the examination of stillborn children; if it had been accepted the Commission would have been in possession of material relating to ante-natal conditions revealing the exact prevalence of syphilis. It was very desirable that this arrangement should be carried out with a view to the discovery of ante-natal conditions, not merely syphilis, but other pathological states. The Notification of Births Act under which stillbirths are notifiable should be compulsorily extended to the whole country. Sir Victor Horsley was of opinion that the education of the public in regard to venereal diseases was enormously important, and that children should be instructed in sex matters. If the nature study part of elementary education were extended and every child taught the groundwork of hygiene; the health of the body, the instruction in sex matters could without injury gradually be brought into the mind of the child. So far as education related to reproduction in man it should be given individually and not as class instruction. In secondary schools children should receive full instruction. At the present time instruction was also necessary for adults. The teaching should be given by laymen; if it were in the hands of medical men it would be regarded as part of a medical mystery.

Sir Victor Horsley dealt at some length with the difficulty with which medical practitioners are frequently faced in public health matters by reason of the law of libel. It was perfectly obvious, he said, that from the public health point of view a medical practitioner ought to be able to warn somebody who to his knowledge was likely to be infected with venereal disease, but under the law as it stood he would render himself liable to a libel action and would undoubtedly be ruined. A medical man ought to be able to state what he thought was the cause of a particular disease, but the information should only be given to people who had a right to demand it. Sir Victor Horsley said that he was in favour of the notification of venereal diseases to the medical officer of health. He thought that a system of notification would not improbably be resented both by medical practitioners and by the public, but the history of notification showed that objections had been very strongly brought forward even in regard to the simplest diseases. The notification of scarlet fever was violently resisted at first, but there is no difficulty about it at the present day. Every argument that he had heard used against the notification of venereal diseases had also been used against the notification of so-called simpler diseases. The notification should be confidential and he had no fear of its confidential character being invaded; for this reason he did not think that a distinction could be drawn between venereal and other diseases on the ground that a moral stigma might be alleged in the case of the one and not in the case of the other. With regard to the diagnosis and treatment of venereal diseases Sir Victor Horsley said that he was in favour of treatment in special wards of general hospitals, and he thought that every health authority should have its own bacteriological laboratory for the diagnosis of disease. He did not think that adequate facilities for diagnosis or treatment would be provided unless there was a subsidy from the State.

At the thirtieth meeting Dr. Florence Willey, assistant physician for diseases of women at the Royal Free Hospital, gave evidence.

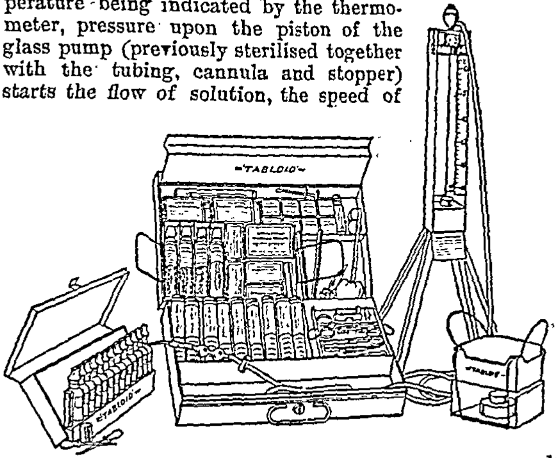
Dr. Willey urged strongly the need for early and effective treatment of both gonorrhœa and syphilis, and said that in order to secure such treatment it was necessary to provide, firstly, for the early and scientific diagnosis of all suspicious cases, and, secondly, for some means of efficient treatment of such a nature that infected persons would willingly avail themselves of it. It would be necessary, she thought, to provide free of cost facilities for carrying out Wassermann tests and bacteriological examinations and for the post-mortem examination of stillborn children and miscarriages. The results of such post-mortem examinations should be notified to the medical man attending the case in order that he might be enabled to secure efficient treatment for the mother in cases which were shown to be syphilitic.

Dr. Willey thought that clinics for the treatment of venereal diseases should form part of the work of an institution not wholly devoted to those diseases; they should preferably be part of the work of a general hospital and should be arranged at hours convenient for the working classes. Evening clinics, she said, were very desirable. On the question of notification Dr. Willey said that she was strongly of opinion that any scheme of notification by name would defeat the end in view, and she therefore advocated that all material sent for diagnosis should be identified by number only. She further suggested that all patients under treatment should be given definite instructions which would enable them to avoid infecting other people and that all nurses should be fully instructed in the nursing details of these cases and in the special precautions necessary in each disease to avoid infecting themselves and other patients. As a preventive measure she thought the instruction of young people in matters of sex hygiene was very desirable.

New Inventions.

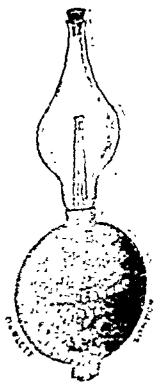
"TABLOID" BRAND MEDICAL EQUIPMENT FOR THE TREATMENT OF CHOLERA.

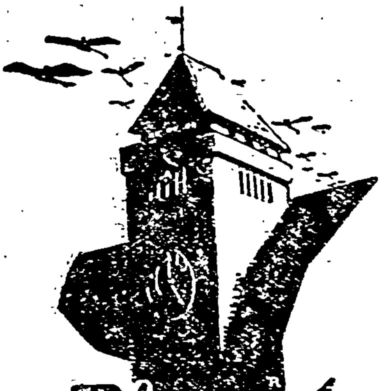
AN obvious advantage in the treatment of cholera by the intravenous injection of saline solutions is the suitable provision of all the apparatus needed. The "Tabloid" medical equipment No. 363 (Messrs. Burroughs, Wellcome, and Co., Snow Hill Buildings, E.C.) is compact and complete, and contains several improvements which facilitate the somewhat complicated technique of this treatment. The saline solution, made from the "Soloid" products in the case, is sterilised in the 25 oz. flask by heating over the spirit lamp, and on the desired injection temperature being indicated by the thermometer, pressure upon the piston of the glass pump (previously sterilised together with the tubing, cannula and stopper) starts the flow of solution, the speed of which can be read in a few seconds by the simple scale and controlled by the special pattern regulator. The sphygmometer and the set of glycerine dilutions enable the patient's blood pressure and the specific gravity of the blood to be readily ascertained. Every other detail necessary for the treatment of cholera by saline transfusion, as advocated by Lieutenant-Colonel Leonard Rogers, I.M.S., is included in this equipment. The items include: Metal and glass cannulas, an all-glass hypodermic syringe, forceps, bandages, clinical thermometer, "Vaporole" iodine tincture for sterilising the site of injection, "Vaporole Infundin" pituitary (infundibular) extract, and a steriliser for instruments, rubber tubing, &c. In addition to these, supplies of "Tabloid" potassium permanganate (keratin-coated) and "Tabloid" calcium permanganate (keratin-coated) are included.



THE "HANDIESQUE" SPRAY.

THE simplicity of construction of this spray apparatus will be apparent from the accompanying illustration. It consists of a pear-shaped glass bulb in the centre of which is a narrow glass tube through which air is forced by means of hand compression bellows. We find that it gives a fine spray, whether oily, aqueous, or spirituous solutions are used. Its application is indicated chiefly in the local treatment of morbid nasal and pharyngeal conditions. It is very compact and light and is easily cleansed or sterilised. The bulb is made of toughened glass, and its contents can be preserved by fitting a cork into the neck. It reduces the ordinary inconveniences of a spraying apparatus to a minimum. The "handiesque" throat and nose spray has been introduced by Messrs. C. J. Hewlett and Son, Limited, of 35–42, Charlotte-street, London, E.C.





Biomalz

(Biomalt),

a Food which is very extensively recommended by Medical Men abroad, is prepared from high-class barley-malt, with the addition of calcium-glycerine-phosphate, and is now obtainable in Great Britain at all Chemists and Druggists. Samples and literature may be obtained post free from the Wholesale Depot of "Biomalz," REGENT HOUSE, KINGSWAY, LONDON, W.C.

RADIOGEN.

RADIUM PREPARATIONS

KEEP INDEFINITELY and are GUARANTEED of STANDARD STRENGTH

RADIOGEN DRINKING WATER (1000 Mache). As prescribed by Eminent Physicians in England and on the Continent.

RADIOGEN CAPSULES. (For Oral Administration.)

RADIOGEN TABLETS. (Used in the treatment of Diseases of the Mouth and Teeth.)

RADIOGEN PASTE. (For Dental Massage.)

STERILE RADIOGEN SOLUTION. (For Irrigation in Pyorrhœa Alveolaris.)

RADIOGEN COMPRESSES. (Permanently Radioactive.)

RADIOGEN EARTH. (For the preparation of Radioactive Mud Baths.)

RADIOGEN EMANATORIUM.

FOR INSTALLATION IN HOSPITALS, HYDROS, SANATORIUMS, AND NURSING HOMES.

Used in the treatment of

GOUT, RHEUMATISM, ARTHRITIS, NEURITIS, and CONCOMITANT AFFECTIONS.

See "BRITISH MEDICAL JOURNAL," February 4th, 1911, page 243.

CHAS. ZIMMERMANN & CO. (CHEMICALS), Ltd., 9 & 10, St. Mary-at-Hill,

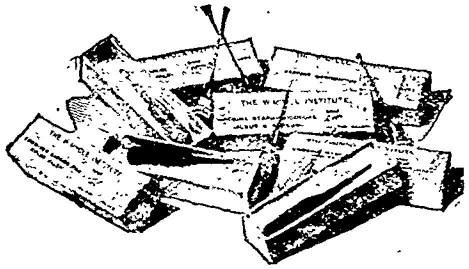
VACCINES

OF THE WIMPOLE INSTITUTE.



Acne Bacillus.—5 millions, **1/6** ; 10, **2/-** ; 20, **2/6** ; 50, **3/-**.

Acne with Staphylococcus.—Acne, 5 millions with Staphylo., 100 millions, **2/-** ; Acne, 5 with Staphylo., 250, **2/3** ; Acne, 10 with Staphylo., 250, **2/6** ; Acne, 10 with Staphylo., 500, **2/9** ; Acne, 10 with Staphylo., 1000, **3/-** ; Acne, 10 with Staphylo., 2000, **3/6** ; Acne, 20 with Staphylo., 2000, **4/-**.

Staphylococcal (Albus or Aureus, or both mixed in equal proportions).—Albus or Aureus, or mixed: 100 millions up to 4000 millions, **1/-** to **5/-**.

Combined Vaccine for Colds.—Arranged to suit prevailing epidemic, 25 millions of each, **2/6** ; 50 millions of each, **3/-** ; 100 millions of each, **4/6**.

Coli Communis.—10 millions, **1/9** ; 25, **2/-** ; 50, **2/3** ; 100, **2/6** ; 250, **3/-** ; 500, **4/-**.

Dysentery.—4 strengths. Prices **2/6**, **3/-**, **4/-**, **5/-** respectively.

Gonococcal.—10 millions, **1/6** ; 25, **1/9** ; 50, **2/-** ; 75, **2/6** ; 125, **3/-** 250, **4/-** ; 500, **6/8** ; 1000, **10/6**.

Hay Fever.—5 strengths, **2/-** each. For curative purposes first dose should be No. 1, followed at intervals of a few days by Nos. 2, 3, 4, 5.

Meningococcus.—5 millions, **1/6** ; 10 millions, **1/9** ; 25 millions, **2/-** ; 50 millions, **2/6** ; 100 millions, **3/6** ; 250 millions, **5/-**.

Micrococcus Catarrhalis.—50 millions, **2/-** ; 100, **2/6** ; 250, **3/-**.

Ozæna.—50 millions, **2/-** ; 100 millions, **2/6** ; 250 millions, **3/6** ; 500 millions, **5/-** ; 1000 millions, **7/6**.

Pneumococcus.—10 millions, **1/9** ; 25, **2/-** ; 50, **2/6** ; 100, **3/6** ; 250, **4/-** ; 500, **5/-**.

Streptococcus.—10 millions to 500 millions, **1/-** to **5/-**.

Streptococcus Rheumaticus.—For the complications of rheumatic fever, **2/6** a dose of 10 millions ; 25, **3/-** ; 50, **3/6** ; 100, **5/-**.

Diphtheria (as an Adjuvant to Antitoxin).—10 millions, **1/9** ; 25, **2/-** ; 50, **2/6** ; 100, **3/6** ; 250, **5/-**.

Influenza.—10 millions, **1/9** ; 25, **2/-** ; 50, **2/6** ; 100, **3/-** ; 250, **4/-** ; 500, **5/-** : 1000, **7/6**.

Tuberculin T.R. (Human or Bovine), or Bacillary Emulsion (B.E.) ditto.

Human or Bovine Types, large range of doses from 0·00001 c.c. T.R **1/-**, up to 0·1 c.c., **4/-**.

Human and Bovine Mixed.—**3d.** on each price above up to the 0·001 c.c. inclusive. **6d.** on each price from 0·002 c.c. to 0·1 c.c.

Typhoid Vaccine (No. 1).—Broth Cultures of B. Typhosus. 500 millions, **2/-** ; 1000, **3/-** ; 2000, **4/-**. (No. 2).—B. Typhosus with Paratyphoid. 500 millions, **2/6** ; 1000, **3/6** ; 2000, **5/-**. Immunising agents. (No. 3.) For Treatment.—Initial dose 50 millions, repeated or increased at about 3 days, or each subsequent rise of temperature. 50 millions, **2/3** ; 100, **2/6** ; 250, **3/-** ; 500, **4/-**.

Whooping Cough (Bordet's Bacillus).—Of decided service in lessening the violence of the paroxysms and shortening the duration of the attack. 25 millions, **2/-** ; 50, **3/6** ; 100, **4/-** ; 250, **5/-**.

Pyorrhœa Alveolaris.—50 millions, **2/-** ; 100, **2/6** ; 500, **4/-**.

Special "Vaccine" Syringe.—All glass, with suitable, rather wide, needle, **5/-**.

Messrs. WOOLLEY & CO., Manchester, also Messrs. KEMP & CO., Bombay, hold a representative stock.

The State, the Mother, and the Child.

STUDENTS of current social movements cannot fail to observe the strength of the efforts which are now being made to extend State action in all that relates to maternity and infant welfare. To this there are many contributory causes, the most prominent perhaps being the attention which has been evoked by the operation of national insurance to the disabilities entailed on working women by pregnancy. Simultaneously, as a result of the work of public health authorities in connexion with notification of births, it has become realised that excessive infant mortality to a very large extent occurs during the first few weeks of life, in circumstances often to be attributed to malnutrition or definite illness of the mother, to inefficient midwifery, or to other remediable conditions. Then, again, education authorities, which now undertake systematic medical examination and treatment of children who have reached school age, have found that the ailments or defects of the children should in many cases have been detected and dealt with before the age of compulsory school attendance was reached, or might have been prevented altogether by suitable advice to the mother or hygienic management of the child at an earlier stage. An extreme instance, for example, is the child coming to school showing the results of congenital syphilis, which need not have developed if syphilis of the mother had been detected in the ante-natal period. Towards meeting the demand thus arising, much is already attempted or done by various official bodies, so far as their functions permit, and as much, or perhaps more, by the large number of semi-official and voluntary associations which in one form or another undertake what is termed "infant-welfare" work, and by charitable institutions and maternity hospitals. But the multiplicity of uncoördinated work by existing authorities and organisations in advising, visiting, inspecting, and treating mothers and infants causes much inconvenience and waste of effort, besides being incomplete in many essential respects.

A movement to obtain a new and better order of things, lately organised by the Women's Coöperative Guild, deserves special attention, as it is typical of much which is being proposed in other quarters. Briefly, it is a proposal for local municipal action, largely at the cost of national funds, to establish maternity centres to supply medical and nursing supervision for pregnant women of the working class, to provide and pay municipal midwives, to support maternity hospitals, and to supervise the health of the child until school attendance begins by a large extension of home visiting, infant consultations, and clinics. It is suggested that as an "endowment of motherhood" the sum of £7 10*s.* (absorbing the present maternity benefit) should be granted by the State for every child born, the major part of which would be given to the mother in connexion with the municipal supervisory system. Social reformers who are individualists, if any such remain, may question the expediency of State action in such directions as these, on the ground that parental responsibility will be further weakened, and may object to opening the door widely to further innovations, such as the municipal nursery and crêche, which would probably follow on a considerable scale. The eugenist also may ask, without much expectation of being satisfied, what steps the State proposes to take to see that the children thus encouraged and adopted are the right material for the next generation, arguing that the more desirable class will be less disposed to supply children for municipal officers to bring up, so that the stock will be recruited from the less efficient. Such arguments, however, usually appear to be pleas for inaction, while the supporters of the movement to which we refer have behind them substantial and practical reasons for requiring something to be done, in which they are unquestionably in accord with the general spirit of the time. In its medical aspects there need be no hesitation in supporting the contention that if national money and organisation are made available much invalidism of mothers, and death and disabilities of children, can be prevented. The recent trend of medical work, including developments in the education of medical students as to the care and hygiene of infancy, tends to increase the efficiency of the service which medical science is already able to render in this direction.

The movement towards more definition for the work which the State can undertake in behalf of the mother and the child appears to have received an encouraging reception from the Government, and evidence of its practical progress is afforded by an active controversy which is proceeding as to the national authorities by which official maternity and infant welfare work should be carried out. On the one hand it is contended that the local education authorities, under the direction of the Board of Education, are already, with the aid of national funds, so organised that development comes naturally through the enlargement of the school medical inspection service, the further training of midwives by education authorities, the education given in the schools in matters of hygiene to the mothers of the future, and generally through the adaptation of much organisation which is well developed under the education authorities and ready to hand. To this it is replied that by similar arguments almost any administrative work in the country could be brought within the category of education, and that it is only an accident of our administrative system which makes it possible to think of imposing these duties on education authorities and not on the sanitary authorities, to which they would naturally fall. It would certainly seem shortsighted to ignore in this connexion the extent to which many sanitary authorities, under the direction of the Local Government Board, have already developed home visiting and other work in connexion with the Notification of Births Act, while it seems useless to hope for the success of educational methods of hygiene in overcrowded and insanitary environment. It is on every ground desirable that these administrative problems should be freely brought to notice and publicly discussed at the present time. Recent experience has shown that the bringing of schemes of social improvement which are dependent on medical considerations into the arena of politics and legislation is not without its dangers. It is flattering to medical science that the politician should take it for granted that medicine can work wonders, if only a new measure is passed or a new form of administration is set up which is convenient to the political or departmental conditions of the day. But care must be taken that medical science is given a fair chance, and too much thought can hardly be given to the essential objects which [illegible] in view in any new administration [illegible]d to set up.

with no dormant focus of disease and no irr damage. Disease is too often considered as a condition, an incubus which can be sha whereas it should be regarded as a dynamic a progressive and active interference with whether produced by chemical, mecha bacterial agencies, and whether inherit genous, or exogenous in origin. of the organism the recovery from many ific diseases appears to be complete and , and cure is thus the rule; but this is by the case in all, as the immunity conferred mporary only, and may in some cases be y increased susceptibility. When a poison eutralised by its antidote or got rid of by ry channels of the body we may speak of the other hand, where a disease process uited or shut off and its further spread while the causal agent remains we ak of arrest, but not of cure. Where nic damage has occurred and function stored by vicarious activities we should e result as one of repair or compensa- a duty which the medical profession e public to explain the distinction overy and cure.

Annotations.

"Ne quid nimis."

KUBISAGARI.

ation paper set by students for their s no doubt unlikely to become an fact, though to many a student the ibility must have occurred. If such set in medicine it might well open estion "State what you know of The candidate could not take shelter cuse that the matter is one that has attention in the text-books, for it is ed in Sir William Osler's well-known medicine. Kubisagari is a disease two small districts only, so far as is ne in North Japan, the other on the frontier. Doubtful sporadic cases ported elsewhere, but in these two ed areas the disease appears to be both there is a seasonal incidence, May and June, reaching its height in , and ending in October or November. oud, who contributes an interesting subject to the *Presse Médicale* for story which shows the origin of the of the disease. A young Japanese d just settled in a rural district in hen one day he found a *peasant* at is head bent forward on his breast. ed as to what he wanted he was at speak, but he was soon able to e was "kubisagari" (drop-head), the by the villagers to a complaint to ad long been subject in the summer he symptoms are paresis of various coming on suddenly during use of the d parts, disappearing with rest, and returning ttempts to put them into action once more, of vision developing in the same rapid manner, vertigo. For example, during milking the im finds his hands become numb and useless, ead falls forward against the cow, and he rolls on the ground. Gerlier, who was the first to ve the French cases, found that there was a l paralysis of the extensors of the fingers. attack lasts about ten minutes, but one bout may run on into another. Various muscles may be affected, but fatigue is an essential provocative. As soon as the autumn comes recovery ensues in all cases. The attack usually begins in the afternoon, when the patient is tired; the duration of the illness is variable up to five months. In spite of deliberate and exhaustive study in both the districts affected nothing of importance was discovered as to the etiology, apart from these data—that cats and poultry might be affected, and that there was an indubitable connexion between the incidence of the disease and work in certain particular stables. It appears also that suckling infants are liable to acquire the malady if the mother is suffering from it. It is not to be wondered at that an infective origin should have been suspected, and it is mainly with the purpose of describing his bacteriological researches that Dr. Couchoud has written his paper. His positive findings are briefly as follow. From the cerebro-spinal fluid and from the milk of persons suffering from the disease he was able to cultivate a micrococcus grouping like a staphylococcus, growing on agar, not liquefying gelatine, and Gram-negative. Injection of cultures into cats reproduced the characteristic symptoms in two or three hours in a large majority of the experiments. Dr. Couchoud acknowledges that his observations must be confirmed by other observers before they can be generally accepted, and he points to the scientific interest of this singular disease as an inducement to research in a somewhat restricted field.

DR. WILLIAM HAWES AND THE ROYAL HUMANE SOCIETY.

Now that London is at last to be given an adequate ambulance service, it is interesting to call to mind the early philanthropic labours of Dr. William Hawes, an old Pauline and one of Oliver Goldsmith's medical attendants. The poet, as is well known, hastened his end by an excessive use of Dr. James's fever powders, of which course his doctors disapproved. Dr. Hawes was led to publish a work on the illness and death of Goldsmith in order that he might warn the public, in a self-drugging age, against using powerful medicines without due medical advice. The profits of the publication were employed to help in founding what was afterwards known as the Royal Humane Society. Dedicating the book to Sir Joshua Reynolds and Edmund Burke, who had deputed Hawes to manage the doctor-poet's bankrupt estate, Hawes says (p. 21): "As my late respected and ingenious friend Dr. Goldsmith was pleased to honour Dr. Cogan and myself with his patronage and assistance in the plan for the recovery of persons apparently dead, now on the point of being established in this kingdom, I think I cannot show a greater proof of my esteem for the deceased than by applying the profits of this publication to an institution the design of which was favoured by his warm approbation." This was written in 1774, and in 1781 Hawes published an address to Parliament on the importance of the Humane Society, on the score of humanity, philanthropy, and sound policy, and stated therein a variety of consequences which might be reasonably expected to follow the establishment of receiving houses. These were to be scattered over London, and thither the victims of casualties were to be carried. Nothing is said of an ambulance service, but a curious picture is painted of sudden death and street accidents in an age when these were even more frequent than at present. "When sudden death happens (see Hawes—'Address to the King and Parliament of Great Britain,' edit. 3) by accident in the public street, or other places on land, too often the consideration of inconvenience overcomes the dictates of humanity, and no friendly door is open to receive the body; or, if there is, the attendants are ignorant of their duty." Hurriedly called in, the medical man finds a scene of real confusion. If poor, the victim of the accident lies in the open street among "a croud." If the apparent corpse shows signs of prosperity, "it may perhaps be raised from the ground and placed on a shop floor." The medical man always has to regret the absence of "necessary as well as proper assistance." First aid was not then taught, and Hawes at this time became its pioneer. He delivered lectures and distributed pamphlets gratis on the modes of recovering persons from syncope, inebriety, trance, drowning, suffocation by the cord, or noxious vapours, intense cold or lightning, and on stillborn children and the effects of poisons, and on the certain signs of death. These lectures closed in 1782 with an adjudication of prize medals, offered by Dr. Hawes. The first gold medal was presented to Dr. Pearson, of Birmingham, on behalf of the Humane Society by Dr. Lettsom, Dr. Fothergill, and others, his being considered the best dissertation on the question, "Are there any positive signs of extinction of human life, independent of putrefaction? If so, what are they? Or, if there be not, is putrefaction a certain criterion of death?" The medal bore the name of Dr. Hawes, the donor, and the now famous motto, "Lateat scintillula forsan." The Humane Society was actually founded in 1774 through the joint efforts of Fothergill, Hawes, and Cogan. In 1784 the classical-looking receiving house was built near what was then known as the Serpentine River. It was chiefly designed for the purpose of restoring animation in those who had been "plunged into the contiguous stream." At the time of its erection it was considered without rival in Europe, and it remains to-day to remind a careless generation of the zealous philanthropy of the latter part of the eighteenth century—a philanthropy inspired by lofty motives, however fantastic or inadequate in its realisation. Dr. Hawes was typical of his age, a good talker, with a strong sense of humour which must have endeared him to Goldsmith. But it is for his characteristic public spiritedness that he will be remembered in the history of his time.

TROPICAL DISEASES RESEARCH FUND.

THE report of the advisory committee for the Tropical Diseases Research Fund for the year 1913 has just been presented to Parliament and is now issued as a Blue-book (Cd. 7261)[1] by the Colonial Office. The committee, which was constituted by the Secretary of State for the Colonies in July, 1904, is now composed as follows: The Right Hon. Sir J. West Ridgway, chairman; Sir Thomas Barlow, Sir John Rose Bradford, Sir David Bruce, Sir R. Havelock Charles, Mr. F. H. Drake, Sir Patrick Manson, Mr. H. J. Read, Sir Ronald Ross, and Mr. J. A. C. Tilley, with Mr. A. B. Keith as secretary. The late Sir A. M. Branfoot, who had been a representative of the India Office from the first, resigned from the committee before this report was prepared, and his colleagues place on record their high appreciation of his constant interest and the services which he rendered. The report itself occupies barely two pages, the rest of the volume of 240 foolscap pages being devoted to detailed appendices. The first of the six appendices consists of reports on anti-malarial measures in the Crown colonies, protectorates, &c.; the second is the report of the professor of protozoology in the University of London, Professor E. A. Minchin, for the year ended June, 1913; the third is the report for 1913 on the work of the Quick Laboratory, Cambridge, by the director, Professor G. H. F. Nuttall; the fourth comprises reports from the London School of Tropical Medicine; the fifth contains corresponding reports of the year's investigations at the Liverpool School of Tropical Medicine; while the sixth appendix contains reports on work done in various colonial laboratories. These appendices include a large amount of valuable information from a large number of sources, and further reference will be made in these columns to the results of some of the more important investigations which are detailed therein.

THE RELATION OF APPENDICITIS TO UMBILICAL COLIC IN CHILDREN.

A CONDITION has lately been described as "relapsing umbilical colic" by Professor E. Moro,[1] of Heidelberg. He points out that it is not infrequent in children over 4 years, that it recurs at regular intervals, and that the patients are, as a rule, neuropathic. He considers the attacks have no connexion with appendicitis, and he gives the following account of their most salient features. The child suddenly becomes pale and complains of violent pain in the region of the umbilicus, or between it and the ensiform process. The pain begins without apparent provocation, and frequently occurs while the child is at play, making him press both hands upon his abdomen. An attack may also occur while he is walking, sitting at table, or eating, but never in school. Such an attack may only last a couple of minutes or several hours, and it invariably recurs sooner or later. Not infrequently the attacks recur at regular intervals of two or three months, and they are seldom accompanied by vomiting. In three cases in which this did occur it was periodic or acetonæmic. The temperature is never very high, whereas a subfebrile temperature of 100·4° F. in the rectum is common. In 15 out of 18 cases the patients suffered from constipation, which was frequently accompanied by meteorism and rigidity of the abdominal wall. The parents would sometimes state that castor oil or an enema had at once relieved the pain, which had not improved under hot compresses. In support of his claim that these attacks have no connexion with appendicitis Professor Moro records the case of a girl aged 14, where the colic was accompanied by tenderness over McBurney's point. Laparotomy was performed next day, when the appendix was found to be perfectly healthy. Professor Moro's publication has drawn an emphatic protest from Professor Küttner,[2] who considers the dissociation of umbilical colic from appendicitis a dangerous teaching. He records in detail six cases to prove his contention that umbilical colic may be due to the appendix, even when this is found at an operation to be apparently healthy. In four of these cases the appendix was unusually long and was attached by a mesentery of a spiral form. This arrangement, he argues, must favour volvulus of the appendix during peristalsis, and the spontaneous correction of this volvulus probably synchronises with the cessation of the pain. Again, small and soft fæcal concretions, slight kinking due to adhesions, or an abnormal insertion of the appendix may, as some of his cases show, also be responsible for the attacks. Even when these slight abnormalities are not found the attacks may yet be due to spasm of the appendix, and in support of this hypothesis he records the following case. A lad of nervous temperament, aged 15, had lately suffered from attacks of fainting. For a considerable time he had also been subject to violent attacks of abdominal pain, which would occur without apparent provocation, or after he had shaken his abdomen while laughing. They would quickly pass off without being localised to any particular area of the abdomen. Although objective signs of disease could not be detected, the appendix was suspected, and as the lad was much inconvenienced by the attacks laparotomy was performed. Close to the base of the appendix was an annular constriction, beyond which the appendix formed a spindle-like swelling. The appendix was removed, and was found to contain fæces. Its microscopic examination showed a perfectly normal condition. There was no inflammatory stricture. That the appendix was responsible for the attacks is evident, for they did not recur after the operation. The permanent cessation of the umbilical colic in the remaining five cases is the most convincing evidence in support of Professor Küttner's contention. Professor Moro[3] has replied to these statements by pointing out that his patient whose abdominal pain led to the removal of the appendix was not cured by the operation. The discussion between these authorities resolves itself into the question whether the "wait and see" or the "look and see" policy is the wiser, and it is clear that weighty arguments are available for both points of view.

"HELMINTHEMESIS."

THE vomiting or expulsion by the mouth of intestinal parasites is a rare occurrence. The parasite most commonly expelled is the ascaris lumbricoides, which is remarkable for its vagrant habits. Under the apt designation of "helminthemesis" Dr. David I. Macht has published in the *Johns Hopkins Hospital Bulletin* for April two cases, in one of which segments of tapeworm were vomited. Vomiting of tapeworm is so rare that Davaine in his great work ("Traité des Entozoaires") could collect only five cases. Dr. Macht's patient was a white woman, aged 21 years and married, who went to the dispensary of the Johns Hopkins Hospital on May 19th, 1913. She stated that in December, while in the early months of pregnancy, she was vomiting frequently. One day after violent retching she vomited a portion of tapeworm. She called her mother, who ran to her assistance and pulled a further and large segment of the worm out of her mouth. The fright caused miscarriage. Two days later she passed two long pieces of worm per rectum, and since then had been passing for half a year small segments. She complained chiefly of weakness and nervousness. She was given half-drachm doses of oleoresina aspidii, and two days later brought a jar full of tapeworm which proved to be tænia saginata. The head could not be found. In the other case a round worm was vomited. A farmer, aged 25 years, came to the dispensary complaining of indigestion, pains in the stomach, and vomiting of worms. In the past three months he had lost 15 lb. in weight in spite of a good appetite. For the past four weeks his appetite had been ravenous, and he vomited a number of times in the latter part of the day. Three weeks ago, after severe retching, he vomited a worm. Before that time he never noticed any worms in the stools, but he had since. He felt weak and complained of pains around the waist. On examination he looked thin and pale. The tongue was heavily coated and the breath was foul. The temperature was 100·5° F. and the pulse 120. He was given grain doses of santonin, and two days later brought a jar containing 10 or 12 full-sized specimens of ascaris lumbricoides. Dr. Macht has analysed all the cases of tape and round worm treated at the Johns Hopkins Dispensary in the last eight years. There were 65 of the former and nine of the latter. About two-thirds of the cases of tapeworm occurred in women, who were almost all under 40. Vomiting occurred in 7 per cent. of the tapeworm cases. Of the ascaris cases only one gave a history of vomiting.

THE BRUIT DE GALOP.

CLINICAL experience has attached considerable significance to this type of abnormal heart sound. It is usually of serious import. It has been called the *signum mali ominis*. Only lately, however, has any attempt been made to offer an explanation, not only of its cause, but also of the gravity of its meaning. The bruit de galop consists of a sharp doubling of the first sound—tă-tă, tā. It is, in reality, caused by a short sound appearing just before the first sound; that is, it is presystolic in time, and occurring as it does produces the double quality. This definite association with the first sound distinguishes it from the rhythm, also of galop quality, which is due to doubling of the second sound. This protodiastolic bruit de galop, common in mitral stenosis, is of entirely different significance. The bruit de galop is accepted as being produced by the strengthened systolic activity of the auricle, though the exact mechanism inducing it is a matter of some uncertainty. Some experiments are recorded by Offenbacher in the *Archiv für Experimentelle Pathologie und Pharmacologie* (1914, Band lxxvi., p. 1), which throw some light on the subject. The observations were made upon rabbits, the heart and pressure changes being recorded. They showed that strengthened auricular action occurs whenever there is a disproportion between the cardiac activity and the work which has to be done by the heart. Such disproportion, he was able to show, may arise when the heart is weakened by intravenous injections of solutions of magnesium sulphate; when the blood pressure is raised by compression of the aorta or the injection of adrenalin; by stimulation of the inhibitory nerves; or in the systole following the compensatory pause after an extrasystole. It is of interest to note that it is just these conditions, seen clinically, which favour the appearance of the bruit de galop; especially is this the case in chronic interstitial nephritis with failing heart. But this is not all. In this same clinical condition cardiac failure is especially prone to give rise to the type of pulse known as the pulsus alternans. In sudden death and street accidents in an age when these were even more frequent than at present. "When sudden death happens (see Hawes—'Address to the King and Parliament of Great Britain,' edit. 3) by accident in the public street, or other places on land, too often the consideration of inconvenience overcomes the dictates of humanity, and no friendly door is open to receive the body; or, if there is, the attendants are ignorant of their duty." Hurriedly called in, the medical man finds a scene of real confusion. If poor, the victim of the accident lies in the open street among "a croud." If the apparent corpse shows signs of prosperity, "it may perhaps be raised from the ground and placed on a shop floor." The medical man always has to regret the absence of "necessary as well as proper assistance." First aid was not then taught, and Hawes at this time became its pioneer. He delivered lectures and distributed pamphlets gratis on the modes of recovering persons from syncope, inebriety, trance, drowning, suffocation by the cord, or noxious vapours, intense cold or lightning, and on stillborn children and the effects of poisons, and on the certain signs of death. These lectures closed in 1782 with an adjudication of prize medals, offered by Dr. Hawes. The first gold medal was presented to Dr. Pearson, of Birmingham, on behalf of the Humane Society by Dr. Lettsom, Dr. Fothergill, and others, his being considered the best dissertation on the question, "Are there any positive signs of extinction of human life, independent of putrefaction? If so, what are they? Or, if there be not, is putrefaction a certain criterion of death?" The medal bore the name of Dr. Hawes, the donor, and the now famous motto, "Lateat scintillula forsan." The Humane Society was actually founded in 1774 through the joint efforts of Fothergill, Hawes, and Cogan. In 1784 the classical-looking receiving house was built near what was then known as the Serpentine River. It was chiefly designed for the purpose of restoring animation in those who had been "plunged into the contiguous stream." At the time of its erection it was considered without rival in Europe, and it remains to-day to remind a careless generation of the zealous philanthropy of the latter part of the eighteenth century—a philanthropy inspired by lofty motives, however fantastic or inadequate in its realisation. Dr. Hawes was typical of his age, a good talker, with a strong sense of humour which must have endeared him to Goldsmith. But it is for his characteristic public spiritedness that he will be remembered in the history of his time.

TROPICAL DISEASES RESEARCH FUND.

THE report of the advisory committee for the Tropical Diseases Research Fund for the year 1913 has just been presented to Parliament and is now issued as a Blue-book (Cd. 7261)[1] by the Colonial Office. The committee, which was constituted by the Secretary of State for the Colonies in July, 1904, is now composed as follows: The Right Hon. Sir J. West Ridgway, chairman; Sir Thomas Barlow, Sir John Rose Bradford, Sir David Bruce, Sir R. Havelock Charles, Mr. F. H. Drake, Sir Patrick Manson, Mr. H. J. Read, Sir Ronald Ross, and Mr. J. A. C. Tilley, with Mr. A. B. Keith as secretary. The late Sir A. M. Branfoot, who had been a representative of the India Office from the first, resigned from the committee before this report was prepared, and his colleagues place on record their high appreciation of his constant interest and the services which he rendered. The report itself occupies barely two pages, the rest of the volume of 240 foolscap pages being devoted to detailed appendices. The first of the six appendices consists of reports on anti-malarial measures in the Crown colonies, protectorates, &c.; the second is the report of the professor of protozoology in the University of London, Professor E. A. Minchin, for the year ended June, 1913; the third is the report for 1913 on the work of the Quick Laboratory, Cambridge, by the director, Professor G. H. F. Nuttall; the fourth comprises reports from the London School of Tropical Medicine; the fifth contains corresponding reports of the year's investigations at the Liverpool School of Tropical Medicine; while the sixth appendix contains reports on work done in various colonial laboratories. These appendices include a large amount of valuable information from a large number of sources, and further reference will be made in these columns to the results of some of the more important investigations which are detailed therein.

THE RELATION OF APPENDICITIS TO UMBILICAL COLIC IN CHILDREN.

A CONDITION has lately been described as "*relapsing umbilical colic*" by Professor E. Moro,[1] of Heidelberg. He points out that it is not infrequent in children over 4 years, that it recurs at regular intervals, and that the patients are, as a rule, neuropathic. He considers the attacks have no connexion with appendicitis, and he gives the following account of their most salient features. The child suddenly becomes pale and complains of violent pain in the region of the umbilicus, or between it and the ensiform process. The pain begins without apparent provocation, and frequently occurs while the child is at play, making him press both hands upon his abdomen. An attack may also occur while he is walking, sitting at table, or eating, but never in school. Such an attack may only last a couple of minutes or several hours, and it invariably recurs sooner or later. Not infrequently the attacks recur at regular intervals of two or three months, and they are seldom accompanied by vomiting. In three cases in which this did occur it was periodic or acetonæmic. The temperature is never very high, whereas a subfebrile temperature of 100·4° F. in the rectum is common. In 15 out of 18 cases the patients suffered from constipation, which was frequently accompanied by meteorism and rigidity of the abdominal wall. The parents would sometimes state that castor oil or an enema had at once relieved the pain, which had not improved under hot compresses. In support of his claim that these attacks have no connexion with appendicitis Professor Moro records the case of a girl aged 14, where the colic was accompanied by tenderness over McBurney's point. Laparotomy was performed next day, when the appendix was found to be perfectly healthy. Professor Moro's publication has drawn an emphatic protest from Professor Küttner,[2] who considers the dissociation of umbilical colic from appendicitis a dangerous teaching. He records in detail six cases to prove his contention that umbilical colic may be due to the appendix, even when this is found at an operation to be apparently healthy. In four of these cases the appendix was unusually long and was attached by a mesentery of a spiral form. This arrangement, he argues, must favour volvulus of the appendix during peristalsis, and the spontaneous correction of this volvulus probably synchronises with the cessation of the pain. Again, small and soft fæcal concretions, slight kinking due to adhesions, or an abnormal insertion of the appendix may, as some of his cases show, also be responsible for the attacks. Even when these slight abnormalities are not found the attacks may yet be due to spasm of the appendix, and in support of this hypothesis he records the following case. A lad of nervous temperament, aged 15, had lately suffered from attacks of fainting. For a considerable time he had also been subject to violent attacks of abdominal pain, which would occur without apparent provocation, or after he had shaken his abdomen while laughing. They would quickly pass off without being localised to any particular area of the abdomen. Although objective signs of disease could not be detected, the appendix was suspected, and as the lad was much inconvenienced by the attacks laparotomy was performed. Close to the base of the appendix was an annular constriction, beyond which the appendix formed a spindle-like swelling. The appendix was removed, and was found to contain fæces. Its microscopic examination showed a perfectly normal condition. There was no inflammatory stricture. That the appendix was responsible for the attacks is evident, for they did not recur after the operation. The permanent cessation of the umbilical colic in the remaining five cases is the most convincing evidence in support of Professor Küttner's contention. Professor Moro[3] has replied to these statements by pointing out that his patient whose abdominal pain led to the removal of the appendix was not cured by the operation. The discussion between these authorities resolves itself into the question whether the "wait and see" or the "look and see" policy is the wiser, and it is clear that weighty arguments are available for both points of view.

"HELMINTHEMESIS."

THE vomiting or expulsion by the mouth of intestinal parasites is a rare occurrence. The parasite most commonly expelled is the ascaris lumbricoides, which is remarkable for its vagrant habits. Under the apt designation of "helminthemesis" Dr. David I. Macht has published in the *Johns Hopkins Hospital Bulletin* for April two cases, in one of which segments of tapeworm were vomited. Vomiting of tapeworm is so rare that Davaine in his great work ("Traité des Entozoaires") could collect only five cases. Dr. Macht's patient was a white woman, aged 21 years and married, who went to the dispensary of the Johns Hopkins Hospital on May 19th, 1913. She stated that in December, while in the early months of pregnancy, she was vomiting frequently. One day after violent retching she vomited a portion of tapeworm. She called her mother, who ran to her assistance and pulled a further and large segment of the worm out of her mouth. The fright caused miscarriage. Two days later she passed two long pieces of worm per rectum, and since then had been passing for half a year small segments. She complained chiefly of weakness and nervousness. She was given half-drachm doses of oleoresina aspidii, and two days later brought a jar full of tapeworm which proved to be tænia saginata. The head could not be found. In the other case a round worm was vomited. A farmer, aged 25 years, came to the dispensary complaining of indigestion, pains in the stomach, and vomiting of worms. In the past three months he had lost 15 lb. in weight in spite of a good appetite. For the past four weeks his appetite had been ravenous, and he vomited a number of times in the latter part of the day. Three weeks ago, after severe retching, he vomited a worm. Before that time he never noticed any worms in the stools, but he had since. He felt weak and complained of pains around the waist. On examination he looked thin and pale. The tongue was heavily coated and the breath was foul. The temperature was 100·5° F. and the pulse 120. He was given grain doses of santonin, and two days later brought a jar containing 10 or 12 full-sized specimens of ascaris lumbricoides. Dr. Macht has analysed all the cases of tape and round worm treated at the Johns Hopkins Dispensary in the last eight years. There were 65 of the former and nine of the latter. About two-thirds of the cases of tapeworm occurred in women, who were almost all under 40. Vomiting occurred in 7 per cent. of the tapeworm cases. Of the ascaris cases only one gave a history of vomiting.

THE BRUIT DE GALOP.

CLINICAL experience has attached considerable significance to this type of abnormal heart sound. It is usually of serious import. It has been called the *signum mali ominis*. Only lately, however, has any attempt been made to offer an explanation, not only of its cause, but also of the gravity of its meaning. The bruit de galop consists of a sharp doubling of the first sound—tă-tă, tā. It is, in reality, caused by a short sound appearing just before the first sound; that is, it is presystolic in time, and occurring as it does produces the double quality. This definite association with the first sound distinguishes it from the rhythm, also of galop quality, which is due to doubling of the second sound. This protodiastolic bruit de galop, common in mitral stenosis, is of entirely different significance. The bruit de galop is accepted as being produced by the strengthened systolic activity of the auricle, though the exact mechanism inducing it is a matter of some uncertainty. Some experiments are recorded by Offenbacher in the *Archiv für Experimentelle Pathologie und Pharmacologie* (1914, Band lxxvi., p. 1), which throw some light on the subject. The observations were made upon rabbits, the heart and pressure changes being recorded. They showed that strengthened auricular action occurs whenever there is a disproportion between the cardiac activity and the work which has to be done by the heart. Such disproportion, he was able to show, may arise when the heart is weakened by intravenous injections of solutions of magnesium sulphate; when the blood pressure is raised by compression of the aorta or the injection of adrenalin; by stimulation of the inhibitory nerves; or in the systole following the compensatory pause after an extrasystole. It is of interest to note that it is just these conditions, seen clinically, which favour the appearance of the bruit de galop: especially is this the case in chronic interstitial nephritis with failing heart. But this is not all. In this same clinical condition cardiac failure is especially prone to give rise to the type of pulse known as the pulsus alternans In this type of pulse large and small contractions alternate in regular succession. Both auricle and ventricle may participate, and it has been noted that the large auricular contraction may coincide with the small ventricular beat. Such a condition, however explained, reveals an exaggerated auricular action with weakened ventricular force, and presents an important analogy to the more sustained strengthened auricular action, apparently excited by weakened ventricular force, and associated with the bruit de galop. Both the bruit de galop, and probably the pulsus alternans, are caused by weakened ventricular action; both have on independent lines been held to be of grave significance; and now it seems that we have a rational explanation of both, and incidentally we find exact corroboration of facts which were clinically noted long before explanation could be offered.

GASTRIC TETANY.

THE pathogeny of this condition appears to remain as obscure as it was when Kussmaul first directed attention to it in 1869. It was to be expected, perhaps, that, under the later and still dominant school of thought which seeks explanation for most pathological conditions in infection, the infective origin of gastric tetany should be suggested. Others, who have studied the condition very fully, believe that it may be due to absorption of stagnant contents of a dilated stomach which poisons the nerve centres and thereby increases reflex irritation. Such theories, however, still leave the pathogeny a *terra incognita*. The symptoms of gastric tetany are striking. There is usually a prolonged history of dyspepsia; the signs may strongly point to gastric or duodenal ulceration; still more often is there evidence of dilatation of the stomach, for which perhaps lavage has been industriously carried out. The tetany itself is abrupt in onset. There occurs pain of crampy character starting in the stomach. This is soon associated with spasms of the muscles of the extremities, especially the hands and feet. The fingers are usually flexed at the metacarpo-phalangeal joint and extended at the distal joints —the "accoucheur's hand." The spasms may extend to the larger limb muscles, and even involve the face. The general irritability of the musculature is often so enhanced that small local stimuli may induce a spasmodic condition of groups of muscles; in this relation, Chvostek's sign is familiar. In severe cases the onset of the symptoms may resemble a convulsion; there is, however, no loss of consciousness, and the peculiar distribution of the spasms is diagnostic. The treatment may be medical or surgical; its objective is the stomach. A dilated stomach is the rule, and its cause is usually to be found in pyloric or duodenal ulceration. There are, however, exceptions. Frequent washing out of the stomach is of much assistance, but operative measures offer a more hopeful prognosis. Following a gastro-enterostomy recovery may be complete, though not in every case. In an instance of gastric tetany described by Rodman (W. L.) in the *Journal of the American Medical Association* (1914, Vol. LXII., p. 590) the spasms followed operative treatment for duodenal ulcer associated with gastric dilatation. Previous to operation no such symptoms had been present. Recovery eventually followed. This writer emphasises the failure of medical treatment for gastric tetany, but at the same time he deprecates too optimistic a view being taken of the success of surgical intervention. This view applies especially to those comparatively rare cases in which the spasms involve the muscles of respiration and the larynx. Asphyxia may ensue, and there is little hope of cure. General treatment should be directed to lessening the quantity of those substances in the dietary which favour fermentation.

A MONUMENT TO VESALIUS.

IN August next there will be erected among the wave-swept rocks of the island of Zante a monument to the memory of Vesalius, one of the great pioneers of modern surgery. The occasion will be the quatercentenary of the birth of Vesalius, who perished miserably on Zante on Oct. 15th, 1564, after being shipwrecked as he was returning from the Holy Land, whither he had made a pilgrimage in penance. The reason is somewhat obscure, but it is said to have been in consequence of his having, probably unwittingly, made a necropsy on a Spaniard who proved still to have been alive when the necropsy was begun. Dr. Tricot, who has taken the lead in securing this belated tribute on behalf of Belgium to one of her greatest sons, gave to his French colleagues at the Sorbonne the other day an interesting, if gruesome, account of the youthful enthusiasm of Vesalius, which led him when still a boy to feast his eyes, not upon the delicacies of the tuck-shop, but upon the display of meat and tripe on the butchers' stalls. His delight at an early age was to procure a bullock's heart or a sheep's kidney and to carry it home in triumph for dissection, and we are told that while his father, apothecary to Charles V., encouraged his pursuit of anatomical knowledge, his mother, not best pleased with the turn things were taking in the home, grumbled, but provided him with a bib and tucked up his sleeves to prevent disaster to his clothes. Then the time came when the young student must needs work upon the human subject, and nightly excursions to the place where the bodies of criminals were left to be devoured by scavenging dogs provided at great personal risk material whose examination made him, at an age when he was still learning his Latin accidence at school, the best informed anatomist in Europe. He entered the University of Louvain at an early age, proceeding to Paris in 1533, where he continued his grim search for truth among the human débris by the Montfaucon gibbet. In 1536 he returned to Louvain, as a teacher of his subject. He then went to Padua, where he became Doctor of Medicine, and was appointed in 1537 Professor of Surgery with the right to teach anatomy. He also conducted courses in anatomy at Bologna and Pisa. Vesalius was offered the chair of anatomy in Pisa, where he had conducted public dissections, but preferring the office of Archiatros to the Emperor Charles V. of Spain he went to Madrid, where he served that monarch and his son for 20 years—viz., until 1564—when he went on his ill-fated pilgrimage. Having thus reached certainty by long and accurate study at first hand, Vesalius waged wordy warfare with the Galenists, whom he effectually answered in his epoch-making "De Corporis Humani Fabrica Libri Septem" (1543) in which the old theories were confuted by practical experiment conducted under conditions of almost insuperable difficulty.

THE PREVENTION OF LIFE-WASTE.

ON Dec. 29th last there was incorporated in the City of New York a "Life Extension Institute," having for its aim the lengthening of human life and the safeguarding and increase of individual human efficiency. This end it proposes to achieve by the appointment throughout the land of expert medical examiners, with fully equipped clinical laboratories in all the larger towns, who will periodically examine the physical condition of its own policy-holders, of all the policy-holders of such life insurance companies as contract with it to do so, and for a small fee of any person not embraced in either of these classes, who may desire it. Schools, industrial establishments, and other associations will also be contracted with, and its aid will be further afforded in coöperation with the anti-tuberculosis, social hygiene, eugenics, and similar movements, and with the health authorities. It is thought that by this means "impairments" in the human machinery will be systematically detected while they are still remediable, and the damaged individual directed before it is too late to seek the aid of his medical attendant, who will be furnished with the collaborated findings of the institute's experts. The "Hygiene Reference Board" of the institute, which is to consist of 100 leading experts on various subjects pertaining to health, contains many names well known to the medical profession at large, among whom may be mentioned Surgeon-General Gorgas, the sanitarian of Havana and the Panama Canal Zone, Dr. William J. Mayo, Professor William H. Welch of Johns Hopkins University, Dr. Harvey Wiley, whose name is associated with the pure food laws in the United States, Professor Chittenden, of Yale, and others. The individual will benefit by having his attention called to beginning defects while there is yet time to repair the damage. The medical practitioner will find many of his patients directed to seek his care long before they would otherwise have done so, with the advantage of receiving a carefully collaborated physical report by various experts in their respective lines to work on. The insurance companies will have their losses from life-waste reduced as the fire insurance companies have long reduced their losses from fire-waste. It is further hoped that the vast material accumulated by the Hygiene Reference Board may in course of time enable it to furnish data whereby many disputed points in personal hygiene may ultimately be cleared up. The experiment will be watched in this country with interest: the prophecies of its future work, which we have set out, show its scope to be indeed comprehensive.

TRAUMATIC RUPTURE OF THE HEART.

IN the *Journal of the American Medical Association* of Feb. 28th Dr. B. J. O'Neill has reported a case of a very rare accident—traumatic rupture of the heart. A schoolboy, aged 9 years, while playing was set on by some older boys, who knocked him down and jumped on him. He walked home complaining of pain in the left groin, remained in bed two days, and then got up and about for four days, still complaining of pain in the left groin and hip. On the seventh day he was taken a distance of 30 miles by train to Dr. O'Neill, still complaining of the same symptoms. At no time did he complain of pain in any other part. He walked from the station to the office. Examination showed a well-developed boy walking with a decided limp and evidently in considerable pain. Slight redness and swelling over the left saphenous opening was discovered. There was considerable limitation of the movements of abduction and rotation of the left thigh. No examination of the chest was made. The boy was sent to hospital, where a skiagram of the hip and pelvis was taken and showed nothing abnormal. Hot fomentations were applied to the hæmatoma in the groin. The temperature was 98·6° F., the pulse was 102 and regular, and the respirations were 25. He rested comfortably until about 12 hours after admission. Then he suddenly collapsed, the pulse and respiration became very rapid, and he died in an hour. At the necropsy the pericardium was found bulging forwards, very tense and full. It contained about 500 c.c. of fresh blood and about 200 grammes of dark clotted blood. At the auriculo-ventricular junction on the left side was a perforating slit about 3 millimetres long above the middle of the anterior leaf of the mitral valve. The myocardium and valves were normal. Evidently the heart was ruptured at the time the boy was jumped on, and some hæmorrhage took place into the pericardium, which was followed by sealing of the perforation with clot. Some movement probably dislodged this clot, and death resulted from hæmorrhage into the pericardium. It is remarkable that the boy was up and about for four days with only the clot sealing the opening. The case illustrates the lesson which will never cease to require enforcing—the necessity for complete examination of a patient. Dr. O'Neill thinks that had this been done at least an approximate diagnosis might have been made.

THE ORGANISM OF EPIDEMIC POLIOMYELITIS.

THE discovery that the human disease epidemic poliomyelitis could be transmitted to monkeys opened the way to accurate experimental research on this infection, and many valuable papers have since been written on this subject. The work done at the Rockefeller Institute in New York by Professor Flexner, with the assistance of Dr. Noguchi, Dr. Paul Clark, Dr. Harold Amoss, and Dr. F. R. Fraser, has been largely recorded in the *Journal of Experimental Medicine*, and it may be useful to summarise the results which they have obtained. The micro-organism which is the infective agent has now been cultivated on artificial media, the method used being that devised by Noguchi for the cultivation of spirochætæ, human ascitic fluid being the basis of the medium, with the addition of small pieces of solid sterile tissue, the culture being kept anaerobic by covering it with a layer of paraffin oil. Thus grown the organisms appear as minute globular bodies arranged in pairs, chains, and clusters, and they can also be demonstrated in the infected tissues by means of appropriate dyes. Reinoculation of susceptible animals with the cultures has been effected in one or two instances, thus fulfilling Koch's second canon, but failures often occur owing to rapid loss of virulence in the organisms when introduced to artificial conditions. Their exact biological position has not yet been determined—whether they should be classed with the bacteria or with the mysterious group of chlamydozoa. Their minute size enables them to pass through the pores of a Berkefeld filter. Within the body the organisms are visible not only in the spinal cord, but also in the brain, vertebral and Gasserian ganglia, and abdominal sympathetic. Poliomyelitis is thus not a special disease of the anterior cornual cells as was previously supposed, but a general infection of the central nervous system. The lesions produced are both interstitial and parenchymatous. Post-mortem multiplication of the parasites can be obtained by incubating pieces of infected brain tissue. The virus derived from a human source can be rendered more pathogenic for monkeys by passage through a series of these animals, but after a time this virulence tends to fall again. The channel of infection is not thoroughly ascertained. Flexner favours ingress by the lymphatics of the nasopharynx. Direct injection into the spinal theca may induce infection, but the virus then passes rapidly out into the blood stream, where it is apparently neutralised or destroyed. The blood is not often found to be infective, and direct injection into the circulation is an uncertain mode of inducing the disease. From the blood the virus seems incapable, as a rule, of entering the cerebro-spinal fluid; indeed, the interchange of constituents between this fluid and the blood seems to be usually minimal, as in the case of patients treated with salvarsan in whom injection of their own serum into the spinal canal has been practised as a means of introducing the remedy locally and thus combating syphilitic lesions of the central nervous system. Attempts to transmit poliomyelitis by the bite of the fly, stomoxys, were unsuccessful, and in view of the general features of the infection insect transmission does not appear a probable hypothesis.

WE regret to record the death of Dr. Thomas Frederick Pearse, late Medical Officer of Health of Calcutta, who died at Torquay on April 14th. Dr. Pearse was for many years one of the special correspondents of THE LANCET.

Mr. Herbert Jones, D.P.H. Cantab, medical officer of health for the Herefordshire Sanitary Districts, has been elected President of the Society of Medical Officers of Health immediately upon the conclusion of his term of office as secretary, a proof of the recognition by the society of his intimate knowledge of their views and his untiring industry in forwarding them. During the 60 years of the existence of the society the secretary has on six previous occasions attained to the chair, the instances being the late Sir George Buchanan, the late Sir Thomas Stevenson, the late Professor Corfield, Sir Shirley Murphy, Dr. Edward Seaton, and the late Dr. J. F. J. Sykes.

INAUGURATION OF THE NEW UNIVERSITY BUILDINGS AT ZÜRICH.—On April 18th the new university buildings of Zürich, erected at a cost of £240,000, were inaugurated. They are situated in an elevated position near the various hospitals and the Federal polytechnic school, and command a magnificent view from the terraces and the tower. They are to serve as lecture house and also contain the biological institute, while the new building for pharmacology and hygiene is situated at a short distance. The Federal Government, the Cantonal Government, and several scores of delegates from all parts of Europe attended the opening ceremony, which commenced with a musical cantata, the music being composed by Dr. Hegar. All the Swiss universities, 21 German universities, and the universities of Paris, Oxford, and Cambridge sent delegates. Dr. Keller and Dr. Locher spoke as representatives of the Cantonal Government, and Professor Egger as rector of the university. The speech of Dr. R. W. Macan, Master of University College, Oxford, was especially applauded. In the evening a banquet for 800 guests took place. On the 19th the guests made a trip down the lake in glorious weather. On the 20th the guilds of Zürich took part in a historical pageant representing the development of science from ancient to modern times.

SOCIETY AND SEX PROBLEMS.

THE intricate problem of the regulation of sex relationship in modern society is showing signs of a rapid progress through the normal evolution of all social problems out of the sphere of ethics into the sphere of sociology. The primitive state in which men at first approach all such problems is the ethical and emotional. They are filled with a repugnance, say, to prostitution, and they loudly demand measures for its regulation or suppression without realising the underlying conditions. The failure of these measures, where obtained, after a while leads up to the second stage. The condition of emotional animosity gives way to the spirit of scientific inquiry; the primitive axiom, "Something must be done," is succeeded by a desire for a knowledge of the actual facts and the collection of information from all sources that are open: the problem, in short, passes from the sphere of ethics to the sphere of sociology; from the sphere of emotional but ignorant action to the sphere of intellectual inquiry. It is only later that the social problem finally passes back once more to the sphere of ethics; but the action taken is no longer blind and emotional, it is guided by the results obtained from the impassive sociological investigations. Whereas the problem of marriage is still restricted within the first or ethical stage, the problem of prostitution has now fairly emerged into the colder air of sociology.

The Problem of Prostitution.

The pioneer work of Parent-Duchâtelet has paved the way to a number of modern investigations of great interest and value. Of these the most recent are the remarkable publications of the New York Bureau of Social Hygiene, formed under the auspices of Mr. John D. Rockefeller, jun. In the two volumes now published,[1] Mr. George Kneeland describes the present condition of prostitution in New York, while Mr. Abraham Flexner deals with prostitution in Europe.[2] Mr. Flexner devotes his attention mainly to the existing methods of administration and police supervision; while Mr. Kneeland, on the other hand, deals chiefly with the various forms, the resorts and the *personnel* of prostitutes and of the trade growing up around them.

We note with interest the tendency of both these, as of most other modern writers, to regard prostitution more as a result of environment than of congenital wickedness or stupidity. Since Lombroso formulated his theory of the *delinquente nato* there has been a steady progress of opinion in the opposite direction. Mr. Kneeland and Mr. Flexner do indeed affirm some connexion between prostitution and congenital weakness, though a connexion far slighter and more elusive than that postulated too crudely by the Italian criminologist. But it may be doubted whether the trend of opinion away from Lombroso has yet reached its goal. The prostitutes studied in the investigations under notice are very largely those under the supervision of the police, and those who live in bordels and hand more than half their profits to the "Madame" or bordel-keeper. Now it may be safely affirmed that these are the weakest and stupidest of their class, and we can no more infer from them a general feeble-mindedness among prostitutes than we can obtain statistics of tuberculosis from an exclusive study of the population of hospitals. Deeply as congenital differences are rooted among our people, they are altogether obscured by the adventitious circumstances of birth and money. The master is not necessarily or even probably better than his servant, except in so far as he is better educated. And so, too, the young man in search of pleasure wreaks his sensuality upon the body of a woman who, according to an almost even probability, is of higher natural endowments than himself, and who owes her position purely to those economic forces which inundate and overwhelm the minor distinctions of nature. Whatever theory we form of the causes of prostitution, it must often happen that the woman, who under more favourable conditions might have been a valuable ornament to society, is butchered alive by successions of men who, but for the accident of birth, would have been gaol-birds.

[2] Prostitution in Europe. By Abraham Flexner. Introduction by John D. Rockefeller, jun. London: Grant Richards. 1914. Pp. 455. 7s. 6d. net.

Present Conditions.

The disclosure made by the American writers of the conditions under which the inferior prostitute lives is indeed startling. Instances are recorded where a woman receives over 50 men in one day; the city physician of Rome vouched for a case of 60 visitors; the mayor of Bordeaux reported to the French commission one woman who had received 82 clients in a single day. In Chicago, at a certain vice-resort, women were found to average 15 men a day for nearly two years. In New York one woman served more than 2000 men in a period of six months. In one house, where the fee charged is 50 cents,—

> A large wooden bench was placed against the wall of the receiving parlour. Business was very brisk at the time the investigator entered. The bench was full of customers crowded close together, while others, who could not be accommodated with seats, stood about the room. At the foot of the stairs which led to the bedrooms above a man was stationed. Every time a visitor came groping his way down the stairs the businesslike and aggressive announcer would cry out "Next!" At the word the man sitting on the end of the bench nearest the stairs arose and passed up. As he did so the men on the bench moved along and one of the men who were standing took the vacant seat.

In Europe the tendency for years past has been to suppress bordels (i.e., licensed and registered brothels). In Paris no new bordels are licensed; and the decline in number of the old ones is remarkable. In 1841 there were 235 bordels; in 1888 there were only 69; while in 1903 there were 47. This decline appears to be due to several causes, one of which is the intimate connexion of bordels with the white slave traffic. But the bordel is essentially a mediæval institution, unsuited in many ways to modern conditions. The women, however low their discrimination, cannot but dislike a contract under which they resign more than half their earnings to the manager, and are obliged, not only to accept every client that presents himself, but to submit themselves to any kind of outrage that his perverted whims may require of them. On the other hand, the men dislike an institution in which every mode of extracting their money is resorted to; and, moreover, they are beginning to learn that bordels do not afford a guarantee against the acquisition of disease.

The Case against Regulation.

Students of prostitution at the present day are divided into the two opposing camps of *regulationists* and *abolitionists*. The former school regard prostitution as a necessary evil, and demand that it should be controlled by Government; that its regular followers should be medically examined at frequent intervals, and receive licences to practise their calling so long as they are not found to be diseased. This is the system in operation in most continental countries. The abolitionists, on the contrary, demand the cessation, not of prostitution indeed, for that is obviously impossible, but of all regulation or recognition by the State of prostitution as a trade. This is the British view, and it is the view to which educated opinion is strongly leaning at the present time. The arguments by which abolition of regulation is defended are wholly different from those which led to the repeal of the Contagious Diseases Acts in the "eighties." They rest chiefly upon the fact that regulation after a long and careful trial has turned out to be a failure. Mr. Flexner, who is an ardent abolitionist, goes so far even as to affirm that regulation has probably increased rather than diminished the amount of venereal disease, on the ground that the protection supposed to be afforded is illusory, whereas the fancied security increases the volume of the prostitute's business. The comparatively small number of prostitutes who are isolated in continental countries on account of disease is itself sufficiently striking to show that such methods cannot seriously affect the problem of venereal disease; nor does anyone suggest that there is less disease in such countries than there is in abolitionist countries. Yet Mr. Flexner does perhaps put his case too high; it would seem, even on the basis of his own statistics, that regulation does have some slight effect in the reduction of disease, though an effect far from commensurable with the numerous drawbacks of the method. Mr. Flexner gives an account of the methods of medical examination in Paris.

> All day long a dismal procession of groups of abandoned women file into the rudely equipped rooms in which two physicians ply their repellent task perfunctorily. A line is formed; with open jaws and protruding tongue they march rapidly past. The doctor uses one spatula for all, wiping it hastily on a soiled towel from time to time. This finished, the same group in quick succession ascends two surgical chairs to permit a cursory vaginal inspection. ...... Of the two physicians employed on the occasion of one of my visits, one used a rubber glove, the other a rubber finger —in both cases the same for all; though wiped on a towel from time to time, neither was changed or cleansed. On one occasion I observed one of the physicians examine 25 or 30 girls without changing, washing, or wiping the rubber fingers he wore; and a number of those examined were adjudged "diseased." ...... The inspections consumed from 15 to 30 seconds each.

At Paris, moreover, the registered woman has no legal rights and is entirely in the hands of the police. On a complaint being made by a "morals patrolman" against her, the police inspector himself pronounces sentence, nor is she allowed an attorney to defend her or witnesses to attest her innocence of the alleged offence; and she has no appeal to any regularly constituted court of justice. Regulation inevitably tends to keep women in the business who might otherwise escape from it. For prostitution is not, as commonly supposed, a permanent trade. Its *personnel* changes quickly from year to year. Girls go in at a certain age, and after a time drift into other employments—become servants, factory girls, waitresses, or sometimes marry. It is a "blind alley" occupation, in the sense that profits rapidly fall off after a certain age, and in London there seem to be few who persist to the last stage. Still, alas, we have all seen them worn and decrepit at the corners of shabby streets, eking out a miserable and precarious livelihood by selling themselves for pence.

Social, Economic and Medical Aspects.

The day of regulation is over, as anything like a general policy, despite the salutary effects that might follow upon it, if very carefully worked in special communities. Now the social problem in the matter of prostitution is to decide what particular type of so-called abolition shall be preferred, and how far the police shall interfere with the prostitute. Indiscriminate and absolute repression is impossible both in practice and in theory. The police cannot afford to make a mistake: public opinion will not for a moment tolerate the arrest of a woman as a prostitute who turns out after all not to be a prostitute. Since the police cannot take action, even on strong suspicion, it is obvious that a very large proportion of the women must be beyond their reach. Public opinion, moreover, will not permit any class to be harried to more than a certain extent. The existence of a huge and vehement demand among men is a fact which no one questions; and so long as this demand exists, there will remain an element in public sentiment which will safeguard the continued existence of prostitution, though its threefold evils—the social, the economic, and the medical—are manifest.

The social evil has been more or less outlined above; it centres about the ruined lives of numberless young women who are condemned to an existence of servitude and degradation. But here we must rigorously resist sentimentalism, while not withholding pity. We must estimate what many of them have lost in losing their virtue. It must be remembered that these women, mostly drawn from the lowest classes, would in the majority of cases lead lives of little attraction in any circumstances. The hard and unremitting toil of their normal lives does not offer any great advantage over the degradation of their adopted lives; they are in any case the unfortunates of society, condemned to the dirty work which others more fortunate can avoid. Nor is the moral degradation so complete as is commonly supposed. The charity of prostitutes towards one another is famous; they are capable of falling recklessly in love, though often with the most infamous of men; and no one susceptible of the highest passion of love can be held to be altogether corrupt or abandoned.

On the economic side the evil of prostitution consists in the removal from productive employment of a large number of active-bodied females. The economic argument assumes that the services rendered by prostitutes to society, and so heavily paid for by society, yield back nothing. That this is the case appears patent to all who are in the ignorantly ethical state of mind to which allusion has been made. The physiologist and sociologist are likely to hesitate long before expressing a decided opinion. A nation of "virgin" men may or may not be superior to a more ordinary nation; we have no evidence to found an induction upon. We know, however, that all the greatest and most successful and virile nations of the world support large armies of prostitutes; and we know from the law of natural selection that the organic structures, whether of an individual or of a society, are evolved to fulfil some vital need, however little we may perceive the nature of that need. If prostitution were a sheer drain on society, if the vast economic burden entailed by it upon society were balanced by no compensating circumstance, then every biological analogy suggests that all societies trafficking in prostitution must long ago have been wiped out by the ruthless operation of natural selection. We should expect to find that the successful nations were those free from the economic waste and the moral degradation involved by prostitution. But we find the opposite; and we shall perhaps see in this circumstance a reason to hesitate before we add to our condemnation of this unhappy class the charge of being utterly and uselessly parasitic upon the community.

The third evil of prostitution—the propagation of disease—is the one that strikes the public with the greatest force. We need not expatiate upon it in these columns. All medical men know its terrible realities, and rejoice to think that, although pathology is revealing to us an increasing range of the mischief, therapeutics, including, of course, prophylaxis, have made such strides that syphilis may succumb to medical attack long before any unwieldy instruments of social reorganisation can be brought into effective use.

There seems to be in the great centres of civilisation a slight decline in prostitution, while in our own country it is commonly accepted that in all the better classes of society morals are somewhat looser than they were in the Victorian age. The wider general knowledge of preventives of conception would probably tend to this result, and may account for the alleged decline of prostitution; the demands of men, being met to a larger extent by society at large, become less dependent on a specialised class. And Government suppression of that class might accelerate the progress of the modern tendencies. If these observations are speculative they indicate at all events the fact that long study and thought have still to be spent on the subject by the scientific sociologist before it is ripe to be handed back to the active propagandism of reformers and politicians.

Works on Sex Problems.

The "Questions of Sex" series, issued by the National Council of Public Morals, is admirably adapted to the purpose which the council has in view. Dr. Mary Scharlieb[3] deals with the subject on conventional lines, and her book may confidently be recommended to all young people who require information, supplied in good taste and not too much of it, on the subject of sex. Mr. Walter Heape's book[4] is admirably written and should be widely read; it is the production of an experienced man of the world. Mr. Heape holds up the banner of morality with dignity, ardour, and conviction; his book is precisely adapted to the requirements of those to whom it is addressed. Yet we seem to read occasionally between the lines that the author knows much more and would like to have said much more than could fittingly be introduced into such a book as the present. He appears at times to be somewhat cramped by his platform: a writer who might well make important contributions to the sociological and ethical aspects of the sex problem is necessarily writing below his full strength when he produces text-books of information for young people. The National Council of Public Morals are fortunate in having secured his services; few modern writers appear so well equipped to raise the subject of sex-relationship from the sphere of blind ethics to that of an inductive science. Setting aside theories, the problem centres round the following fact: that on the continent all men, and in this country a very large number of men, indulge in promiscuous intercourse at some period of their lives. Unmarried women, on the other hand, are divided into two profoundly distinct classes, one of which is brutalised by venal excess and the other condemned to total abstinence—a condition which Mr. Heape regards as pathological and even dangerous to society. When once this problem has been removed from the sphere of ignorant bigotry, and can be discussed (as in the books now under review) in a spirit of true knowledge and philosophic calm, it may still be possible to escape from the disharmony which has for so many ages divided and weakened civilised societies.

A recent addition to the Contemporary Science Series, written by Professor Robert Michels,[5] professor of political economy and statistics at Basle, and an honorary professor of law in the University of Turin, deals freely and rather romantically with many of the problems of sex as they present themselves conjugally and preconjugally. The book is readable, and the illustrative cases are frequently drawn from the works of well-known poets and novelists. The aim of the author, in his own words, is to provide "a meeting-place of a small group of selected and important problems which press themselves upon our attention and urgently demand solution." He groups the problems under the following headings—(1) General Borderland Problems of the Erotic Life; (2) Borderland Problems of the Extraconjugal Erotic Life; (3) Preconjugal Borderland Problems; and (4) Borderland Problems of the Conjugal Sexual Life, and states them, without furnishing dogmatic replies. The scientific attitude of the work is not insisted upon, but it is unsuitable for anything like general circulation.

The work of Dr. Magnus Hirschfeld[6] on homosexuality provides scope for reflection to those who call, with little knowledge, for the suppression of prostitution. Dr. Hirschfeld seems to us greatly to exaggerate the extent to which sexual perversion prevails in modern society, but he has himself seen so much that his knowledge must be received with respect. Still, where statistics are entirely and inevitably wanting, there must ever be a tendency to generalise too hastily from the cases brought before the specialist. The prevailing opinion seems to be that this particular sort of crime among men is rare in this country. Among women, where the offence is not illegal, it is currently reported to be somewhat common among the luxurious and idle classes, and the scandal of London bandies freely the names of those in high strata of society said to be thus addicted. The distribution of such nauseous talk has been, and is, in the highest degree mischievous.

PUBLIC HEALTH OF LONDON IN 1912.

(Concluded from p. 1159.)

PART II.—EDUCATION.

THE decree of the London County Council combining under one head the central public health administration, the school medical service, and the arrangements for the medical treatment of defectives has, as already seen, involved the complete reconstruction of the public health department. From the report before us it will be realised, not only that much has been already accomplished in this direction, but that more remains to be done, the changes therein detailed merely indicating the progress made up to the end of 1912.

Medical Inspection.

Section 13 of the Education Act of 1907, having imposed upon local authorities the responsibility of providing for the medical inspection of all children on admission to school, the need for coördination of the inspection and treatment of school children at once became manifest. This section gave power to make provision for preserving the health and physical welfare of the children. As regards inspection a beginning had already been made in 1889, when the late School Board appointed a part-time medical officer to advise them on medical matters generally and particularly as to the examination of candidates for permanent school appointments. When, in 1904, the County Council assumed control of the work previously carried out by the board, the school medical staff consisted of a medical officer and four assistants. There were also six oculists and six ringworm nurses. As illustrating the growth of this work in recent years, it may be mentioned that whilst in the year 1907 the number of children examined was 20,000 (of whom 6200 urgently needed treatment), in the year 1912 nearly 260,000 were examined, and treatment was actually administered to 28,000. In the early part of the latter year the work of inspection in London was performed by 64 quarter-time, 8 half-time, and 6 full-time doctors; and, later in that year, by 30 full-time and 4 quarter-time doctors, acting under the direction of 4 divisional medical officers—the doctors being assisted in their work by a staff of 90 nurses. The regulations of the Board of Education require the examination of all children on entering school life, and of children reaching school-leaving age. In addition to this the London County Council have arranged for the examination of children of 8 or 9 years old, and in urgent or special cases at other ages also. At the time of examination the children are weighed and measured, and careful note is taken of their clothing, cleanliness, nutrition, and condition of teeth. Reference to a table in the appendix shows that 36 per cent. of the children examined in the year under review were regarded as requiring medical treatment, whilst in the special class of children the percentage was 64. Of the children examined, 10 per cent. were found with enlarged tonsils, 6 per cent. with adenoids, and 5·4 per cent. with enlarged glands. Early phthisis was detected in 0·31 per cent. of the children, and other forms of tuberculosis in varying proportions. Diseases of the heart were present in 2·3 per cent., and diseases of the lungs (other than phthisis) in 3·2 per cent. of the total. 1·69 per cent. of the children were noted as the subjects of rickets, and 1·59 per cent. as being deformed—bow-legs, talipes, and chest malformations being common among younger children, and spinal curvatures among their elders, many of these defects being due to rickets.

Promotion of Cleanliness.

A scheme was devised in 1905 for dealing with the general condition of school children, the promotion of cleanliness, and the control of infectious disease amongst them. To carry out this work a permanent half-time assistant and 20 quarter-time temporary assistants were appointed in place of the six oculists. For dealing with ringworm and securing personal cleanliness a superintendent and 26 nurses were added to the staff.

Medical Treatment.

When the detailed inspection of school children was undertaken early in 1909 a further increase of the medical staff was found necessary, and at the end of that year 56 men and 12 women were employed by the Council. About this time the inadequacy of existing arrangements for medical treatment was brought into prominence. As the result of inspection the number of school children attending hospital became so great that many of the larger institutions were compelled to limit the number of their attendances on any one day. In these circumstances the Council found it necessary to devise a scheme for the more efficient coördination of inspection and treatment, and especially for increasing facilities for the latter. In the present report the story of the growth of this scheme is briefly related, but it deserves mention here that, beginning in 1910 by agreement with six hospitals, the Council had by the end of 1912 completed arrangements with 11 hospitals and 17 "treatment centres" for dealing with 54,208 children suffering from diseases of the eye, nose, and throat, or else from ringworm or from minor ailments. The proposal to include hospitals in the Council's scheme met with much criticism. It appears, however, to have been the intention of those responsible for the Act of 1907 that all voluntary agencies for treatment of the sick should be propitiated, and this view is held by the Board of Education, who advise that before the direct treatment of ailments is undertaken by the education authority out of the rates advantage should be taken of existing institutions. As the result of full inquiry and consultation with the Board the Council were convinced that the London hospitals fill, and must continue to fill, an important place in any arrangement for the treatment of school children.

[6] Die Homosexualität des Mannes und des Weibes. Von Dr. med. Magnus Hirschfeld. Berlin: Louis Marcus Verlagsbuchhandlung. 1914. Pp. 1068. 12 marks.

Medical Treatment Centres.

The Council have supplemented their hospital arrangements by entering into agreements with committees of local practitioners for the treatment of certain ailments at "medical treatment centres." The first of these was established tentatively at Hampstead in 1910, but was soon discontinued; a second was opened at Norwood and a third at Wandsworth. Subsequently the Council proposed to extend the system generally, but the Board of Education objected unless important modifications were agreed to. After several conferences the Board ultimately sanctioned the Council's scheme. Consequently the hope is now entertained that in the near future every district remote from hospitals will in this way be provided for. Recently effected agreements with nursing associations have been the means of providing for the treatment of discharging ears and other ailments requiring the services of a skilled nurse.

"Following Up" by Children's Care Committees.

In connexion with the feeding of necessitous children care committees were established in 1907, their functions having since been extended to include provision for "following up" by medical treatment, home visiting, and after-care. The following-up arrangements have been further improved by the assignment to each child of a special card which is kept at the school, and upon which the doctors enter particulars of defects or ailments and of the treatment prescribed. By this method each case is kept under observation until discharge. A large number of examinations of older children ("leavers") are carried out, and a leaflet has been distributed to their parents showing the disability, from a medical point of view, attaching to certain industrial employments. The "healthy hints" pamphlet has been revised, and sections have been added dealing with the care of teeth, discharging ears, and ringworm.

Cleansing Verminous Children.

At the end of the year under notice 22 nurses were engaged in securing the cleanliness of children and the treatment of ringworm. Out of 630,000 children examined, the heads or bodies were verminous in 24,000 instances; 10,000 children were cleansed by the Council's servants, and a similar number by the parents. From the foregoing it will be seen that effort is being steadily directed towards coördination of inspection and treatment, and that considerable progress has been made in developing a uniform scheme.

Fleas and Infectious Disease.

In the report for 1911 the question is discussed of the seasonal prevalence of three particular kinds of vermin—fleas, lice, and bugs. The high autumnal level of the flea and bug curves suggests comparison with the curves of diseases that have an autumnal prevalence. The mode of spread of infectious diseases is by no means completely understood, and the possibility of biting insects acting as carriers of infection cannot be ignored. In the present report this subject is further discussed, particulars having been obtained of the seasonal prevalence of fleas among the frequenters of common lodging-houses and also amongst elementary school children. These data have been represented in a diagram in which the proportions of flea-marked children in the last quarter of 1912 have been plotted out.

Control of Infectious Disease in Schools.

The rules for the guidance of teachers in dealing with infectious diseases in schools or in the children's homes have recently been revised.

Diphtheria and scarlet fever.—Both patients and contacts are now required to remain away from school until the expiration of a fortnight from the date of the disinfection of the premises after either of these diseases. The close association of scarlet fever and diphtheria in certain schools has again been observed in the year under notice. It is important to note that the persistence of the two diseases in the affected schools was maintained in spite of the careful exercise of preventive measures, including, in the case of diphtheria, the carrying out of bacteriological examinations and the exclusion of possible carriers of pathogenic bacilli. The facts already known clearly indicate that the question of the association of these diseases needs further study. The discovery of carrier cases of disease has caused much perplexity in sanitary administration. It is not possible, for instance, to affirm the presence of actual diphtheria in cases where definite clinical symptoms are absent, nor can it be maintained that persons harbouring diphtheria bacilli without outward manifestations of the disease are in every case dangerously infectious. Consequently such cases are excluded from the scope of the London Public Health Act of 1891. A rigid policy of exclusion from school is consistently adopted in such cases, as far as children are concerned, but the problem of dealing effectually with cases outside the jurisdiction of the education authority still remains to be solved.

Measles.—The new rules require that children who had been in contact with cases of measles at home and had not previously suffered from the disease should be excluded from school until the expiration of at least a fortnight from the commencement of the last case in the house. Measles and German measles are now dealt with separately.

Whooping-cough and chicken-pox.—The exclusion period for "contacts" has been altered to three weeks instead of two weeks as formerly, and for unprotected children the period must be calculated from the onset of illness of the last case in the house instead of the first.

Sore-throat.—All cases of sore-throat of whatever description are now required to be excluded from school.

Ringworm.—The rule has now been withdrawn under which children suffering from ringworm elsewhere than on the scalp were formerly allowed to attend school.

Care of the Teeth.

In order that the utmost benefit might be derived from Dr. R. A. Kirby's generous offer to provide for one year dental treatment free of cost at St. George's Dispensary, a scheme was devised by the council in 1910 from which the existing organisation for general dental treatment has been developed; consequently St. George's Dispensary has become one of the most popular of the centres for these cases. The appointment of dental inspectors to obtain the necessary attendance of defective children has been of great benefit, inasmuch as the purely medical inspection does not cover the age group of children amongst whom cases for conservative treatment are chiefly to be found. In addition to their routine work much of the dental inspectors' time is devoted to advising and securing the coöperation of parents in regard to the state of the teeth of their children.

Government Grant in Aid.

The State has now recognised the claim of local authorities for grants towards the expenses of medical treatment of school children, and a sum of £60,000 has been placed on the Education Estimates for the purpose. The amount actually expended during the year under notice for the work carried out in London in respect of the medical and surgical treatment of children attending elementary schools, and of work ancillary to such treatment, was returned as £12,958.

THE REORGANISATION OF THE SCHOOL MEDICAL STAFF IN LONDON.

IN order to meet the view of the Board of Education that the efficiency of the school medical service may suffer unless more variety is introduced into the work of school medical officers, and to comply with a suggestion that in certain respects the arrangements for medical inspection were capable of improvement,[1] the London County Council has decided to divide the county into five districts instead of four, the staff of each division to be under the control of a divisional officer and to consist of a nucleus of permanent medical assistants, the remainder of the staff consisting partly of full-time temporary medical assistants appointed for three years only and partly of temporary part-time medical inspectors. The Board of Education suggested that the duties of the permanent officers might be extended to include further examination of visual defects, public health work, including investigations of infectious diseases in schools, medical inspection of children in secondary schools, scholarship candidates, &c., work in connexion with special schools, research and laboratory work, and some share in the working of the administrative arrangements. Furthermore, in order to earn the full 50 per cent. grant towards the cost of medical inspection and treatment, the Board requires that provision should be made for completing the scheme of re-inspection of children found defective, including the continuous observation of tuberculous children, for special examinations in connexion with visual and aural defects and cases requiring nursing treatment, and for more complete control of outbreaks of infectious disease.

The Education Committee proposed that, as from April 1st, 1914, there should be five divisional medical officers at a commencing salary of £500 a year, rising by annual increments of £25 to £600; 15 full-time permanent medical assistants (three in each district) at salaries commencing at £400 a year and rising by annual increments of £25 to £500 a year; 20 full-time temporary medical assistants at salaries of £400 a year; and 18 quarter-time school doctors at salaries of £132 a year. The last two classes were only to be appointed for a period of three years. The cost of the increases of staff would be £6083 in 1914–15 and £7271 a year ultimately. The Council on March 24th approved appointments and re-arrangements of the school medical staff in order to fill the positions indicated above, and resolved :—

(a) That Mr. J. G. Forbes, Mr. A. W. Sikes, and Mr. F. W. Higgs, medical assistants in the public health department, be designated "divisional medical officers."

(b) That Mr. F. C. Lewis (£450), a medical assistant in the public health department, be promoted to be a divisional medical officer at the commencing salary of £500 a year, rising by annual increments of £25 to £600 a year.

(c) That the salary (£400 a year since September, 1913) of Mr. T. J. T. McHattie, a medical assistant in the public health department, be increased to £425 a year.

(d) That Dr. A. R. Cowell, Dr. H. F. Marris, Dr. R. H. Norman, Dr. W. J. M. Slowan, and Dr. A. G. Wells be appointed medical assistants in the public health department, each at a commencing salary of £425 a year; Mr. L. R. Tosswill, Dr. Mabel Russell, and Dr. F. T. H. Wood to be medical assistants, each at a commencing salary of £400 a year, rising in both instances by £25 a year to £500 a year.

(e) That the services of Miss Ruth Balmer, Mr. E. J. Boome, Mr. Cresswell Burrows, Mr. A. M. Davies, Miss J. G. Duncan, Miss M. G. Edis, Miss M. C. Macdonald, Miss E. M. McVail, Mr. E. F. Palgrave, and Mr. O. H. Peters be temporarily retained for a period not exceeding three years as medical assistants in the public health department, each at a salary at the rate of £400 a year.

(f) That the services of Dr. C. F. Hadfield, Miss Rose Jordan, Dr F. S. Langmead, Mr. E. J. Morton, Mr. E. B. Smith, and Dr. Oliver K. Williamson be retained for a period not exceeding two years as quarter-time school doctors, each at a salary at the rate of £132 a year.

Permission has been given for the school organisation to be used in connexion with investigations which Mrs. Frances Wood desires to carry out in certain schools with the object of ascertaining whether there was any correlation between the home environment of a child and its mental ability and physical characteristics. The work is to be carried out in the statistical laboratory of the Lister Institute of Preventive Medicine under the direction of Mr. Major Greenwood, jun.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of Durham.—Dr. T. Eustace Hill's last annual report contains as usual a variety of interesting information. The shire of Durham, which includes a large mining population, continues to increase the number of its inhabitants, which is now estimated at about 952,000. In 1912 the number of births was 29,671 and the deaths 13,111, giving a "natural increase" of births over deaths of 16,560. It is true that the birth-rate shows a tendency to fall—for 1912 it was 31·2, as compared with 36·9 in 1891–5—and that, notwithstanding a steady simultaneous fall in the general death-rate, the proportionate "natural increase" is now somewhat less than formerly; but even on present figures the Durham rate, if it obtained throughout the country, would occasion serious problems of over-population. The county has an excess of males: 100 to every 95·5 females, as against 106·8 females in the case of England and Wales; the preponderance is notable at all ages after 15, and no doubt signifies a large amount of female emigration as well as of male immigration. A relatively high infant mortality rate accompanies the high birth-rate, but this also has fallen conspicuously in recent years, and for 1912 was no higher than 106 per 1000 births, as compared with 95 per 1000 for England and Wales. The rural districts of Durham have a higher infant death-rate than the urban; but it has to be remembered that many of the so-called rural districts contain large aggregations of population living under urban conditions. Last year the adoption of the Notification of Births Act was made obligatory all over the county at the instance of the county council, but in the period reviewed in this report this Act was operative in six districts only. For these districts the county council appointed and maintained health visitors and nurses, and the complete scheme now contemplated will entail the appointment of 40 such visitors, on the basis of 1 to every 25,000 persons. It is proposed that the health visitors should also undertake the duties of visiting persons suffering from tuberculosis and of following up school children ascertained to be suffering from physical defects requiring attention or treatment. A notable decline has taken place in the mortality from, and prevalence of, enteric fever, in regard to which the county of Durham formerly had an unenviable pre-eminence. This must in large measure be attributed to progress in the matter of sewage and improved water-supplies, and the efforts which have been made to abolish the insalubrious middens which are so characteristic of many of the towns and villages in the county. Progress, though slow, is being made in replacing by properly constructed covered drains the objectionable open channels which are so frequently used in the colliery villages for the conveyance of slop-water and waste-water, while in Stockton and other places the local authorities have at length decided on an active policy of systematic conversion of midden privies to water closets. Much, however, has still to be done to mitigate the nuisances caused by the insanitary practice of depositing house refuse and midden contents on the footpaths and roadways to await the uncertain arrival of the scavengers' carts, to get the roads in new neighbourhoods properly made up, and generally to prevent the numerous causes of soil pollution which obtain in the mining villages and elsewhere. It is to the credit of the county council and its medical officer of health that in Durham a very active policy has been pursued for many years in regard to the improvement of housing conditions. Dr. Hill gives some specimens of useful forms for recording the results of inspection of working-class property, and shows that as a whole the various districts in the county have substantial housing improvements to their credit. The report gives a detailed account of a long-standing dispute between the county authorities and the district council of Benfieldside on the question whether the old type of miner's cottage can be made reasonably fit for human habitation by any method short of rebuilding the upper storey and raising the roof. The Local Government Board, as a result of a test case, endorsed the county view that the raising of the roofs so that the upper rooms have an average height of 8 feet would be desirable, but was unable to rule out alternative improvements, such as the provision of dormer windows and this time the inadequacy of existing arrangements for medical treatment was brought into prominence. As the result of inspection the number of school children attending hospital became so great that many of the larger institutions were compelled to limit the number of their attendances on any one day. In these circumstances the Council found it necessary to devise a scheme for the more efficient coördination of inspection and treatment, and especially for increasing facilities for the latter. In the present report the story of the growth of this scheme is briefly related, but it deserves mention here that, beginning in 1910 by agreement with six hospitals, the Council had by the end of 1912 completed arrangements with 11 hospitals and 17 "treatment centres" for dealing with 54,208 children suffering from diseases of the eye, nose, and throat, or else from ringworm or from minor ailments. The proposal to include hospitals in the Council's scheme met with much criticism. It appears, however, to have been the intention of those responsible for the Act of 1907 that all voluntary agencies for treatment of the sick should be propitiated, and this view is held by the Board of Education, who advise that before the direct treatment of ailments is undertaken by the education authority out of the rates advantage should be taken of existing institutions. As the result of full inquiry and consultation with the Board the Council were convinced that the London hospitals fill, and must continue to fill, an important place in any arrangement for the treatment of school children.

Medical Treatment Centres.

The Council have supplemented their hospital arrangements by entering into agreements with committees of local practitioners for the treatment of certain ailments at "medical treatment centres." The first of these was established tentatively at Hampstead in 1910, but was soon discontinued; a second was opened at Norwood and a third at Wandsworth. Subsequently the Council proposed to extend the system generally, but the Board of Education objected unless important modifications were agreed to. After several conferences the Board ultimately sanctioned the Council's scheme. Consequently the hope is now entertained that in the near future every district remote from hospitals will in this way be provided for. Recently effected agreements with nursing associations have been the means of providing for the treatment of discharging ears and other ailments requiring the services of a skilled nurse.

"Following Up" by Children's Care Committees.

In connexion with the feeding of necessitous children care committees were established in 1907, their functions having since been extended to include provision for "following up" by medical treatment, home visiting, and after-care. The following-up arrangements have been further improved by the assignment to each child of a special card which is kept at the school, and upon which the doctors enter particulars of defects or ailments and of the treatment prescribed. By this method each case is kept under observation until discharge. A large number of examinations of older children ("leavers") are carried out, and a leaflet has been distributed to their parents showing the disability, from a medical point of view, attaching to certain industrial employments. The "healthy hints" pamphlet has been revised, and sections have been added dealing with the care of teeth, discharging ears, and ringworm.

Cleansing Verminous Children.

At the end of the year under notice 22 nurses were engaged in securing the cleanliness of children and the treatment of ringworm. Out of 630,000 children examined, the heads or bodies were verminous in 24,000 instances; 10,000 children were cleansed by the Council's servants, and a similar number by the parents. From the foregoing it will be seen that effort is being steadily directed towards coördination of inspection and treatment, and that considerable progress has been made in developing a uniform scheme.

Fleas and Infectious Disease.

In the report for 1911 the question is discussed of the seasonal prevalence of three particular kinds of vermin—fleas, lice, and bugs. The high autumnal level of the flea and bug curves suggests comparison with the curves of diseases that have an autumnal prevalence. The mode of spread of infectious diseases is by no means completely understood, and the possibility of biting insects acting as carriers of infection cannot be ignored. In the present report this subject is further discussed, particulars having been obtained of the seasonal prevalence of fleas among the frequenters of common lodging-houses and also amongst elementary school children. These data have been represented in a diagram in which the proportions of flea-marked children in the last quarter of 1912 have been plotted out.

Control of Infectious Disease in Schools.

The rules for the guidance of teachers in dealing with infectious diseases in schools or in the children's homes have recently been revised.

Diphtheria and scarlet fever.—Both patients and contacts are now required to remain away from school until the expiration of a fortnight from the date of the disinfection of the premises after either of these diseases. The close association of scarlet fever and diphtheria in certain schools has again been observed in the year under notice. It is important to note that the persistence of the two diseases in the affected schools was maintained in spite of the careful exercise of preventive measures, including, in the case of diphtheria, the carrying out of bacteriological examinations and the exclusion of possible carriers of pathogenic bacilli. The facts already known clearly indicate that the question of the association of these diseases needs further study. The discovery of carrier cases of disease has caused much perplexity in sanitary administration. It is not possible, for instance, to affirm the presence of actual diphtheria in cases where definite clinical symptoms are absent, nor can it be maintained that persons harbouring diphtheria bacilli without outward manifestations of the disease are in every case dangerously infectious. Consequently such cases are excluded from the scope of the London Public Health Act of 1891. A rigid policy of exclusion from school is consistently adopted in such cases, as far as children are concerned, but the problem of dealing effectually with cases outside the jurisdiction of the education authority still remains to be solved.

Measles.—The new rules require that children who had been in contact with cases of measles at home and had not previously suffered from the disease should be excluded from school until the expiration of at least a fortnight from the commencement of the last case in the house. Measles and German measles are now dealt with separately.

Whooping-cough and chicken-pox.—The exclusion period for "contacts" has been altered to three weeks instead of two weeks as formerly, and for unprotected children the period must be calculated from the onset of illness of the last case in the house instead of the first.

Sore-throat.—All cases of sore-throat of whatever description are now required to be excluded from school.

Ringworm.—The rule has now been withdrawn under which children suffering from ringworm elsewhere than on the scalp were formerly allowed to attend school.

Care of the Teeth.

In order that the utmost benefit might be derived from Dr. R. A. Kirby's generous offer to provide for one year dental treatment free of cost at St. George's Dispensary, a scheme was devised by the council in 1910 from which the existing organisation for general dental treatment has been developed; consequently St. George's Dispensary has become one of the most popular of the centres for these cases. The appointment of dental inspectors to obtain the necessary attendance of defective children has been of great benefit, inasmuch as the purely medical inspection does not cover the age group of children amongst whom cases for conservative treatment are chiefly to be found. In addition to their routine work much of the dental inspectors' time is devoted to advising and securing the coöperation of parents in regard to the state of the teeth of their children.

Government Grant in Aid.

The State has now recognised the claim of local authorities for grants towards the expenses of medical treatment of school children, and a sum of £60,000 has been placed on the Education Estimates for the purpose. The amount actually expended during the year under notice for the work carried out in London in respect of the medical and surgical treatment of children attending elementary schools, and of work ancillary to such treatment, was returned as £12,958.

THE REORGANISATION OF THE SCHOOL MEDICAL STAFF IN LONDON.

IN order to meet the view of the Board of Education that the efficiency of the school medical service may suffer unless more variety is introduced into the work of school medical officers, and to comply with a suggestion that in certain respects the arrangements for medical inspection were capable of improvement,[1] the London County Council has decided to divide the county into five districts instead of four, the staff of each division to be under the control of a divisional officer and to consist of a nucleus of permanent medical assistants, the remainder of the staff consisting partly of full-time temporary medical assistants appointed for three years only and partly of temporary part-time medical inspectors. The Board of Education suggested that the duties of the permanent officers might be extended to include further examination of visual defects, public health work, including investigations of infectious diseases in schools, medical inspection of children in secondary schools, scholarship candidates, &c., work in connexion with special schools, research and laboratory work, and some share in the working of the administrative arrangements. Furthermore, in order to earn the full 50 per cent. grant towards the cost of medical inspection and treatment, the Board requires that provision should be made for completing the scheme of re-inspection of children found defective, including the continuous observation of tuberculous children, for special examinations in connexion with visual and aural defects and cases requiring nursing treatment, and for more complete control of outbreaks of infectious disease.

The Education Committee proposed that, as from April 1st, 1914, there should be five divisional medical officers at a commencing salary of £500 a year, rising by annual increments of £25 to £600; 15 full-time permanent medical assistants (three in each district) at salaries commencing at £400 a year and rising by annual increments of £25 to £500 a year; 20 full-time temporary medical assistants at salaries of £400 a year; and 18 quarter-time school doctors at salaries of £132 a year. The last two classes were only to be appointed for a period of three years. The cost of the increases of staff would be £6083 in 1914–15 and £7271 a year ultimately. The Council on March 24th approved appointments and re-arrangements of the school medical staff in order to fill the positions indicated above, and resolved:—

> (a) That Mr. J. G. Forbes, Mr. A. W. Sikes, and Mr. F. W. Higgs, medical assistants in the public health department, be designated "divisional medical officers."
>
> (b) That Mr. F. C. Lewis (£450), a medical assistant in the public health department, be promoted to be a divisional medical officer at the commencing salary of £500 a year, rising by annual increments of £25 to £600 a year.
>
> (c) That the salary (£400 a year since September, 1913) of Mr. T. J. T. McHattie, a medical assistant in the public health department, be increased to £425 a year.
>
> (d) That Dr. A. R. Cowell, Dr. H. F. Marris, Dr. R. H. Norman, Dr. W. J. M. Slowan, and Dr. A. G. Wells be appointed medical assistants in the public health department, each at a commencing salary of £425 a year; Mr. L. R. Tosswill, Dr. Mabel Russell, and Dr. F. T. H. Wood to be medical assistants, each at a commencing salary of £400 a year, rising in both instances by £25 a year to £500 a year.
>
> (e) That the services of Miss Ruth Balmer, Mr. E. J. Boome, Mr. Cresswell Burrows, Mr. A. M. Davies, Miss J. G. Duncan, Miss M. G. Edis, Miss M. C. Macdonald, Miss E. M. McVail, Mr. E. F. Palgrave, and Mr. O. H. Peters be temporarily retained for a period not exceeding three years as medical assistants in the public health department, each at a salary at the rate of £400 a year.
>
> (f) That the services of Dr. C. F. Hadfield, Miss Rose Jordan, Dr. F. S. Langmead, Mr. E. J. Morton, Mr. E. B. Smith, and Dr. Oliver K. Williamson be retained for a period not exceeding two years as quarter-time school doctors, each at a salary at the rate of £132 a year.

Permission has been given for the school organisation to be used in connexion with investigations which Mrs. Frances Wood desires to carry out in certain schools with the object of ascertaining whether there was any correlation between the home environment of a child and its mental ability and physical characteristics. The work is to be carried out in the statistical laboratory of the Lister Institute of Preventive Medicine under the direction of Mr. Major Greenwood, jun.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of Durham.—Dr. T. Eustace Hill's last annual report contains as usual a variety of interesting information. The shire of Durham, which includes a large mining population, continues to increase the number of its inhabitants, which is now estimated at about 952,000. In 1912 the number of births was 29,671 and the deaths 13,111, giving a "natural increase" of births over deaths of 16,560. It is true that the birth-rate shows a tendency to fall—for 1912 it was 31·2, as compared with 36·9 in 1891–5—and that, notwithstanding a steady simultaneous fall in the general death-rate, the proportionate "natural increase" is now somewhat less than formerly; but even on present figures the Durham rate, if it obtained throughout the country, would occasion serious problems of over-population. The county has an excess of males: 100 to every 95·5 females, as against 106·8 females in the case of England and Wales; the preponderance is notable at all ages after 15, and no doubt signifies a large amount of female emigration as well as of male immigration. A relatively high infant mortality rate accompanies the high birth-rate, but this also has fallen conspicuously in recent years, and for 1912 was no higher than 106 per 1000 births, as compared with 95 per 1000 for England and Wales. The rural districts of Durham have a higher infant death-rate than the urban; but it has to be remembered that many of the so-called rural districts contain large aggregations of population living under urban conditions. Last year the adoption of the Notification of Births Act was made obligatory all over the county at the instance of the county council, but in the period reviewed in this report this Act was operative in six districts only. For these districts the county council appointed and maintained health visitors and nurses, and the complete scheme now contemplated will entail the appointment of 40 such visitors, on the basis of 1 to every 25,000 persons. It is proposed that the health visitors should also undertake the duties of visiting persons suffering from tuberculosis and of following up school children ascertained to be suffering from physical defects requiring attention or treatment. A notable decline has taken place in the mortality from, and prevalence of, enteric fever, in regard to which the county of Durham formerly had an unenviable pre-eminence. This must in large measure be attributed to progress in the matter of sewage and improved water-supplies, and the efforts which have been made to abolish the insalubrious middens which are so characteristic of many of the towns and villages in the county. Progress, though slow, is being made in replacing by properly constructed covered drains the objectionable open channels which are so frequently used in the colliery villages for the conveyance of slop-water and waste-water, while in Stockton and other places the local authorities have at length decided on an active policy of systematic conversion of midden privies to water closets. Much, however, has still to be done to mitigate the nuisances caused by the insanitary practice of depositing house refuse and midden contents on the footpaths and roadways to await the uncertain arrival of the scavengers' carts, to get the roads in new neighbourhoods properly made up, and generally to prevent the numerous causes of soil pollution which obtain in the mining villages and elsewhere. It is to the credit of the county council and its medical officer of health that in Durham a very active policy has been pursued for many years in regard to the improvement of housing conditions. Dr. Hill gives some specimens of useful forms for recording the results of inspection of working-class property, and shows that as a whole the various districts in the county have substantial housing improvements to their credit. The report gives a detailed account of a long-standing dispute between the county authorities and the district council of Benfieldside on the question whether the old type of miner's cottage can be made reasonably fit for human habitation by any method short of rebuilding the upper storey and raising the roof. The Local Government Board, as a result of a test case, endorsed the county view that the raising of the roofs so that the upper rooms have an average height of 8 feet would be desirable, but was unable to rule out alternative improvements, such as the provision of dormer windows and fireplaces, which did not necessitate so large a reconstruction. Dr. Hill considers this decision disappointing, and liable to have a retrograde effect. The county appointed a tuberculosis officer in November, 1912; dispensaries have been organised for tuberculosis, and various arrangements made to obtain beds in existing sanatoriums. The county arrangements with the Durham University College of Medicine for the examination of specimens for evidence of diphtheria, enteric fever, and tuberculosis have been augmented. The privilege of sending such specimens and receiving reports free of charge extends to all medical practitioners practising in the county.

---

[1] THE LANCET, August 2nd, 1913, p. 323.

County of Radnor.—Dr. L. W. Pole refers to the steps taken by the Welsh National Memorial to provide treatment for cases of tuberculosis in Wales and to the want of sufficient interrelation between the work of the Memorial and that required of public health authorities. Up to the present, Dr. Pole states, the amount of coöperation between county council officials and those of the Memorial Association has been insignificant. The time has come, he considers, for the county officer to be fully informed as to all work done in the county by the Memorial physicians. On the other hand, sanitary authorities ought to coöperate with the Memorial authorities and bring to light conditions which promote the spread of tuberculosis, especially in the matter of inspection of premises and action to deal with dampness of dwellings, want of ventilation, insufficient cubic space, and overcrowding. The housing difficulty in many parts of this county appears to be acute, and houses quite unfit for habitation cannot be closed on account of the difficulty of finding any accommodation for the families displaced. Dr. Pole represents to the county council the importance of their county medical officer of health having more time and greater facilities for investigation of housing conditions.

Urban and Port Sanitary District of Barry.—If confidence may be placed in the examinations of cows made by the dairy cows inspector in Barry this town is exceptionally free from tuberculous milk due to mammary tuberculosis. During the whole of 1913 only one case of tuberculosis of the udder was found in the course of 168 visits to cowsheds in which 1700 cows were examined. Catarrhal mammitis and various forms of udder disease, on the other hand, were frequently found, and in the case of 61 cows total or partial prohibition of the use of the milk was ordered on this account. In the slaughter-houses cows were found affected by tuberculosis to the extent of 12 per cent., steers and heifers 1·5 per cent., and pigs 1 per cent. From 200 lb. to 1000 lb. weight of tuberculous meat was condemned and destroyed each month during 1913. In view of the possibility of plague being imported by rats on grain ships and other ships arriving from suspected ports, special measures have been continued to deal with these rodents, and it is considered that the number of rats on dock premises is being diminished year by year. The medical officer of health of this district and port, Mr. G. Neale, gives special attention to the inspection of shipping, and the practice is followed of inspecting vessels immediately on their arrival, so that notices and orders as to cleansing and sanitary repairs can be executed as far as possible before the ship departs for another port. The difficulty of maintaining cleanly conditions in the living quarters of ships is specially great where, as is usually the case at Barry, the ships are employed in the coal trade. These ships frequently bring large cargoes of pit wood, which is often piled on the decks so as to obstruct the approach, ventilation, and lighting of the forecastle, in which the firemen and sailors are usually housed. When regard is had to the deficient air space, light, and ventilation of the forecastle sleeping quarters in ordinary circumstances, it seems highly undesirable that these deficiencies should be increased by the apparently unnecessary practice to which Mr. Neale here directs attention.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 7853 births and 5212 deaths were registered during the week ended Saturday, April 11th. The annual rate of mortality in these towns, which had been 15·2, 16·5, and 16·2 per 1000 in the three preceding weeks, further declined to 15·0 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 16·4, against 16·1 per 1000 in London during the same period. Among the several towns the death-rate in the week under review ranged from 6·3 in Ilford, 8·9 in Croydon, 9·1 in Devonport, 9·2 in Coventry, and 9·3 in East Ham and in Reading, to 20·6 in Middlesbrough, 21·0 in Gateshead, 21·3 in Barnsley, 22·7 in Rochdale, and 24·2 in Burnley.

The 5212 deaths from all causes were 418 fewer than the number in the previous week, and included 433 which were referred to the principal epidemic diseases, against 488 and 484 in the two preceding weeks. Of these 433 deaths, 150 resulted from whooping-cough, 134 from measles, 54 from infantile diarrhœal diseases, 44 from diphtheria, 39 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·2, against 1·4 per 1000 in each of the two preceding weeks. The deaths attributed to whooping-cough, which had steadily increased from 110 to 172 in the seven preceding weeks, fell to 150, and caused the highest annual death-rates of 1·6 in Middlesbrough, 1·7 in Exeter, 1·8 in Darlington, 2·2 in Rochdale, and 2·6 in Swansea. The deaths referred to measles, which had been 107, 140, and 137 in the three preceding weeks, further decreased to 134; the highest death-rates from this disease were 1·3 in Bradford, 1·6 in Leicester, 1·8 in Stockton-on-Tees, 1·9 in Barnsley, 2·1 in Middlesbrough and in Swansea, and 2·9 in Nottingham. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 73, 65, and 77 in the three preceding weeks, declined to 54, of which 13 were registered in London, 5 in Birmingham, 4 in Swansea, and 3 in West Ham. The deaths attributed to diphtheria, which had been 51, 73, and 51 in the three preceding weeks, further fell to 44, and included 9 in London, 3 in Birmingham, and 2 each in Wimbledon, Devonport, Liverpool, Bolton, Newport, (Mon.), and Cardiff. The deaths referred to scarlet fever, which had been 37, 33, and 35 in the three preceding weeks, further rose to 39; 5 deaths occurred in Birmingham, 4 in Manchester, 4 in Sheffield, and 3 in Salford. The fatal cases of enteric fever, which had been 21, 15, and 12 in the three preceding weeks, were again 12 in the week under notice, but showed no excess in any of the towns.

The number of scarlet fever patients under treatment in the London Fever and the Metropolitan Asylums Hospitals, which had been 3173, 3143, and 3182 at the end of the three preceding weeks, had declined to 3068 on Saturday, April 11th: 306 new cases were admitted during the week, against 319, 347, and 399 in the three preceding weeks. These hospitals also contained on Saturday, April 11th, 1245 cases of diphtheria, 360 of whooping-cough, 123 of measles, and 63 of enteric fever, but not one of small-pox. The 1170 deaths from all causes in London were 174 fewer than the number registered in the previous week, and were equal to an annual death-rate of 13·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 250, 291, and 280 in the three preceding weeks, further declined to 219 in the week under notice, and were 128 below the number recorded in the corresponding week of last year.

Of the 5212 deaths from all causes in the 97 towns, 173 resulted from various forms of violence, and 371 were the subject of coroners' inquests, while 1406 occurred in public institutions. The causes of 32, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, and in 75 other smaller towns. Of the 32 uncertified causes, 8 were recorded in Birmingham, 4 in Liverpool, 3 in St. Helens, and 2 each in Bury, Preston, Huddersfield, South Shields, and Merthyr Tydfil.

In the 97 English and Welsh towns 8946 births and 5192 deaths were registered during the week ended Saturday, April 18th. The annual rate of mortality in these towns, which had been 16·5, 16·2, and 15·0 per 1000 in the three preceding weeks, further fell to 14·9 per 1000 in the week under notice. Among the several towns the death-rate ranged from 6·0 in Enfield, 6·4 in Hornsey, 6·9 in Wakefield, 7·3 in Edmonton, and 7·4 in Ilford, to 21·6 in Gloucester, 22·2 in Barnsley, 24·3 in Rochdale, 25·5 in Stockton-on-Tees, and 29·1 in Dudley.

The 5192 deaths from all causes were 20 fewer than the number in the previous week, and included 438 which were referred to the principal epidemic diseases, against numbers declining from 488 to 433 in the three preceding weeks. Of these 438 deaths, 153 resulted from measles, 117 from whooping-cough, 61 from infantile diarrhœal diseases, 50 from diphtheria, 40 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3, against 1·4 and 1·2 per 1000 in the two preceding weeks. The deaths attributed to measles, which had been 140, 137, and

134 in the three preceding weeks, rose to 153 last week, and caused the highest highest annual death-rates of 2·3 in Nottingham and in Sheffield, 2·6 in Swansea, 2·8 in Bootle, 3·0 in Dudley, and 3·5 in Stockton-on-Tees. The deaths referred to whooping-cough, which had been 162, 172, and 150 in the three preceding weeks, further fell to 117 last week; of this number 26 occurred in London, 10 in Manchester, 7 in Birmingham, 6 in Sheffield, 6 in Swansea, 5 in Liverpool, and 4 each in West Ham, Leicester, and Bradford. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 65, 77, and 54 in the three preceding weeks, rose to 61 last week, and included 15 in London, 5 in Liverpool, 5 in Manchester, 4 in Birmingham, and 3 in Sheffield. The deaths attributed to diphtheria, which had been 73, 51, and 44 in the three preceding weeks, rose to 50 last week, of which 11 were registered in London, 3 in Bolton, 3 in Sheffield, 2 in Birmingham, and 2 in Liverpool. The deaths referred to scarlet fever, which had been 33, 35, and 39 in the three preceding weeks, were 40 last week; 7 deaths were recorded in London, 5 in Liverpool, 4 in Birmingham, 4 in Manchester, and 3 in Leeds. The fatal cases of enteric fever, which had been 12 in each of the two preceding weeks, rose to 17 last week, and included 3 in London and 2 each in Liverpool, Salford, and Sheffield.

The number of scarlet fever patients under treatment in the London Fever and the Metropolitan Asylums Hospitals, which had been 3143, 3182, and 3058 at the end of the three preceding weeks, had further declined to 2992 on Saturday last; 289 new cases were admitted during the week, against 347, 399, and 306 in the three preceding weeks. These hospitals also contained on Saturday last 1186 cases of diphtheria, 355 of whooping-cough, 115 of measles, and 68 of enteric fever, but not one of small-pox. The 1265 deaths from all causes in London were 85 in excess of the number in the previous week, and corresponded to an annual death-rate of 14·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 291, 280, and 219 in the three preceding weeks, rose to 263 in the week under notice, but were 22 below the number registered in the corresponding week of last year.

Of the 5192 deaths from all causes in the 97 towns, 220 resulted from various forms of violence, and 439 were the subject of coroners' inquests, while 1478 occurred in public institutions. The causes of 44, or 0·8 per cent., of the total deaths were not certified either by a registered practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 52 other smaller towns. Of the 44 uncertified causes of death, 7 were recorded in Birmingham, 7 in Liverpool, 4 in Stoke-on-Trent, and 2 each in Dudley, St. Helens, Southport, Preston, and Rotherham.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1140 births and 727 deaths were registered during the week ended Saturday, April 11th. The annual rate of mortality in these towns, which had been 16·6, 16·5, and 18·6 per 1000 in the three preceding weeks, declined to 16·5 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these Scotch towns averaged 18·2, against 16·4 per 1000 in the 97 large English towns. Among the several towns the death-rate in the week under review ranged from 11·0 in Falkirk, 11·8 in Leith, and 14·5 in Coatbridge, to 18·4 in Perth, 18·9 in Hamilton, and 24·1 in Kirkcaldy.

The 727 deaths from all causes were 92 fewer than the number in the previous week, and included 65 which were referred to the principal epidemic diseases, against numbers rising from 66 to 81 in the three preceding weeks. Of these 65 deaths, 31 resulted from measles, 12 from whooping-cough, 7 from diphtheria, 6 from scarlet fever, 5 from infantile diarrhœal diseases, and 4 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·5, against 1·2 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 38, 34, and 37 in the three preceding weeks, fell to 31. Of this number 22 were registered in Glasgow, 6 in Edinburgh, and 2 in Hamilton. The deaths referred to whooping-cough, which had increased from 8 to 15 in the four preceding weeks, fell to 12, and included 4 in Glasgow, 2 in Aberdeen, 2 in Coatbridge. and 2 in Kirkcaldy. The fatal cases of diphtheria, which had been 6, 9, and 9 in the three preceding weeks, fell to 7, and comprised 3 in Glasgow, 3 in Aberdeen, and 1 in Motherwell. The 6 deaths attributed to scarlet fever, of which 3 occurred in Glasgow, were 2 below the weekly average in the preceding quarter. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 14 in each of the two preceding weeks, fell to 5, of which 2 were registered in Dundee. Of the 4 fatal cases of enteric fever, 3 were recorded in Glasgow and 1 in Coatbridge.

The deaths referred to diseases of the respiratory system, which had been 117, 111, and 166 in the three preceding weeks, declined to 137 in the week under review; and 28 deaths resulted from various forms of violence, against numbers rising from 22 to 33 in the three preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 500 births and 470 deaths were registered during the week ended Saturday, April 11th. The annual rate of mortality in these towns, which had been 20·3, 22·8, and 21·7 per 1000 in the three preceding weeks, further fell to 20·3 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 21·5 per 1000; in the 97 large English towns the corresponding rate did not exceed 16·4, while in the 16 Scotch towns it was equal to 18·2 per 1000. The annual death-rate in the week under review was equal to 24·1 in Dublin (against 13·5 in London and 16·6 in Glasgow), 18·6 in Belfast, 19·7 in Cork, 22·8 in Londonderry, 16·2 in Limerick, and 11·4 in Waterford, while in the 21 smaller towns the mean death-rate was 18·1 per 1000.

The 470 deaths from all causes were 32 fewer than the number in the previous week, and included 63 which were referred to the principal epidemic diseases, against 67 and 48 in the two preceding weeks. Of these 63 deaths, 37 resulted from measles, 9 from whooping-cough, 8 from infantile diarrhœal diseases, 6 from scarlet fever, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·7, against corresponding rates of 1·2 and 1·5 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 16, 34, and 26 in the three preceding weeks, rose to 37, of which 34 occurred in Dublin, 2 in Belfast, and 1 in Limerick. The deaths referred to whooping-cough, which had been 11, 12, and 10 in the three preceding weeks, were 9, and comprised 6 in Belfast, 2 in Dublin, and 1 in Cork. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had declined from 14 to 6 in the four preceding weeks, rose to 8, and included 4 in Belfast and 2 in Dublin. The 6 deaths attributed to scarlet fever, of which 3 occurred in Dublin and 3 in Belfast, were equal to the weekly average in the preceding quarter. Of the 2 deaths referred to diphtheria, 1 occurred in Dublin and 1 in Belfast; the fatal case of enteric fever was recorded in Dublin.

The deaths referred to diseases of the respiratory system, which had increased from 97 to 118 in the five preceding weeks, fell to 102 in the week under notice. Of the 470 deaths from all causes, 128, or 27 per cent., occurred in public institutions and 7 resulted from various forms of violence. The causes of 16, or 3·4 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes did not exceed 0·6 per cent.

In the 27 town districts of Ireland 623 births and 519 deaths were registered during the week ended Saturday, April 18th. The annual rate of mortality in these towns, which had been 22·8, 21·7, and 20·3 per 1000 in the three preceding weeks, rose to 22·5 per 1000 in the week under notice, against corresponding rates of 14·9 and 16·0 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 26·1 in Dublin (against 14·5 in London and 16·5 in Glasgow), 21·2 in Belfast, 27·9 in Cork, 17·8 in Londonderry, 27·1 in Limerick, and 32·3 in Waterford; while in the 21 smaller towns the mean death-rate did not exceed 14·9 per 1000.

The 519 deaths from all causes were 49 in excess of the number in the previous week, and included 75 which were referred to the principal epidemic diseases, against 48 and 63 in the two preceding weeks. Of these 75 deaths, 42 resulted from measles, 14 from whooping-cough, 10 from infantile diarrhœal diseases, 5 from scarlet fever, 3 from enteric fever, and 1 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3·2 per 1000, against a corresponding rate of 1·3 per 1000 in the English towns. The deaths attributed to measles, which had been 34, 26, and 37 in the three preceding weeks, further rose to 42 last week, of which 39 occurred in Dublin, 2 in Belfast, and 1 in Lurgan. The deaths referred to whooping-cough, which had been 12, 10, and 9 in the three preceding weeks, rose to 14, and comprised 9 in Belfast, 4 in Dublin, and 1 in Cork. The fatal cases of diarrhœa and enteritis (among infants under two years), which had been 8, 6, and 8 in the three preceding weeks, rose to 10 last week, and included 7 in Dublin, 2 in Belfast, and 1 in Waterford. The 5 deaths attributed to scarlet fever, all of which occurred in Belfast, were equal to the average in the three preceding weeks. The fatal cases of enteric fever were recorded in Dublin, Cork, and Dundalk respectively, and that of diphtheria in Belfast.

The deaths referred to diseases of the respiratory system, which had been 113, 118, and 102 in the three preceding weeks, rose to 115 in the week under notice. Of the 519 deaths from all causes, 154, or 30 per cent., occurred in public institutions, and 8 resulted from various forms of violence. The causes of 17, or 3·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes last week did not exceed 0·8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Acting Surgeons have been confirmed in the rank of Surgeon in His Majesty's Fleet:—Percy Boyd Wallis (dated April 11th, 1913), and Arthur Richard Sharrod, John Stephen Elliot, Albert Joseph Tonkinson, Thomas John Kilbride, John Reid Haldane, Gerald Sylvester Harvey, John Phillips Blockley, William Hoare Murray, George Herbert Hayes, Henry Charles Aylmer Tandy Cannon, and Hugh James Hopps (dated Oct. 3rd, 1913).

The following appointments have been notified:—Staff-Surgeons: N. J. Roche and T. W. Jeffrey to the *Victory*, additional, for trials of the *Isis* and *Victor* respectively. Surgeon: C. F. O. Sankey to the *Dwarf*, on recommissioning. Acting Surgeons: A. E. Panter to the *Victory*, for course of instruction at Royal Medical School, R.N. College, Greenwich, and at Haslar Hospital; and F. C. Hunot, H. B. Parker, R. F. Quinton, M. J. Aitken, J. L. Priston, J. A. Maxwell, W. G. Thwaytes, M. S. Moore, W. F. Beattie, F. E. Fitzmaurice, C. E. Greeson, T. J. O'Riordan, J. C. Kelly, H. W. Fitzroy-Williams, T. Hill, J. M. Horan, and G. M. Graham to the *Victory*, for course of instruction.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenant-Colonels are placed on retired pay: Francis H. M. Burton (dated April 20th, 1914); and Michael L. Hearn (dated April 21st, 1914).

Major Edward M. Morphew to be Lieutenant-Colonel, vice F. H. M. Burton, retired (dated April 20th, 1914). Major Nicholas Tyacke to be Lieutenant-Colonel, vice M. L. Hearn, retired (dated April 21st, 1914).

Colonel C. Birt has been appointed Assistant Director of Medical Services to the Bombay Brigade. Brevet Colonel S. Hickson has been appointed Inspector of Medical Services at the War Office.

Lieutenant-Colonel R. H. Hall has been selected to hold charge of Queen Alexandra's Military Hospital at Cosham. Lieutenant-Colonel G. G. Adams has been appointed to hold charge of the Military Hospital at Secunderabad Cantonment. Lieutenant-Colonel T. Daly has been appointed to command No. 19 Company of the Royal Army Medical Corps at Chester and Senior Medical Officer North-Western Coast Defences. Lieutenant-Colonel S. Guise Moores has been appointed to hold charge of the Military Hospital at Warley. Lieutenant-Colonel H. M. Adamson has been appointed to hold charge of the Military Hospital at Belgaum Cantonment. Lieutenant-Colonel A. L. F. Bate has been appointed Senior Recruiting Medical Officer at Woolwich. Lieutenant-Colonel T. G. Lavie has joined at Malta.

Major M. H. G. Fell has been selected to succeed Lieutenant-Colonel S. Guise Moores as Deputy Assistant Director of Medical Services to the Aldershot Command. Major J. G. Gill has been appointed to the Southern Command. Major W. R. Blackwell has taken up duty at the War Office as Deputy Director-General, Medical Division. Major F. E. Gunter has been appointed to the Military Hospital at Tidworth. Major E. W. Bliss, Major J. Matthews, Major G. J. A. Orms, and Major E. F. Q. L'Estrange have arrived home from India. Major L. Cotterill has joined at Nowshera Cantonment. Major A. G. Thompson has been appointed to the Southern Command for duty. Major E. Brodribb has been transferred from Malta to Scutari. Major L. Addams-Williams has been appointed to Karachi Cantonment. Major A. H. Safford has been trans- ferred from Dublin to the Eastern Command. Major H. G. Pinches has been transferred from the Irish Command to the Chatham District. Major H. B. Fawcus has taken up duty as Instructor in Army Sanitation at the Depôt, Aldershot. Major G. H. Goddard has been placed in charge of the Military Hospital at Brighton. Major D. J. Collins has been appointed to hold charge of the Military Hospital at Kirkee Cantonment. Major C. E. Pollock has taken up duty in the Sierra Leone Protectorate. Major F. S. Penny has arrived home from Hong-Kong. Major D. E. Curme has been appointed to hold charge of the Military Hospital at Pontefract. Major R. W. Clements has arrived home for duty from Wellington. Major W. L. Baker has been appointed to the Recruiting Staff of the London District. Major H. C. R. Hime has been appointed Specialist in Ophthalmology to the Ninth (Secunderabad) Division of the Southern Army.

Captain S. Field has been appointed for duty in the Cork District. Captain M. J. Cromie has embarked for the Sierra Leone Protectorate. Captain A. H. T. Davis has been appointed Specialist in Radiography and Electrical Science to the Fourth (Poona) Division. Captain M. O. Wilson has been appointed to the Eastern Command. Captain T. B. Nicholls has been appointed to hold charge of the Military Hospital at Cyprus. Captain S. E. Lewis has taken over charge of the Military Families Hospital at Devonport. Captain E. G. R. Lithgow has been appointed Medical Officer to the Central Flying School at Upavon. Captain G. J. Keane has been appointed for special duty in Uganda under the Colonial Office. Captain A. H. Hayes has taken up duty as Staff Surgeon and in civil medical charge at Ambala Cantonment. Captain R. G. H. Tate has arrived home from India. Captain R. B. Hole has been appointed Adjutant at the Royal Army Medical Corps School of Instruction, Glasgow. Captain R. G. S. Gregg has taken up duty at Aden. Captain W. F. M. Loughnan has been appointed to the Eastern Command. Captain J. T. McEntire has been appointed to the Cork District for duty. Captain L. G. Gibson has been appointed to hold charge of the Military and Cantonment General Hospital at Amritsar. Captain C. E. L. Harding has joined at Aden. Captain H. O. M. Beadnell has been placed under orders for duty in Jamaica. Captain L. A. A. Andrews has been appointed Specialist in Dermatology and Venereal Diseases at the Military Hospital, York. Captain K. Comyn has been appointed to hold charge of the Pathological Laboratory at Gibraltar. Captain J. E. Hoar has joined at Sheerness. Captain A. M. Fraser has been appointed Specialist Sanitary Officer to the Garrison at Singapore. Captain J. R. Foster has been appointed to the Irish Command. Captain E. J. Elliott has been appointed to hold charge of the Military Hospital at Ashton. Captain S. M. W. Meadows has been appointed Specialist in Midwifery and Gynæcology at Tidworth. Captain H. C. Winkworth has embarked for India. Captain D. de C. O'Grady has been appointed to the Military Hospital at Chatham.

Lieutenant T. A. Watson has been appointed Specialist in Advanced Operative Surgery to the Eighth (Lucknow) Division. Lieutenant L. Buckley has been transferred from the Military Hospital at Rawal Pindi Cantonment to Ferozepore. Lieutenant W. W. O. Ball has been appointed for duty at Bordon Camp. Lieutenant H. Beddingfield has been transferred from Woolwich to Hounslow Barracks. Lieutenant H. S. Blackmore has been appointed to hold charge of the Bacteriological Research Laboratory at Brigade Headquarters, Bangalore Cantonment. Lieutenant S. P. Sykes has been transferred from Rawal Pindi to the Military Hospital at Jutogh. Lieutenant W. W. Pratt has embarked for India. Lieutenant T. E. Osmond has been appointed Specialist in Dermatology and Venereal Diseases to the Eighth (Lucknow) Division. Lieutenant H. J. G. Wells has been transferred from Nowshera to the Military Hospital at Rawal Pindi Cantonment.

INDIAN MEDICAL SERVICE.

The promotion of Major James Good to his present rank is antedated from June 28th, 1912, to Dec. 28th, 1911.

The King has approved the retirement of Colonel Robert Neil Campbell, C.B., C.I.E. (dated April 2nd, 1914).

Colonel C. C. Manifold has been granted six months' combined leave of absence home from India. Lieu- tenant-Colonel C. Milne has been transferred from Basti and appointed Civil Surgeon at Cawnpore. Lieutenant- Colonel P. Carr-White has been transferred from Kotah and appointed Residency Surgeon in Nepal State by the Foreign Department.

Major J. M. Wolley has been appointed to officiate as Superintendent of the Central Prison at Dacca. Major S. H. Lee-Abbott, Civil Surgeon at Ferozepore, has been granted two years' combined leave of absence home from India. Major J. W. D. Megaw, Civil Surgeon of Monghyr, has been appointed to officiate as Civil Surgeon at Cuttack. Major H. de Vere Condon has been appointed Agency Surgeon to the Native States of Kotah and Jhalawar. Major S. P. James, Assistant Director-General, has arrived home on leave of absence from India. Major W. S. Willmore has been appointed Civil Surgeon at Sitapur. Major E. A. C. Matthew has been appointed Honorary Surgeon to the Viceroy and Governor-General of the East Indies.

Captain P. S. Mills has been appointed Plague Medical Officer at Ambala. Captain H. J. Crossley has been appointed Specialist in Advanced Operative Surgery. The services of Captain H. A. H. Robson have been placed at the disposal of the Government of Bengal Presidency. Captain S. H. Middleton has been appointed to hold substantive medical charge of the 22nd Punjabis. Captain J. F. Boyd has been appointed on plague prevention duty at Benares. The ser- vices of Captain H. R. Dutton have been placed at the disposal of the Government of Bengal Presidency. Captain D. Fitz- gerald has been appointed to officiate as Superintendent of the Central Prison at Hyderabad. Captain H. Hallilay has been appointed Civil Surgeon at Lyallpur. Captain A. W. M. Harvey has been appointed Specialist in the Prevention of Disease to the Dera Dun Brigade. Captain J. F. Boyd has taken up duty at Ballia. Captain W. A. Mearns has been appointed to officiate as Superintendent of the Central Prison at Ahmedabad. The services of Captain D. D. Kamat have been placed at the disposal of the Government of Bombay.

Lieutenant D. M. Taylor has been selected for appointment as Specialist in Ophthalmology.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Cadet Thomas Warrington, from the London University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated March 25th, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st South Midland Field Ambulance, Royal Army Medical Corps: Henry Ernest McCready to be Lieutenant (dated Jan. 31st, 1914.

Welsh Clearing Hospital, Royal Army Medical Corps: Captain Ashley Bird to be Major (dated March 28th, 1912).

Attached to Units other than Medical Units.—Lieutenant Arthur H. Burnett resigns his commission (dated April 22nd, 1914).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The April issue of the *Journal of the Royal Army Medical Corps* opens with a communication contributed by Colonel Sir William Leishman, F.R.S., to the discussion on anti-typhoid inoculation[1] at the International Medical Congress held in London last year, in which he claims that anti-typhoid vaccine "has made its proofs" and is "worthy of general acceptance as the strongest weapon with which we can fight this deadly scourge of armies in the field." A joint paper by Major S. L. Cummins and Major C. C. Cumming deals with Experimental Typhoid Infections in the Rabbit, and a communication by Major P. H. Falkner supplies some interesting notes on recruiting duties, being a Few Details for Junior Officers of the Corps. Major H. A. L. Howell continues the Story of the Army Surgeon and the Care of the Sick and Wounded in the British Army from 1715 to 1748. In Leaves from a Notebook Colonel R. H. Firth gives us some more of his charming cogitations, discoursing pleasantly and instructively in the present instalment on such things as the chemical action of bacteria, the chemistry of the flower colours, the colouring matter of the yolk of an egg, the living cell and its nucleus, the nutrition of man, animals, and plants, organic compounds of arsenic and antimony, diseases caused by protozoa, crystallography and the physics of solids, the future supply of motor fuel and the origin of petroleum and asbestos.

The King has given to Captain Colin Cassidy, R.A.M.C., and to Captain William Edward Marshall, R.A.M.C., permission to wear the decoration of the Fourth Class of the Imperial Ottoman Order of the Medjidieh, which has been conferred upon them by His Highness the Khedive of Egypt, in recognition of valuable services rendered by them.

---

[1] THE LANCET, Sept. 6th, 1913, p. 735.

VICTORIA LEAGUE IMPERIAL HEALTH CONFERENCE AND EXHIBITION.—This conference will be opened in the Imperial Institute, London, at 3 o'clock, on Monday, May 18th, by the Right Hon. Lewis Harcourt, M.P., Secretary of State for the Colonies. The function will extend until Thursday, May 21st. The Dominion Government of Canada has appointed Dr. Helen MacMurchy as a delegate. The Hon. Sir John McCall, M.D., will represent Tasmania. The Union Government of South Africa has appointed as delegates Dr. A. W. Sanders and Dr. Gordon B. W. Messum. The British Medical Association of South Africa will be represented by Dr. J. A. Mitchell. The Leeward Islands have appointed Dr. H. A. Alford Nicholls, and Trinidad Dr. H. M. Alston as their representatives, and Dr. Atkinson is a delegate from Hong-Kong. On Tuesday, May 19th, the subjects of discussion will be Town Planning and Garden Cities and Suburbs, and Workmen's Houses and Model Dwellings. On Wednesday, May 20th, the subject will be the Care of Child Life, when papers will be contributed on Infancy and Health by Dr. David Forsyth; Sir Charles Mackellar, Australia; Dr. John McCulloch and Dr. Helen MacMurchy, Canada; and Dr. Truby King, New Zealand. There will be general discussion at every session of the conference, and popular addresses will be given daily in the Exhibition Hall. All particulars can be obtained from the office of the Victoria League, 2, Millbank House, Westminster.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 1143.)

XLIV.—LONDON: PANEL PRACTICE IN STEPNEY AND ENFIELD.

I NEXT proceeded to the East-end of London and called on a panel doctor with a large following at Stepney, an area which has always been in favour of the Act. In December, 1912, 26 practitioners from Stepney attended the pro-panel meeting held in Spring-gardens; in the course of January, 1913, 40 Stepney practitioners went on the panel; and now the profession is practically unanimous. This area is between Bethnal Green and Poplar. The district has a population of 278,000 inhabitants, and there are only 67 doctors in active practice. With three or four exceptions, they are all on the panel, and two of the practitioners who are not on the panel are over 60 years of age. There are some 93,000 insured persons in Stepney. The district is a distinctly Jewish one, and of the local practitioners a large proportion are of the Jewish faith and hold club appointments for the benefit of their co-religionists. Some of these were well worth having before the National Insurance Act came into operation, for the best among them paid their medical officer a capitation fee of as much as half a guinea per annum per member. A peculiarity among the Jewish population is that they like to consult several doctors; and those who could afford it belonged to several clubs and exercised the right of choice gained by the multiple payments. While some of the old clubs paid in Stepney very well in many instances, the practitioners have now lost not only the clubs but a number of private patients who have become insured persons. Nevertheless, there is no animosity against the Act. The security and the increase of income under the Act are held to compensate. Formerly, also, the East-end practitioner was badly hit by the hospitals and various institutions. After a private patient had called once or twice, if he found his case was serious he would seek admission to a hospital. To-day, whether such a patient succeeds or not in entering a hospital, his panel doctor does not suffer any financial loss. I was assured by my informant that the people at Stepney are appreciating the benefit of the Act, and that any feeling against the panel doctors which may have existed is dying out. The patients, it is true, when they found they had to take prescriptions to the chemists, complained of loss of time and the slowness of dispensing. But these services are now better organised.

Panel Practice in the Working at Stepney.

Here, as in other parts of London, a gratified surprise was expressed that there should be so few night calls. An informant told me that out of the 1850 insured persons on his list during the whole year only two had called him out at night. The visiting also had been comparatively light among the panel patients, and it seemed to him that the paying patients sent more frequently. His good fortune must be considered exceptional, as he had not lost as many private patients as he had expected, but his case is not that of every practitioner in Stepney.

As there are many dock labourers and carmen in the district, there are numerous cases of minor surgery. The injured generally obtain a first dressing at the nearest hospital, but for subsequent care are referred to their panel doctors, and some of these patients entail visiting and dressing of wounds over long periods. But a great deal of help is obtained in such cases from the district nurses. The East London Nursing Society notably renders great service. The patients, unless they are very poor, make a donation to the nursing institution.

I had already come to the conclusion that when a panel doctor has his list made up in the main of his old patients he is not likely to be troubled very often, and what I learned in Stepney confirmed the view. The new doctor, unknown to the patients, and perhaps unfamiliar with the routine of club practice, dealing with newly insured persons, ignorant of the rules, has far and away a worse time than his experienced colleague. In short, experience teaches.

The Panel and the Women Workers.

I found that a large number of women in Stepney are now receiving medical advice who had never seen a doctor before the Act came into force. This also applied to some of the men, but was more general among women, who do not seem to make easy patients. There are many women working in tobacco and other factories in Stepney, and if such conditions as leucorrhœa or varicose veins are not unduly common among them, dyspepsia and constipation seem almost universal. The Jews, who are much more careful over their food, do not suffer so much. Anæmia is also very common, and a great deal of good is now being done by taking these complaints in hand early. In other quarters of London which are less poor, and where there is a mixture of residential and working-class population, the accounts given me of the insured women patients have differed somewhat from what I heard at Stepney. When a larger proportion of women is employed in shops varicose veins are more frequent, and also temperamental troubles to which I may make only this allusion—many women in this class bear responsibility badly; as hard worked and perhaps lowly paid assistants they enjoy good health, while as manageresses they break down.

Popularity of the Panel in Enfield.

I have selected Stepney for treatment as a type of a district occupied by a purely industrial population, but I found that the popularity of the Act was a feature also of Enfield, on the outskirts of the metropolis. There are many places just beyond the metropolitan area where the inhabitants are to a certain extent Londoners. They frequent the London shops, the London theatres, and occasionally consult the London physicians. Nevertheless, they have their local life, which is better developed than the local life of the London boroughs. Of such places Enfield is a type. A few county families still reside in the neighbourhood, and there are opportunities for good general practice among the middle classes. Several Enfield practitioners have as many private patients as insured persons to attend, and as usual the balance has to be struck between the loss from private patients becoming panel patients and the gain of regular returns.

The Enfield area is under the Middlesex Insurance Committee, and there are here 24 practitioners who at first were very determined to fight the Insurance Act. But the unanimity of action did not last long. Possibly political aggressiveness on either side led to disunion. Anyhow, those who wanted to treat the question on its own merits and not as a matter of party politics refused to follow the lead of those whom they regarded as party politicians, while those who had given pledges to resist the Government began to suspect themselves pawns in a political game. On Dec. 16th, 1912, a circular was sent round by two Enfield practitioners stating that, in their opinion, the time had come to accept service under the Act and inviting all the local members of the profession to a discussion, bearing in mind that the profession was not sufficiently unanimous to prevent the formation of a Government Medical Service. It was the old situation which I have so often described.

In response to this circular meetings, prolonged till midnight, were held and personal attacks were made. In the end, however, all decided to go on the panel, since when there has been no hostility between the members of the profession at Enfield, who in particular rejoice at their present freedom from the control of Friendly Societies.

The Question of Malingering.

This question has given rise to considerable trouble at Enfield; it is, indeed, the outstanding difficulty in the working of the Act here. At Enfield I found that the Workmen's Compensation Act was largely held responsible for the apparent excess of sickness. The victim of an accident has to suffer for a fortnight to claim compensation, so he does not want to be cured just two or three days too soon. Also, though injured, a workman may go back to light work. If he refuses to do this the employer may resent his attitude; if he does go back he is likely to lose his claim for compensation. Some workmen escape from this dilemma by exaggerating the symptoms and pretending to be too ill to undertake even very light work. So far as the law is concerned it is much better not to go back to work at all till the case is settled.

If in such cases the panel doctor regards the real condition of the patient he is likely to find himself in conflict with the insurance agent. It may be thought that the latter is particularly anxious to prevent malingering, as it costs the company he represents the sick allowance paid. This is so to a large extent when the agent represents a Friendly Society. In that case both agent and patient are partners in the society, and are therefore interested in not overtaxing their own reserve funds. But where the insurance companies act as Approved Societies neither agent nor patient is concerned in saving any money. The agent is not a partner, he has no share in the profits of the concern, but he is paid by results. The more insured persons he gets on his book and the greater the regularity of the payments they effect the larger the commission he earns. Therefore it is to the interest of the agent to be as popular as possible, and consequently he only ventures to denounce very flagrant cases of malingering. Much of the malingering is only for a short time, just to obtain a week's holiday or a few days in which to substantiate a claim under the Compensation Act. An agent who would prevent a wounded workman from getting compensation would very soon lose his popularity and livelihood.

The Bribing of Insurance Agents.

In this connexion I heard an ugly rumour which I think it my duty to repeat. I heard it—I cannot prove it. Some of the agents desire to add to their incomes by obtaining payment from the panel doctors in return for persuading insured persons to place their names on the doctors' lists. This shameful state of affairs, I was assured, prevails on a larger scale than it is pleasant to contemplate elsewhere, though my attention was drawn to it at Enfield. In these circumstances, not only are newly insured persons canvassed for, but some who were already on other doctors' lists are persuaded to transfer. The dodge employed has been, as described to me, as follows. The agent acquires some knowledge of the symptoms of various diseases, and having ascertained what is the complaint of an insured person, he professes to have had the same disease himself; and while describing the symptoms tells a wonderful story of his rapid cure by "Dr. X Y Z." The sufferer is then likely to express his regret at not being on Dr. X Y Z's list, when out of the agent's pocket come transfer forms, and out of his mouth an offer to undertake all the formalities necessary to effect the change: and thus he earns a commission from the panel doctor, and also, of course, from the insurance company if the patient is not already on their books. That medical men should stoop so low as to offer agents commissions to get them patients is very humiliating. The possibility has been hinted at in my presence on more than one occasion; but at Enfield I received more than a hint.

The Panel Approximating to Private Practice.

To turn from this unpleasant aspect of the subject, I was assured that none of the practitioners at Enfield had been hurt by the Act. Those who had been most opposed to the Act were now willing to remain on the panel. The patients, on their side, had largely benefited. Many diseases, notably pneumonia, had been taken in time, lives saved, and much mischief prevented. A very considerable number also of women were insured, and for the first time in their lives were receiving medical advice. I did not meet with any expression of opinion that favoured a State Medical Service. The Act had proved, in the opinion of the men of Enfield, more advantageous than was thought possible, and no desire for any sort of radical change was expressed, though improvements on minor points were required. The general practitioners at Enfield are now quite united. They are all on the panel, so there is no contest between the panel and non-panel doctor.

(*To be continued.*)

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.—The thirty-first annual general meeting of this society was held in the rooms of the Medical Society of London on April 2nd, under the presidency of Dr. F. J. Allan, chairman of the executive committee. The chairman drew attention to the satisfactory state of the society's affairs, which was indicated by the fact that the membership had increased by 78. The total amount paid out in sickness benefit during the year was £19,354, while the premiums received amounted to £20,726. The total funds of the society amounted to £255,350, and during the past year the working expenses had amounted to 6 per cent. of the premium income, which he thought showed great economy in administration. The quinquennial valuation showed, in his opinion, a satisfactory state of affairs. The society was flourishing and in a perfectly sound state and would be able to continue the bonuses which it paid at death or on attainment of 65 years. A subcommittee had been appointed to recast the rules, which in their new form were submitted to the meeting. The report of the committee and the audited accounts for 1913 were adopted. The motion that the quinquennial valuation report be received was carried with one dissentient. The proposed new rules were taken seriatim and adopted with certain amendments. The meeting concluded with the election of officers and a vote of thanks to the chairman.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

MANCHESTER.

The Summer Term at the University: Earlier Graduation.

THE summer term at the University began on April 20th. For the first time in the history of the medical faculty in 1913 the graduation day at the end of the summer term coincided with that of the other faculties at the beginning of July. In former years the medical graduation took place after that of the other faculties—towards the end of July. This year this precedent will be followed, and graduation in all faculties will take place on July 4th. In order to obtain sufficient time for the work during the summer term, the term itself begins now just after the middle of April. The winter session of 1914 will commence on Oct. 8th, some days later than usual.

Donations and Gifts to Salford and Jewish Hospitals.

The board of management of the Royal Salford Hospital in their annual report announce that the gift of £5000 promised by Sir William Mather has led to £5500 as additional subscriptions being secured, whereby the board was able to complete the whole of the large extensions commenced in 1906 without any encroachment on the invested funds of the charity. The legacies during the year comprised one of £3100 made by the late Professor Dixon Mann and another of £560 from the late Miss Ann Meredith. The contributions from workpeople amounted to £250, being a decrease on the preceding year. The Victoria Memorial Jewish Hospital a short time ago made an appeal for £10,000. Already £6500 have been obtained or promised. A memorial tablet to the late King has been placed in the hospital, and a ward is specially named the King Edward VII. Ward.

The Provision of Radium in Manchester.

The Manchester radium committee held a meeting on April 20th at the Town-hall, and approved a draft scheme for the provision of a supply of radium for the city and the surrounding districts. The following hospitals will coöperate: the Manchester Royal Infirmary, the Christie Hospital, Salford Royal Hospital, Ancoats Hospital, the Northern Hospital, St. Mary's Hospitals for Women and Children, and the Hospital for Diseases of the Skin. The radium will be stored at the Royal Infirmary and patients will be treated there, but radium being required at any of the other hospitals application can be made to the central depôt. It is proposed to establish a radium department with an expert radiologist as its head. An appeal for funds will be issued shortly. Substantial additions have been made to the Radium Fund since my last report on this question in THE LANCET of Feb. 28th. The total amount has now reached £4317. The Manchester board of guardians has also taken up the matter so far as relates to the question of providing radium for the treatment of cancer cases in the Poor-law infirmary. There are at present in the infirmary 24 such cases. The South Manchester board of guardians has passed a resolution that, subject to the consent of the

Local Government Board, radium to the value of £2500 should be purchased and that the Local Government Board should be asked to allow the guardians to borrow that sum, to be repaid during a period extending over 30 years. A similar application will be made in respect of an X ray apparatus, the loan to be repaid in 15 years. During 1913 there were 123 cases of malignant disease in the South Manchester hospital.

Excessive Sickness Claims by Women Employed in the Textile Industries of Lancashire and Cheshire.

The excessive sickness claims under the National Insurance Act by women, particularly amongst the textile workers of Lancashire, have attracted much attention. The Textile Operatives' Approved Society, with 65,385 women workers, paid for sickness in six months £24,000, an excess above the actuarial estimate of £10,500. During the six months the payments amounted to an average of 7*s.* 6¼*d.* as against the actuarial estimate of 4*s.* 4*d.* per member. From a report obtained from the secretary of the Manchester Unity of Oddfellows—which has 872,608 members, 704,950 men and 167,653 women, in all parts of the United Kingdom—we learn that the payments in the various parts of the Manchester Unity have been on the average, including both men and women, England 7*s.* 9*d.*, Scotland 6*s.* 11*d.*, Wales 9*s.* 9*d.*, and Ireland 5*s.* 2*d.* per member. It appears that sickness claims are much heavier in Wales than in other parts of the United Kingdom, which is said to be the experience of all Friendly Societies. An analysis shows that Lancashire and Cheshire are in excess of the expectation so far as women are concerned, while the figures for men are all below the expectation:—

	Actual cost.	Actuarial estimate.
Sickness claims of men (nine months):		
Lancashire	8*s.* 11*d.*	9*s.* 9*d.*
Cheshire...	8*s.* 4*d.*	9*s.* 9*d.*
Sickness claims of women (nine months):		
Lancashire	8*s.* 8*d.*	6*s.* 6*d.*
Cheshire...	7*s.* 4*d.*	6*s.* 6*d.*

The excessive sickness claims in these two counties are attributed to the large proportion of married women working in the mills.

April 21st.

SCOTLAND.

Royal Visit to Glasgow.

ACCORDING to the provisional arrangements made for the visit of the King and Queen to Glasgow on Tuesday, July 7th, their Majesties on arrival in the forenoon will proceed to the Royal Infirmary, where the new buildings will be formally opened. The King will then lay the foundation-stone of the extension of the municipal buildings, and will be entertained to lunch in the city chambers by the corporation. At the conclusion of lunch their Majesties will be escorted to the Royal Hospital for Sick Children, at which the opening ceremony of the new hospital will be performed. The next item on the programme is a visit to the Western Infirmary, where at the main doorway their Majesties will receive an address from the managers. Afterwards the Royal visitors will drive through the grounds of the University on their way to the central station to entrain for Edinburgh.

Radium for Glasgow.

The movement started recently for the purpose of securing a supply of radium for Glasgow was advanced a stage last week at a meeting of influential citizens held in the Merchants' House, under the presidency of Sir John Stirling-Maxwell. The case was very well put by the chairman, who drew attention to the extreme costliness of radium. It never would be cheap, he said, but it was calculated that in future years its value might fall by one-half. It was also possible that other and cheaper methods might be discovered of obtaining the coveted rays which radium projects. Therefore, there was a measure of business risk in the purchase. Radium itself deteriorated so slowly that there was no objection to be raised to the scheme on that score. In 2000 years its power might be diminished by half, and a sinking fund of a few shillings could meet that contingency even for a purchase on a large scale. From the scientific and philanthropic side everything was to be said for a rich city like Glasgow having a supply of the new healing agent. The Senate has agreed to put a room at the University at the disposal of the committee, and to allow Mr. Soddy, who is one of the first authorities on radio-activity, to take general charge of it. The amount the committee has been advised to purchase is 300 milligrammes, and this would be available for the hospitals, and under certain conditions for private practice. Its use would be controlled by a committee of medical men, and a specialist would have to be employed to take immediate charge of it. The sum aimed at by the committee is £8000 or £9000.

School Children in Inverness-shire.

The annual report on the medical inspection of school children in the county of Inverness is an interesting document containing as it does many references to the general state of public health in the Highland area. According to the report, while many school boards, on whom lies the onus of seeing that treatment of defects is carried out, have been endeavouring to afford treatment to necessitous cases, as a matter of practice this has been found to be impossible to any great extent in the county, the sums provided by Government for the purpose being totally inadequate, if individual boards are to deal effectively with all the cases brought under their notice, while attempts at combined effort have also failed. In the remoter districts much difficulty is experienced in obtaining medical and nursing attendance. The need for specialised medical services in the Highlands is seen from the number of children with defective teeth and eyesight, and other conditions requiring the services of a specialist. Dealing with the question of feeding the school children, one of the medical officers says: "It is simply cruelty to send a child of five or six or seven years a distance of two or three miles to school in wintry weather with no other sustenance than a piece of dry oatcake, barley bread, or scone, with the prospect on arriving home at 4 o'clock of getting a solid meal—oftener not." He describes the children as "wiry," and remarks, "No wonder they are wiry."

April 21st.

TAUNTON AND SOMERSET HOSPITAL.—The committee has decided to carry out extensive additions to the Taunton and Somerset Hospital at an expenditure of £2063. A new operating theatre, with sterilising and anæsthetising rooms, is to be erected, and the children's ward is to be enlarged. The work will be commenced shortly.

IRELAND.

The Women's National Health Association.

THE annual meeting of the Women's National Health Association was held last week in Dublin under the presidency of Lady Aberdeen. Reports were presented dealing with the various activities of the association. A pavilion to accommodate 60 children will soon be completed at Peamount Sanatorium. The association has now 155 branches and 19,000 members.

The Dublin Housing Question.

The speech of the Chief Secretary to the Lord Lieutenant of Ireland in the debate in the House of Commons last week on the housing of the working classes of Dublin has caused considerable disappointment. Mr. Birrell a few months ago was in such a hurry to get to business that he would not hear of the appointment of a Vice-Regal Commission, but now he is all for delay. Having prevented, in his anxiety to deal with Dublin, any evidence being collected concerning other towns, he now thinks "it would be very difficult to make grants to Dublin and refuse them to other towns in Ireland." Mr. Birrell's speech seems to have shelved the report of the Departmental Committee. The unfortunate fact is that last November the public gaze was directed to Dublin, and now it is directed elsewhere, and the slums are to remain with us.

Epidemic of Measles in Dublin.

Dublin is at present suffering from a serious outbreak of measles, a disease which is not notifiable in the city. In four weeks there have been 102 deaths from this cause, and on April 11th there were 148 cases in the city hospitals. The disease is of a virulent type. Many of the deaths are among children who have suffered hardship in the recent industrial dispute. The general death-rate in Dublin has been alarmingly high for some weeks; in the week ending April 11th it reached 287 per 1000.

Sir Christopher Nixon.

I am informed that the report of the impending retirement of Sir Christopher Nixon from the active staff of the Mater Misericordiæ Hospital, to which I gave publicity last week, is incorrect. The distinguished physician has had a severe attack of influenza, from which there has been a retarded convalescence. He hopes, however, to take part in the work of the current session.

City Rates in Dublin and Belfast.

Last year the Dublin city rates amounted to 10*s.* 4*d.* on the north side of the city and 10*s.* 1*d.* on the south side. The rates which have just been imposed for the current year are 11*s.* 5¼*d.* on the north side and 10*s.* 9¼*d.* on the south side, being an increase of 1*s.* 1¼*d.* in the one case and 8¼*d.* in the other. In Belfast last year the municipal taxes (including Poor- and water-rate as in Dublin) were 7*s.* 1*d.*; this year they are 7*s.*

Scarlet Fever in Belfast.

There has been a further recrudescence of scarlet fever in Belfast, 52 cases having been notified during the week ended April 11th, as compared with 42 cases in the previous week and 25 cases in the corresponding week of last year.

Remarkable Weather for April.

It is many years since we had such warm weather in April as we have been experiencing during the past week in the north of Ireland, but unfortunately, owing to the want of any advance in road-making, the dust nuisance has become a veritable danger to health. Indeed, a cause of the sickness incidence in Belfast may well be the clouds of dust present in dry weather.

Poliomyelitis in County Tyrone.

I regret to report a further outbreak of acute poliomyelitis on the Tyrone shores of Lough Neagh. During the past week, in a farmer's house, the father, mother, and six children have been attacked, and two of the children—a boy aged 9 years and a girl aged 3—have died, while all the others are in a critical condition. It is really time the Local Government Board made some scientific investigation of these repeated outbreaks of this disease in Tyrone.

April 21st.

PARIS.

Proposed New Legislation as to the Care of the Insane.

MANY books, novels, and plays have been based on the supposed danger in France for a sane person of incarceration as a person of unsound mind at the instance of the family or heirs and from interested motives. Such cases have been very rare. Nevertheless, a Bill has been introduced into the Senate by M. Strauss to increase the discretion of the magistrates in such cases at the expense of that of the medical profession. This Bill, referred for consideration to the Académie de Médecine by the Ministry, provides that within three days of a committal the court must be advised thereof. When such committal has lasted for six months it may be made definite by judgment of the court. Nearly all alienists have protested against these provisions, and the Academy has now received from Professor Thoinot the report of its special committee of inquiry, which advises the rejection of the new provisions and recommends the continuance of the existing law with slight modifications. In support of these conclusions, M. Gilbert Ballet showed that the new law, in its desire to protect an insane person against arbitrary confinement, subjects him, and especially his family, to a greater wrong. Many patients now provisionally confined are cured in a few weeks by isolation and appropriate treatment, and return to civil life without the cause of their temporary absence being suspected, protected as they are by the secrecy of the medical profession. But the intervention of a court in the first three days would make the situation known to a *personnel* of magistrates, clerks, and employees under no such pledge of secrecy, whose lack of discretion, especially in small places, might compromise the moral and material position of the patient, and in the case of a woman her reputation, her chances of marriage, and her position in her family. Many families having members needing care would recoil before the publicity involved, and would send the patient to less exacting foreign institutions, especially those of Switzerland. As to the subsequent decision of the court after six months to prolong the confinement of those adjudged dangerous to themselves or others, it would amount to a sentence of imprisonment by an authority incompetent if the court alone decides, and useless if the court is merely to register the hitherto sufficient decision of the medical expert, while importing the harmful element of publicity. M. Ballet holds that so far from deserving the ignorant censure of novelists for their arbitrary rigorousness, the medical officers of asylums have too often prematurely released insane persons temporarily improved by isolation and quietude. He cited the case of one person three times confined and released on the demand of his family, who on each release had committed a murderous assault (*assassiné une personne*). M. Ballet urged that even when the asylum fulfilled the function of a prison in preventing the insane person from doing mischief it should preserve its medical character and remain under medical control. M. Magnan, physician to the Asile Ste. Anne, stood alone in favouring the new Bill.

The Bath as a Mode of Vascular Gymnastics.

M. Dausset and M. Henriot recently reported to the Académie de Médecine some original investigations on the use of baths to restore elasticity to the peripheral vessels. They put the patients into a bath at 98·6° F., which was then gradually raised to 113°, and slowly lowered to 86° and even to 68°, according to the tolerance of the patient. The peripheral vessels thus undergo a mild but energetic vaso-dilatation followed by vaso-constriction, which restores the vascular elasticity in arthritics and regulates irregularities of arterial tension. The treatment appears to be without danger, and those submitted to it learn to sustain without discomfort huge variations of temperature in a few minutes. The variations of tension must be controlled by the pulse during the procedure.

The Congresses.

Eastertide is the season of special congresses. Cannes, has recently been the meeting place of a Congress of Thalassotherapy, its entire session being devoted to the study of marine heliotherapy. Professor Albert Robin presided. At Paris the Congress of Physiotherapy of French-speaking Physicians and the Congress of Learned Societies have taken place simultaneously. The last named devoted only one meeting to medical science. Dr. Magnan and Dr. de Lariboisière reported to it an ingenious method of estimating the superficies of the human body. They covered the entire body with a layer, as thin as possible, of a mixture of 26 grammes of white lead and 100 grammes of linseed oil. The person thus treated is weighed, and this weight compared with that before the application of the layer gives the quantity of the material of the layer. The weight of the material requisite to cover a square decimetre having been determined accurately by very many experiments, the entire surface covered by it on the body can be ascertained with some accuracy. The Congress of Physiotherapy was professionally the more important. Under the presidency of Professor Maurel, of Toulouse, many French and foreign medical men—especially Belgian, for the congress was organised conjointly with the Societies of Radiology and Electrotherapeutics of Brussels—were assembled. Among those present were Dr. F. Howard Humphris and Dr. Cyriax, of London, Dr. Salomonson, of Amsterdam, and Dr. Edmundo Xavier, of Rio Janiero. Professor Landouzy, in opening the congress, counselled physiotherapeutists to study with precision the real causes of the conditions they treated before choosing the particular physical measure appropriate to the case. M. Maurel reviewed recent progress in regard to the physiological action of the principal agents of physical therapy, light, heat, cold, various radiations, &c. The following subjects were on the order of the day: the rôle of various physical agencies, and particularly of movement, in psychasthenias, the physical agents in gout, ankyloses, myopathies, lupus vulgaris, and ptoses. Of individual communications a large number dealt with the treatment of cancer by physical agents. Particularly noteworthy was a communication from Dr. Doyen, who denied any value in this respect to radium and the X rays, which he accuses not only of being useless, but even of favouring the development of the neoplasm. In his opinion the only efficacious treatment consists in local elevation of temperature to a point that kills the cancer cells selectively, the healthy tissues remaining unaffected. To this end the high-frequency current is most useful. The congress concluded with a kinematographic demonstration by Professor Bergonié, of Bordeaux, of the physiotherapeutic methods of treating infantile paralysis, especially such methods as permit the exercise of walking. There was an important exhibition of newly invented apparatus for physical therapy.

April 20th.

VIENNA.

Large Donations for Charitable Purposes.

WITHIN the last four weeks we have had the pleasant but too unusual experience of learning that wealthy men have been giving away large sums of money for philanthropic purposes in this city. One donor has given 300,000 kronen (£12,500) for the care of mothers and infants, which sum will be handed over to the institute erected some time ago with the object of reducing the mortality of infants. Another sum, which will exceed 1,000,000 kronen, is the gift of a well-known politician who is retiring from public life and is desirous of conferring substantial benefits on nine of the chief charitable institutions of Vienna, including the Hospital for Incurables, the Free Ambulance Corps, and the Cancer Hospital. The conditions of this gift are such that the whole of the money will be devoted to relieving patients of the poorer classes, and care has been taken to guard against the Government pursuing its usual policy of appropriating large sums from these charitable grants in the shape of rates and taxes. In a third instance a tailor who had made a fortune in his business has presented the Wilhelminen Children's Hospital with 3,000,000 kronen and a large estate in a rural district. Hitherto the numerous children who have been treated in the hospital for any infectious disease—such as measles, diphtheria, scarlet fever, or any other infectious disease—have on their recovery had to return to the unhealthy surroundings of their homes, but this munificent benefactor now wishes these children to be sent from the Wilhelminen Children's Hospital to the country for convalescence. There has not until now been any satisfactory method of dealing with the young convalescents at this hospital, which draws its patients from the poorest classes of the population; but in future the generous gift which has been placed at the disposal of the institution will enable about 600 children every year to spend at least four weeks in the country.

Government Provision for Tuberculous Patients.

The Government has ordered a sum of 1,000,000 kronen per annum to be employed for the next ten years in order to provide institutions for the treatment of tuberculous patients. Really effective places of this kind are rather uncommon in this country; in fact, with the exception of several small private establishments which are decidedly expensive, there is only one in Alland into which the poorer part of the population can try to obtain admission; it has accommodation for 150 patients, with a children's pavilion containing 64 beds. This institution will now be enlarged by about 100 beds, and in several other suitable places all over the empire such sanatoriums will be erected. Furthermore, in Tyrol the Government has begun the building of a "sunlight" treatment institute according to the system of Dr. Rollier, at Leysin, in Switzerland. It will be at an altitude of over 6000 feet above sea-level, and will be devoted chiefly to the treatment of surgical tuberculosis. By this method results successful beyond anything that could have been expected have been obtained, but it must be added that the recovery is slow, and that from one to two years of constant open-air life may be required.

The New Income-tax Regulations and the Medical Profession.

At the beginning of the present year new income-tax regulations were adopted by Parliament, and some of the items are of great interest to the medical profession. Whilst the limit of exemption from taxation has been slightly raised (1600 kronen, or £66), the general percentage of the tax has been raised by an amount varying from about 2 to 5 per cent. In future every person having a taxable income must make a correct return of it to the officials, and if intentional misstatement is discovered the delinquent may have to forfeit a sum equal to 10 times the amount of the tax. All medical men connected with private surgical homes, sanatoriums, and the like will have to inform the officials as to the number of operations performed there and as to the fees received by the medical advisers, who will also have to show their books in disputed cases. This will raise questions of professional secrecy and the medical corporations are taking action for the purpose of remedying such grievances. One section of the new regulations provides that the income-tax of bachelors and spinsters shall be increased by 15 per cent., whilst married couples without children or with only one child will have to pay 10 per cent. more than the ordinary tax; families with four or more children may claim a deduction of about 5 per cent. per child if the children are living with their parents.

April 2nd.

UNITED STATES OF AMERICA.

Bills to Legalise the Practice of Osteopathy and Christian Science in New York State.

Two Bills have just passed the Legislature of New York State which are likely, if they receive the Governor's assent, to do great harm. One of them will relieve Christian Science practitioners of the fear of prosecution if their patients die under treatment, and will place the practice of Christian Science on exactly the same plane as that of medicine or surgery, and incidentally will favour the extension of infectious diseases. The other Bill is intended to place the osteopath on practically the same footing as the regular practitioner of medicine. The medical profession of the State is up in arms against the Governor signing these Bills, and it is hoped that sufficient influence may be brought to bear upon him.

Pellagra.

The Thompson-McFadden Pellagra Commission of the New York Post-Graduate Medical School and Hospital a short time ago issued its "first progress report" on its investigation of the disease in the Southern States. While the Commission has failed so far to discover the specific cause of pellagra, its investigations seem to point to the fact that it is transmitted by the stable fly. The members of the Commission do not agree with Professor Louis Sambon, of the London School of Tropical Medicine, that pellagra is transmitted by the simulium (buffalo gnat), but with him they reject the theory that spoiled maize is the essential cause of the disease, which has attacked at least 50,000 residents of the Southern States. As to the infectious nature of pellagra, the Commission considers that the higher incidence of it in the more populous districts, the indications of its occurrence in definite foci, and the definite tendency to self-limitation of the attack in the absence of specific therapy and during continuance of a maize diet, strongly support this conception. A comprehensive consideration of the insect life in Spartanburg County, South Carolina, where the investigations were undertaken, suggests that, if the distribution of pellagra is to be accounted for by a blood-sucking insect, the Stomoxys calcitrans is the most probable insect carrier. Congress has authorised the establishment of a hospital at Spartanburg for the care and study of patients with pellagra.

National Committee of Mental Hygiene.

At the sixth annual meeting of the National Committee of the Society for Mental Hygiene, held in New York on March 10th, Dr. Lewellys F. Barker, professor of medicine at Johns Hopkins University Medical School, was elected president; Dr. William H. Welch, Baltimore, vice-president; Dr. Thomas W. Salmon, New York, director of special study; and Mr. Clifford W. Beers, New York, secretary.

The Study of Animal Diseases.

It has been announced that Mr. John D. Rockefeller has given $1,000,000 for the purpose of studying the diseases of animals. This gift is timely in view of the recent activity of the anti-vivisectionists in the United States, and especially in New York.

The late Professor Joseph D. Bryant.

The United States loses one of its prominent surgeons through the death in St. Vincent's Hospital, New York, on April 7th, of Dr. Joseph D. Bryant. Dr. Bryant had suffered for some time from diabetes, to which complaint, I understand, he succumbed. Joseph Decatur Bryant was born in 1845 at East Troy, Wisconsin, and was therefore 69 years of age. He received his early education at the Norwich Academy in New York, and his medical education at the Bellevue Hospital Medical College, where he graduated as M.D. in 1868. He became an interne at Bellevue, and in 1871 was appointed assistant to the chair of anatomy. From that time he held several professorial posts there in succession in anatomy, general and surgical, clinical and orthopædic surgery, and, on the amalgamation of this medical school with that of the New York University in 1898, he became professor of surgery to the conjoined schools, which post he held up to the time of his death. He had filled many important offices, among them health commissioner of the city of New York, president of the New York Academy of Medicine and of the American Medical Association, and Surgeon-General of the State of New York. He was a Fellow also of the newly established American College of Surgery.

He published a valuable work on operative surgery, and the concluding volume of the "American Practice of Surgery," which he edited in conjunction with Dr. Albert H. Buck, was reviewed in THE LANCET with great commendation of the entire work.

The Death of Dr. Egbert Le Fevre.

Dr. Egbert Le Fevre, of New York, died on March 30th, after four days' illness, from scarlet fever, and his sudden death has come as a shock to all his friends. He was of French Huguenot origin, the son of James Le Fevre, D.D., was born in Raritan, New Jersey, on Oct. 29th, 1858, and was educated at Rutgers College School, New Brunswick, New Jersey. He graduated in arts at Rutgers College in 1880, and in medicine at New York University in 1883. He became visiting physician to City (Charity) Hospital of New York in 1895. He was also dean of New York University and of Bellevue Hospital Medical School, attending physician to St. Luke's and consulting physician to Beth Israel Hospitals. He had already held various professorships at the Medical College of New York University, when, on the consolidation of this institution and Bellevue Hospital Medical School in 1898, he became professor of clinical medicine and therapeutics there. He was a Fellow of the New York Academy of Medicine. Dr. Le Fevre was a man of imposing presence, upwards of 6 ft. 4 in. in height, and large in proportion. He was exceedingly popular, and had one of the largest consulting practices in New York City.

April 2nd.

INDIA.

Sir Arthur Sloggett's Farewell.

IN a circular memorandum bidding farewell to the medical services in India Sir Arthur T. Sloggett conveyed his thanks to all the administration and executive officers of both the Royal Army Medical Corps and the Indian Medical Service for the loyal support and coöperation extended to him by all ranks, and stated that he carried away with him the happiest recollections of the six years he had spent in the country.

Extension of Tenure of Director-General, I.M.S.

Surgeon-General Sir C. Pardey Lukis, K.C.S.I., has been offered and has accepted an extension for two years of his tenure of Director-General, Indian Medical Service, which would otherwise expire on Dec. 31st, 1914.

Control of Leprosy.

The Secretary of State has sanctioned the strengthening of the bacteriological department by 15 new appointments.

Tuberculosis in India.

At the Lucknow Sanitary Conference in January last it was decided that in view of the present prevalence of tuberculosis in India serious attention and special measures for dealing with the disease were demanded, and that one or more officers should be placed on special duty to study in detail the different problems connected with it. It is understood that arrangements are in progress for the employment of Dr. A. C. Lankester, who has given special attention to this particular subject, for the investigation, and he will shortly start a tour throughout India with this object. He will give lectures and make general inquiries into the prevalence, distribution, and special causation of the disease in India. At the conclusion of this tour he will prepare a special report embodying the results of his inquiries for the information of the governing body of the Indian Research Fund Association, which is financing the scheme.

School of Tropical Medicine, Calcutta.

At a recent meeting of the Calcutta municipal corporation a resolution was adopted reducing the amount of contribution to hospitals by one lakh of rupees and reserving that amount for contribution to the hospital proposed to be attached to the School of Tropical Medicine.

Appointment of Serologist in Calcutta.

The following press *communiqué* has been issued by the Home Department: In recent years much progress has been made in applying biochemical tests to the origin of blood stains, and these have been found to be of great value in medico-legal practice for some time. Lieutenant-Colonel W. D. Sutherland, I.M.S., has been working on the subject in Calcutta and training others in his methods. The results achieved have been such as now to justify more formal arrangements, and it is proposed to employ Lieutenant-Colonel Sutherland for a period of two years in the first instance as a serologist in Calcutta to whom cases may be sent from any part of India. The work is of an expert character and demands special equipment and facilities. It is thought that it will be performed more expeditiously and satisfactorily by one officer than at different provincial centres.

Pure Milk for Bombay.

A company has been registered in Bombay with a capital of a lakh of rupees for the supply of pure sterilised milk. Mr. Ratan Tata is chairman of the directors of the new company. Shares have been privately subscribed and the object is a philanthropic one, being to enable the residents of Bombay to secure milk guaranteed to be pure. It is not proposed to attempt to supply the whole of the city, but an effort will be made to supply milk required for infantile consumption. It is proposed to establish near Bombay, and probably in the Salsette district, a dairy farm with some four acres or so of grass land, and on the farm there will be one or more stables or cowsheds erected on up-to-date sanitary principles with sufficient accommodation for 100 animals.

Leprosy in Bombay.

The Government of Bombay has just issued a short pamphlet entitled, "Leprosy and its Control in the Bombay Presidency." The pamphlet first quotes the latest expert opinion on the degree of contagiousness of the disease, and defines the limits within which restrictions on and segregation of lepers are justifiable. It next sketches the Lepers Act, and explains how it has been applied to a large number of the municipal districts in the Presidency proper. It details the measures taken to provide accommodation for lepers in new asylums and by enlarging and improving existing asylums, and shows that special attention is to be paid to the care of the untainted children of leprous parents. Finally, mention is made of the machinery necessary for the working of the Act.

Madras Hospital Removal.

The Government of Madras in a recent Order has directed the removal of the General Hospital and Medical College, Madras, from their present site and reconstruction on the Spur Tank, which "satisfactorily fulfils the conditions required and, indeed, affords the only solution of the problem."

Plague Passports.

It is understood that the Madras Government contemplate the abolition of the plague passport system in the near future, and the introduction in its place of a system under which people arriving from infected areas will be required to notify local authorities of their arrival. The matter is now engaging the attention of the Government.

Plague in Bihar.

Reports received by the press and from private sources state that plague is playing havoc in many of the towns and villages of Bihar, and there is quite a panic among the people owing to the virulent form in which it has broken out. This year the visitation appears to be worse than ever before.

Plague in the Punjab.

Mortality from plague in the Punjab has steadily increased during the current month. There were 2314 cases with 1702 deaths in the week ended March 14th. Every district except Lahore is now infected.

Agra Medical Students' Strike.

The medical students at Agra struck on March 15th. They left the hostel and passed the day and night in open spaces. Maltreatment is alleged to be their chief complaint. The authorities deny the students' version, and say that they were in the dark as to this development, which took place with great suddenness and secrecy. Until evening the students were playing games, and there was no inkling of any grievances on their part. The authorities believe this to be connected with the Lahore medical students' strike, but cannot give any definite cause with certainty.

Successful Use of Storaine at Bangalore.

Two successful major operations have been performed by Major R. F. Standage, residency surgeon at Bangalore, who used the spinal anæsthetic known as stovaine, in the presence of the local surgeons. Major S. G. S. Haughton, R.A.M.C., who is travelling through India to familiarise the hospitals with the use of the drug, demonstrated the technique to the meeting.

March 18th.

"Audi alteram partem."

THE RELATION OF TUBERCULOSIS AND TYPHOID FEVER.

To the Editor of THE LANCET.

SIR,—I should like to make a short comment and criticism on the annotation in THE LANCET of April 4th with the above heading, to which my attention has been drawn.

Without an actual record of the figures of my cases and of those of my colleagues at the London Hospital it would be rash to deny that tuberculosis ever follows typhoid so closely that its onset and development can be attributed directly to the influence of the typhoid, but I cannot recall to mind any such case having occurred, and I should require details of a large number of cases before being convinced of such a sequence between the two diseases. If, however, such a sequence has been observed by those competent to express an opinion, founded on an observed frequency of result, I would then be in hearty agreement with Colonel Woodruff's view that it must in some way be due to too rigid an observance of the old canons of the dietetic treatment of typhoid patients.

If I am right, as I believe I am, in saying that I have not observed tubercle following on typhoid, while other observers note the frequent sequel, the difference must be due in some way to the treatment I adopt. For many years now I have discarded altogether any routine in the dietary of my typhoid patients and have adopted a plan which, summed up in a sentence, is: "Feed a typhoid according to his appetite," controlled *only* by frequent examination of his abdomen and stools, the former giving a very early warning of any tendency to distension, the latter being a measure of the completeness of digestion (all ordinary articles of diet being allowed except fruits with small seeds, grapes being especially forbidden owing to the almost hooklike tip of their pips).

My first published article on the subject appeared in the *British Medical Journal* for 1906, and in that article I pointed out that I had never had any reason to regret my line of practice, and I can say that my experience since has *not* led me in any way to modify my views. There was also another very striking point which I brought out—viz., that having adopted my plan for some years before I published my results, I had practically forgotten that there were such things as complications and sequelæ of typhoid, because I had seen so few examples amongst the 200 or so cases upon which my paper was founded; I had had my proportion of deaths from toxæmia, but my proportion of complications and sequelæ was almost infinitesimal, while I gained nearly a fortnight in the average duration of the stay in hospital. I published a fuller article on the matter in the *American Practitioner* for May and June, 1913.

I am, Sir, yours faithfully,

Harley-street, W., April 20th, 1914. FRED. J. SMITH.

TONSILS AND ADENOIDS IN CHILDREN.

To the Editor of THE LANCET.

SIR,—The plea for fewer operations made by Mr. T. B. Layton in THE LANCET of April 18th is very timely. As a responsible school medical officer I may say I have from the first fostered a conservative attitude on this subject. Undoubtedly the removal of tonsils and adenoids in carefully selected cases is an operation of the highest possible value, and should be urged as a necessity. There are, however, two or three points raised in Mr. Layton's paper, which I propose briefly to comment upon, as my own experience has led me to exercise my judgment.

1. The presence of carious teeth and septic mouths as a cause of glandular enlargement. Not many months ago I was asked to issue a voucher for an operation on the tonsils of a school child who had not been previously medically inspected under the Act of 1907. I was informed that the local doctor had said that removal of tonsils was necessary. As I strongly hold that no vouchers for operation should be issued by an education authority unless the child has been previously medically inspected, I made arrangements to see this child myself when visiting the neighbourhood in connexion with some county work. The tonsils were only moderately enlarged and were, in my opinion, distinctly consequent upon eight carious teeth in the child's jaws. To have removed the tonsils with the mouth in such a condition would, in my opinion, have been bad surgery. I declined to issue a voucher for removal of tonsils, and pointed out that the dental surgeon was the proper person to deal with the case. I shall be disappointed if the tonsils do not undergo

spontaneous cure when once the teeth are properly attended to.

2. The second point is with respect to infection with scarlet fever, &c., as a post-operative complication. With all due respect, I beg to differ from Mr. Layton that the disease is incubating in the child when the operation is done. On the contrary, I am of opinion that the mechanical injury to the tissues inseparable from the operation is an evolutionary factor which enhances the pathogenicity of some almost ubiquitous mouth micro-organism and directly produces a *de novo* case of scarlet fever in a susceptible child.

The evolutionary factor is unquestionable in post-operative pneumonia, as admitted by Mr. Layton, and I am of opinion from cases which have come under my observation that it is equally responsible for some of the cases of post-operative scarlet fever. (We sometimes see a similar sequel after burns.) The practical suggestions made by Mr. Layton as to preliminary use of formalin tablets for a few days before operation, and the adoption of Professor Killian's rule "never to operate if the temperature be above 99° F., deserve wide recognition and adoption.

I am, Sir, yours faithfully,
J. T. C. NASH.
Norwich, April 20th, 1914.

THE RAPID INCREASE OF DIABETES IN WOMAN.

To the Editor of THE LANCET.

SIR,—Until quite recently we were accustomed to look upon diabetes mellitus as a disease which attacked males much more frequently than females, the proportion being, in fact, about 3 to 1. During the last 25 years, however, there has been, at least in this country, an extraordinarily rapid increase of the disease in both sexes, and such a much more marked increase in the case of females than males that the records even of the Registrars-General of England, Scotland, and Ireland respectively would seem to indicate that very soon the frequency of the disease in females will surpass and greatly exceed that in males.

The following returns of death from diabetes specifically as furnished by the three Registrars-General of the United Kingdom, cannot fail to make us apprehensive that some prejudicial change in the mode of living in this country must have taken place during the last quarter of a century which is accountable for the great and rapid increase of the disease.

Deaths Registered from Diabetes in England and Wales.

Year.	Males.	Females.	Total.
1890	1076	787	1863
1900	1455	1312	2767
1911	1936	1917	3853
	In Scotland.		
1890	45	56	101
1900	154	166	320
1911	206	239	445
	In Ireland.		
1890	115	65	180
1900	162	106	268
1911	203	193	396

From the aforesaid returns, moreover, it is impossible for us to form anything like an adequate idea of the alarming increase of diabetes, for it must be remembered that very many more diabetics die every year than the returns of the various Registrars-General disclose. A state of hyperglycæmia lowers the resisting powers of the body and so renders the individual more susceptible to other diseases, to diseases which are apt to prove more fatal than usual because of the excess of sugar in the blood, and under such circumstances the death is registered under the intercurrent and not under the fundamental disease. The existence even of the diabetic state may neither have been known to the patient nor the medical attendant, and it may have escaped detection, for it is well known that during acute febrile diseases in diabetics the sugar often disappears temporarily from the urine.

It is undoubtedly a noteworthy fact that in the case of Scotland the death returns from diabetes are in 1911 quadruple what they were in 1890, and that in Ireland as well as England the specific death-rate from this disease is to-day twice what it was 25 years ago. Confronted with such facts we are impelled to believe that the great and rapid increase of the disease must be due to some influence or influences of a prejudicial character which have become more prevalent during the last quarter of a century. In my opinion the most important retrograde change in our mode of living which is disturbing the metabolic processes in our bodies and rendering us more susceptible to a state of hyperglycæmia is that which concerns our foodstuffs. Twenty-five years ago the question of adding chemical preservatives to our foodstuffs was unthought of, the practice of polishing rice and thus depriving this cereal of some of its most important mineral substances was unknown, and so, too, was the roller process of milling wheat as well as the bleaching of an already too impoverished flour. If the metabolic processes in our bodies are to be maintained *efficiently* the ingested foods will have to be more *wholesome* and less tampered with than they are *to-day*.

I am, Sir, yours faithfully,
JAMES OLIVER, M.D. Edin., F.R.S.E.
Harley-street, W., April 11th, 1914.

ALLEGED MALINGERING UNDER THE INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—The return of many insured patients to work on the appearance in their district of the medical referee has been widely commented upon. It has been hailed as an administrative triumph and as defending the Insurance Act, if not from the fear of its enemies, at least from danger of impending bankruptcy. A sympathising press has spilt much ink and shed virtuous tears over the wickedness of fraudulent patients and conniving doctors, as if further inquiry into the merits of the case were needless, and nothing remained to be attended to but the punishment of the guilty. The surprising thing has been that members of the medical profession should have been ready to join in the general outcry, and this fact it is which, perhaps more than anything else, accounts for the partly perplexed and mainly indignant feeling among panel practitioners.

In order to ascertain what foundation there may be for the allegations that have been made, I have looked up my notes of the few cases of my own in which the question of malingering has been raised, with results which have seemed to me instructive, and am writing this in the hope that others may be led similarly to examine the matter for themselves, and, it may be, to take a more favourable view of the *morale* both of the insured and of the insurance doctors than seems at present to prevail. The cases to which I wish to invite special attention constitute the majority of those patients of mine against whom accusations of fraud have been made or insinuated, and while not concerned to defend all their proceedings or to cast any aspersions on the skill and impartiality of the referee, I am bound to say that they did not at the time, and do not now, appear to me to have been cases of malingering at all. What they were and how far deserving of the treatment they received will be best indicated by three quite recent examples.

First, there is the case of a half-witted girl aged 19, rheumatic and neurasthenic, with a weak heart and frequent localised neuritis, who midway in one of her many illnesses went off the sick list, not because she felt able for work, but because she "was worried by the health visitor," and had before her eyes the fear, to her a very terrible one, of the medical referee. Next is the case of a teacher, aged 34, of extremely poor physique and not over strong mentally, recommended to take a long rest, but advised by the visitor that "although unable to teach she ought to find other work, which she could do," deterred from claiming sickness benefit through fear of being accused of fraud, and in the end throwing herself loyally on the charity of friends in order to obtain the prescribed rest. And, finally, there is the case of a barman, aged 27, with a valvular heart lesion and the peculiar type of combined physical and mental inefficiency which results from what is euphemistically called poor living, but what in his case was, in fact, chronic semi-starvation. The repeated catarrhs with slow recoveries, which form a large part of this man's insurance record, drew the attention of his Approved Society, who sent him a summons to appear before the medical referee. In this instance—and I am sorry to say that it is the only one of the kind I have to record—the zeal of the sham-detectors was unrewarded. In other respects they had planned the affair admirably, but a small oversight spoiled all. They had raided their victim at a time when he was not merely drawing no sick pay, but was actually at work earning his living.

The point in these illustrations, which it is the object of this letter to press home, is that under the Insurance Act we have to do with a very large number of persons who by constitution are, and must always remain, incapable, even under the most favourable conditions, of earning their living steadily and permanently; who, when they fall ill, require long periods of rest in order to recover, but who, as things are at present, have every inducement to resume work before they are in a fit state to do so. We have to ask ourselves whether it is right that such unfortunates should have constantly held over them the dread of being denounced as malingerers. Behind its somewhat cumbrous machinery is there not in this Act a humane intention meriting consideration from those who have to administer it? Is not this intention to lower in some degree the level of tolerable pain? Is it any part of the business of medical men to assist in frightening the "casual," the neurasthenic, the "born tired," and the feeble-minded into performing a little more painful labour than could otherwise be got out of them, for no other purpose than that an Act of Parliament, which is confessedly underfinanced, should go on for a little longer without having its notorious imperfections set right? Such are the questions which recent talk about malingering has set many of us asking, and which, once raised, can hardly be allowed to fall into abeyance till they have reached a final settlement.

In offering the above observations I do not, of course, deny that the class of persons in whose interest they are made furnish their quota of feigned illness. Having less vitality, they necessarily have for the most part less conscience than others, and will lie and prevaricate, when it serves their purpose, without scruple. What I would urge is that the expense entailed by their occasional malingering is a less serious evil than the premature and inconsiderate hustling of them into work which at present finds favour. In dealing with them we have, in fact, as far as possible to guard against both dangers, and the only way to do so effectually is to judge each case on its merits, unbiased by fear of irate Insurance Committees on the one hand or of diminishing panel lists on the other. Better to quit medicine altogether than practise it in the spirit of the slave.

I am, Sir, yours faithfully,

Stoke Newington, April 17th, 1914. I. B. MUIRHEAD.

THE BIOLOGY OF TUMOURS.

To the Editor of THE LANCET.

SIR,—I quite see the point made by Mr. Mansell Moullin in his letter in THE LANCET of April 11th, and must thank him for the explanation. In these laboratories we are trying to get to the bedrock of the questions of growth and reproduction because they seem to be the basis of the cause of tumours, including cancer; therefore I hope that Mr. Mansell Moullin will allow me to go into them a little more explicitly. We are trying to obtain answers to these questions not from any carping point of view, but in order to have a working basis.

What is meant by "growth," and does it clash with the expression "reproduction"? Assuming for the moment that a cell is the unit of life, when the cell divides (reproduction) into two, and the two into four, &c., if we are concerned with reproduction only, each daughter cell would be half the size of the parent, and as the generations pass the cells should progressively get smaller. But this is not the case. Each daughter cell *grows* until it usually attains the size of its parent. It seems to me, therefore, that when we speak of a tissue or an animal growing, we consider a condition brought about by a combination of two factors—reproduction, which increases the numbers, and growth, which increases the size of the individual units.

But this does not explain the meaning of "growth." It would appear that we must go further back than the cell as the unit of life—to the unit of living matter, which possibly is molecular; experiments with aniline dyes show that cells will live and move with part of their protoplasm apparently killed. When a cell grows, how does the increase of size take place? Is it due to each molecular unit increasing in size, or is it due to the reproduction of the units themselves bringing about an increase in their numbers? If the latter, it would seem justifiable to neglect the word growth.

This brings us to the question as to what are the effects of foods, which appear to build up the units and so increase their size. Foods contain auxetics, which stimulate reproduction; but the chemical groupings of auxetics (e.g., guanidine) are not necessarily foods. I fear these questions take us into deep water, but they are important to pathology. I hope that Mr. Mansell Moullin will suggest any line of experiment, and I agree with him that negative evidence, such as that which shows that certain cells will not divide without an auxetic, is difficult to prove outright. But I hesitate to believe that it is impossible, and every effort is being made, and I think should be made, to prove the point one way or the other. It seems improbable that a function like reproduction should have more than one immediate exciting cause.

I am, Sir, yours faithfully,

H. C. ROSS.

The John Howard McFadden Research Fund, London, S.W., April 17th, 1914.

INTERNATIONAL ANATOMICAL TERMINOLOGY: A CORRECTION.

To the Editor of THE LANCET.

SIR,—I should be obliged if you could find space to allow me to rectify an unfortunate *lapsus calami* in the "Plea for an International Anatomical Terminology Based upon the B.N.A.," which appeared in the second column of page 1132 of your issue of April 18th. I quote the offending words in italics. "How many of the 'nervi cerebrales' of the B.N.A. are in any sense cerebral? *These nerves are attached to the brain and spinal cord, and they pass to and fro through foramina on the one hand in the cranium, on the other in the spinal column.*" The error must have crept in at the last moment, for a recent manuscript, the only one on which I can now lay hands, reads: "The nerves attached to the brain and spinal cord pass," and so on. This wording was adopted in order to avoid clashing with either the British nomenclature or the B.N.A., for in the former the "cerebro-spinal" nervous system gives off the "cranial" and the "spinal" nerves, whereas in the latter the "cerebral" and the "spinal" nerves are attached to the "central" nervous system. In truth it is not easy to steer a safe course through these terminologies. They are almost as dangerous as the dark rocks of olden time, between which if a man should venture to sail they would crash together and crush his bark to atoms.—I am, Sir, yours faithfully,

WM. CUTHBERT MORTON.

The University, Leeds, April 18th, 1914.

A GAS INJECTING APPARATUS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 18th there is illustrated under this heading "a new form of apparatus now in use at the Pinewood Sanatorium for injecting nitrogen or oxygen gas into the pleural cavity," and described as a "modification of the Kornmann, simplified."

I should like to warn intending users against the risk to which they will expose their patients. The illustration shows, and the description confirms, that "a large bottle reservoir is placed on a shelf behind, above the level of the top of the gas cylinders, and connected," &c. Measurements show that to displace all the water or fluid by nitrogen or oxygen gas will require a pressure equal to a column of 80 cm. of the fluid used. Thus the gas in the cylinder must be under this pressure, and on turning on the tap to connect with the needle a jet of gas at this pressure is forced through the point of the needle into the cavity or tissues where it may chance to be, and continuing until the pressure equalises, when the bottom tap is turned on and again this pressure is caused, the possible minimum pressure being the height of the gas cylinders, about 60 cm. —a too dangerous and totally unnecessary pressure for any contingency.

By the use of a cylinder of 29 cm. circumference and 36 cm. in depth holding 2000 c.c. attached to the back of a Kornmann apparatus at a level slightly below that of the gas cylinders in front, and connected to them by a three-way tap, I have an apparatus in use here in which it is impossible to produce a pressure greater than that of a column of 30 cm. of fluid, and with the gas cylinders filled to zero registering a pressure of 20 cm., which is more than sufficient for any purpose, and by the use of a small hand bellows attached to the large cylinder the upper portions of the cylinders are easily emptied of gas at any required pressure.

Murphy has laid great stress on the dangers of gas under pressure, and advises that it should be allowed to pass in only under the negative pressure produced in the chest. I have, however, found it necessary in some cases to produce a positive pressure up to 12 cm.; but this is invariably towards the end of the operation, when it would be almost impossible to obtain it with the apparatus shown without refilling, or raising the reservoir as against the simpler use of the hand bellows.

I am, Sir, yours faithfully,

ALFRED ADAMS, M.D.Liverp., D.P.H.

The Sanatorium, Delamere Forest, April 20th, 1914.

THE WATER-SUPPLY OF TUTICORIN.

To the Editor of THE LANCET.

SIR,—The inhabitants of Tuticorin, in any event, owe you a deep debt of gratitude for your able and interesting leading article on "Leisurely Tactics at Tuticorin" that appeared in THE LANCET of Feb. 1st, 1913. We were confident that it would certainly awaken the conscience of the local government and that immediate steps would be taken by the latter to redress the long-felt grievance of the inhabitants of this flourishing seaport. But in this we have been disappointed.

The rapid progress made in that branch of sanitary science which deals with the investigations of the causes of diseases enables us to assert authoritatively that the nature and quality of the water used by any community is a matter of vital importance. Is it to be wondered, then, that this unfortunate city should be visited periodically with cholera and other diseases when no provision has been made to give the people a sufficient supply of good drinking water?

The present water-supply of Tuticorin is tapped from the Tampravarni river, the reservoir being at Korampallam, a village about five miles south-west of Tuticorin. This and the tank half a mile away, which directly feeds the several wells of the town, are open, so that the supply is invariably contaminated, and it is not unusual to find all kinds of animal and vegetable filth washed into them. No attempt at purification has ever been made, and, so far as I know, no serious measures have been adopted to prevent the contamination of the wells from which the people draw their water by means of buckets and other similar appliances.

Tuticorin has been recently favoured with a visit from Lord Pentland, the Governor of Madras, to whom we offered a right loyal welcome. We sincerely hoped that his Government was going to grant us a boon by the gift of a good and unfailing water-supply. But his reply to the address presented by the Tuticorin municipality is very disappointing, and the water scheme that was in progress for more than four years has to be given up on account of increased financial outlay. Money should not stand in the way of carrying out any important sanitary scheme if it is within the range of possibility. Do the authorities who are responsible for this unfortunate state of affairs at Tuticorin realise that every life lost through preventable diseases is money lost to the country and the State?

No one doubts that this town has improved considerably during the past few years except in sanitation. Lord Pentland has told us that within ten years the trade of Tuticorin has increased from 3½ crores to 9 crores. Owing to the importance of Tuticorin as the port of Southern India the opportunities for commercial success are very great, but so long as no effort is made to give this town a good water-supply and thereby render it healthy I have serious doubts whether it will continue to be the centre of British commercial enterprise and the largest port in Southern India after the presidency town, Madras.

With apologies for encroaching on your valuable space,
I am, Sir, yours faithfully,
Tuticorin, March 12th, 1914. F.R.C.S., D.P.H.

⁂ We have had news of a more favourable kind, and we hope that it is true that measures will be taken to provide Tuticorin with an adequate and pure water-supply. It is as necessary that an adequate supply should be secured as that it should be pure. The use of enclosed conduits and the protection of reservoirs are absolutely necessary, but it must be remembered that such precautionary measures will not increase the supply, and that in times of drought the natives are practically without water.—ED. L.

THE NATIONAL INSURANCE ACT.

THE QUESTION OF LIABILITY FOR STATEMENTS MADE IN CERTIFICATES.

IN connexion with an inquiry before a subcommittee in Kent as to allegations made against medical practitioners on the panel, the question has been raised before the Kent Insurance Committee as to the position of medical men who give certificates, and whose certificates are handed to others than the patients concerned. Mr. A. Maude, treating the matter on behalf of the medical profession, expressed the opinion that the certificates could be made the subject of an action for damages for libel, that there was no statutory protection with regard to them, and that a certificate might contain a statement to the effect, for example, that an insured person was suffering from alcoholism or venereal disease, which might be resented by the patient and upon which a claim for damages might be founded. This possibility was recognised in the House of Commons when the Bill was in the Committee stage, and as a way out of the difficulty it was suggested that the certificate might be handed to the patient, who could pass it on to his society or not as he preferred. In reply to this it has been suggested that it is not right in the patient's interest in some cases to inform him fully as to his condition, but that in any case to inform a society of a patient's state behind his back is a breach of faith. The matter is not without doubt and difficulty, because it is clearly undesirable that a member of the medical profession should be made the target of litigation in respect of work done by him professionally and of any statement honestly recorded by him as the result of his professional observation. But if a statement made is found to be true an absolute defence to an action for libel is constituted. Further, if it should be proved that some error had occurred, it would be open to a jury to find that the publication was so made, and the matter published of such a nature, that the occasion was privileged. It seems extremely likely that in most imaginable cases under the Insurance Act a certificate sent to a Friendly Society in order that the Act may be carried out effectively will be found either to be justifiable as true or protected by the circumstances in which it is "published," which it is submitted would include the implied acquiescence of an insured patient in the practice usually pursued in the case of members of his society.

BRISTOL INSURANCE COMMITTEE AND THE UNDISTRIBUTED FUNDS.

At a meeting of the Bristol Insurance Committee the questions raised by Mr. Danckwerts's opinion, taken by the London Insurance Committee as to the allocation of undistributed funds, had as their result the following resolution moved by Mr. J. L. Brown:—

> That in view of the legal opinion obtained by the London Insurance Committee in respect of the unallocated surplus of the Panel Fund, this committee is of opinion that Insurance Committees throughout the country should be permitted to expend such surplus for the benefit of insured persons; they are further of opinion that such sums could be beneficially used in this direction, under Clause 21 of the National Insurance Act, in the provision of trained nurses for the purpose of nursing insured persons in cases of serious illness at their own homes or at suitable institutions, as provided by the Act.

An interesting and prolonged discussion took place in which the various aspects of the question were laid before the committee by the speakers, and an amendment was moved that the matter should be reported on by the Medical Benefit Sub-committee. In support of this it was suggested that if the undistributed funds did not go to the medical men on the panel the claims of the druggists might be considered and a portion of the money available might be used for making up the deficiency in respect of medicines prescribed. The amendment was, however, lost and the resolution carried by a large majority.

THE LIMITATION OF THE PANEL PRACTITIONER'S DUTIES.

An important question seems likely to be submitted for the decision of the Insurance Commissioners by the Surrey Insurance Committee. An insured person consulted a medical man on the panel, who found a papilloma on the lip of the patient, which he successfully excised. He performed the operation when unaware that the patient was insured, and charged a guinea for the operation. The local secretary of the Approved Society to which the patient belonged brought the matter before the Insurance Committee, and on the one side it was contended that the medical man could not make any charge to an insured patient, who was entitled as a right to such services as a medical practitioner on the panel could render, whereas those who differed held that the operation was outside the ordinary services due from a medical man on the panel and supported the unanimous finding of the Local Medical Committee that the operation "was not of a kind which can consistently and in the best interests of the patient be properly undertaken by a general practitioner with ordinary competence and skill." The subcommittee which had inquired into the question had recommended that the Insurance Committee should accept this decision of the Local Medical Committee and should report the matter to the Insurance Commissioners. One of the speakers at the meeting of the Insurance Committee said that from an interview which he had had with the Commissioners at the time of the passing of the Act, and from what he heard the Chancellor of the Exchequer say at a conference of the Advisory Committee, there could be no doubt that the intention was as expressed by the decision of the subcommittee. Eventually it was agreed that the matter should be further considered by the subcommittee, and the ultimate result if it leads to the Commissioners laying down principles upon which their rule is to be interpreted will be of interest.

GLASGOW AND UNDELIVERED MEDICAL CARDS.

At Glasgow the Borough Insurance Committee has had to consider the case of over 40,000 insured persons who have not received their medical cards through the post owing to unnotified changes of address. The Commissioners had suggested removing the names of these persons from the registers, but the chairman at a recent meeting of the committee stated that it had been decided before doing this to take further steps to get the cards into the hands of those for whom they were intended.

Medical News.

UNIVERSITY OF LONDON.—At the Second Examination for Medical Degrees, held recently, the following candidates were successful:—

Part I., Organic and Applied Chemistry.—Gustave Adler, London Hospital; Eric Miles Atkinson, St. Bartholomew's Hospital; Roy Douglas Aylward, London Hospital; Kenneth Norman Grierson Bailey, St. Bartholomew's Hospital; Santiago Ernesto Barraza and John Churchill Blake, University College; Harold John Blampied, St. Thomas's Hospital; Joseph Erwin Adolphe Boucaud, Geoffrey Bourne, and Norman Jesse Boxall, St. Bartholomew's Hospital; Charles Hargreaves Bracewell, University of Liverpool; Reginald Bertram Britton, University of Bristol; Elsie Charlotte Bulley, University of Liverpool: Ellinor Marjorie Burnett, London (Royal Free Hospital) School of Medicine for Women; Francis Caldecott, Guy's Hospital; Thomas Carlyle, St. Bartholomew's Hospital; Duncan Gillard Churcher and *Wilfrid Edward Le Gros Clark, St. Thomas's Hospital; Apollo John Cokkinis, St. Mary's Hospital; Eric Vere Corry, University College; William Adlington Date, St. Mary's Hospital; Charles Owen Davies, University of Liverpool; George Vincent Davies, St. Mary's Hospital; Edwin Frank Deacon, Guy's Hospital; Simon Cyril de Silva Wijeyeratne, University College; Phyllis Decima Dixon, London (Royal Free Hospital) School of Medicine for Women; Howard Lexter Douglas, London Hospital; Monte Edwards, St. Thomas's Hospital; Guy Waterman Elkington, Guy's Hospital; David Washington Evans, University of Bristol; Grace Hamilton Ewart, London (Royal Free Hospital) School of Medicine for Women; William Feldman, University College; Gerald Hartas FitzGerald, Guy's Hospital; *Richard Kenrick Foulkes, King's College; Maximilian Walter Geffen, University College; Nannie Gibson and Dorothy Gilford, London (Royal Free Hospital) School of Medicine for Women; Lawrence Gill, Guy's Hospital; Ernest Howard Glenny, St. Bartholomew's Hospital; Henry Gluckman, London Hospital; Eryl Glynne, London (Royal Free Hospital) School of Medicine for Women; Alice Muriel Griffiths, University College, Cardiff; Herbert Glynn Hall, University College; Joan Hardy, London (Royal Free Hospital) School of Medicine for Women; Leslie William Hefferman, Middlesex Hospital; Kenneth Reed Hill, University College; Bertha Hinde, London (Royal Free Hospital) School of Medicine for Women; Eric Clark Hinde, Guy's Hospital; Edward Arthur Holmes, King's College; Joseph Christopher Campbell Howe, Guy's Hospital; George Franklin Wise Howorth, Middlesex Hospital; Amy Margaret Kerr, London (Royal Free Hospital) School of Medicine for Women; John Isaac Kühne, King's College; Felix Raoul Leblanc, Guy's Hospital; Emily Catherine Lewis, London (Royal Free Hospital) School of Medicine for Women; Gordon Parmiter Lindsay, Guy's Hospital; Alice Lloyd Lloyd-Williams, London (Royal Free Hospital) School of Medicine for Women; Kenneth McFadyean, University College; Robin Gordon Mack, St. Bartholomew's Hospital; Bruce Maclean, University College; Gladys Matthews, London (Royal Free Hospital) School of Medicine for Women; Puthiyaveettil Narayana Menon, University College; Farid Morcos, St. Mary's Hospital; Ernest Rudolf Dudley Nagel, St. Thomas's Hospital; Martin Herbert Oldershaw, University College; Alexander Edward Patrick Parker and Frank Portas, King's College; Eric Denholm Pridie, University of Liverpool; Henry Norman Pritchett, Guy's Hospital; Olive Rendel, London (Royal Free Hospital) School of Medicine for Women; John Charles Ryder Richardson, London Hospital; Gabriel Francis Rodrigues, University College; James Paterson Ross, St. Bartholomew's Hospital; Eleanor May Scarborough, London (Royal Free Hospital) School of Medicine for Women; William Keith John Scroggie, University College; *Simeon Cyril Shaw, Middlesex Hospital; Reginald Henry Sunderland, London Hospital; Noel Tayler, University College; Montague Beavan Tench, Middlesex Hospital; Benjamin Thomas, St. Mary's Hospital; *Daniel Jenkin Thomas and John Herbert Thomas, University College; George Edwin Tilsley, University of Bristol; Charles Maitland Titterton, St. Bartholomew's Hospital; Alfred Robert Tothill, King's College; Kenneth Robert Traill, Guy's Hospital; Kenneth Tratman King Wallington, University College; Richard Walters, London Hospital; Sydney Arthur Thomas Ware, St. Thomas's Hospital; Frederick William Arbuthnot Watt, London Hospital; Gladys Millicent Rutland Webster, London (Royal Free Hospital) School of Medicine for Women; Alfred Douglas Weeden, Middlesex Hospital; Sik To Wong, Guy's Hospital; Sydney Carver Woodhouse, London Hospital; Irene Yates, London (Royal Free Hospital) School of Medicine for Women; and Frank Young, Guy's Hospital.

* Awarded a mark of distinction.

The following advanced free lectures in physiology will be delivered during the third term of the session 1913-14: 1. A course of eight lectures on Oxidation in the Tissues, at University College, by Mr. C. Lovatt Evans, D.Sc., at 4 P.M., on Fridays, May 8th, 15th, 22nd, 29th, and June 5th, 12th, 19th, and 26th. Attendance at this course is recognised in connexion with the B.Sc. (Honours) degree in Physiology. 2. A course of four lectures on the Regulation of the Composition and Volume of the Blood, in the physiological laboratory of Guy's Hospital, by Dr. J. S. Haldane, F.R.S., at 4 P.M., on Thursdays, May 7th, 14th, 21st, and 28th. 3. A course of four lectures on the Gaseous Exchanges of the Body, in the physiological laboratory of King's College, by Dr. T. G. Brodie, F.R.S., professor of physiology in the University of Toronto, at 4.30 P.M., on Monday, June 8th, Wednesday, June 10th, Monday, June 15th, and Wednesday, June 17th.—The following lectures in advanced medical subjects will also be delivered free during the third term: (1) A course of three lectures on Carbohydrate Metabolism in Health and in Diabetes, by Dr. Hugh MacLean, at St. Thomas's Hospital Medical School, at 5 P.M., on Tuesdays, May 5th, 12th, and 19th; and (2) one lecture on Recent Observations upon Ulcer of the Stomach, by Dr. Charles Bolton, at University College Hospital Medical School, at 5 P.M., on Friday, May 22nd.—The Semon lecture in Laryngology, 1914, will be delivered by Professor Gustav Killian, of the University of Berlin, at the Royal Society of Medicine, Wimpole-street, on Thursday, May 28th, at 5 P.M., the subject being Suspension Laryngoscopy and its Practical Use. The chair will be taken by Sir Felix Semon, K.C.V.O. Admission free, by ticket obtainable from the Academic Registrar, University of London. —In the physiological laboratory at South Kensington a course of eight lectures on the Rate of the Blood-flow in Man in Health and Disease will be given by Dr. G. N. Stewart, professor of experimental medicine, Western Reserve University, Cleveland, U.S.A., at 5 P.M., on Tuesdays, May 5th, 12th, 19th, and 26th, and June 2nd, 9th, 16th, and 23rd.—Dr. Arthur Cyril Hudson has been recognised as a teacher of the University (Ophthalmology) at the Royal London Ophthalmic Hospital.—A University studentship in physiology, of the value of £50 for one year, will be awarded to a matriculated or graduated student of the University qualified to undertake research in physiology, and will be tenable in a physiological laboratory of the University or of a school of the University. Applications much be received by the Principal on or before May 31st.—The National Dental Hospital and College has been admitted as a school of the University in the Faculty of Medicine (in dentistry only) until Sept. 30th, 1916.

SOCIETY OF APOTHECARIES OF LONDON.—At the Primary Examination held on April 6th, 8th, and 9th the following candidates passed in the subjects indicated:—

Biology.—A. S. Newton, Liverpool.
Chemistry.—A. S. Newton, Liverpool.
Materia Medica and Pharmacy.—G. H. C. Harding, Liverpool;

A. E. Pollitt, Manchester; F. Simpson, Charing Cross Hospital; and F. Smith, Manchester.
Anatomy.—E. V. Briscoe, St. Mary's Hospital; D. V. Halstead, Guy's Hospital; P. Hughes and T. F. Reason, St. Mary's Hospital; R. D. M. Tims, St. Thomas's Hospital; and C. G. G. Winter, St. Mary's Hospital.
Physiology.—E. V. Briscoe, St. Mary's Hospital; D. V. Halstead, Guy's Hospital; D. E. Hearn, Durham; P. Hughes and H. D. L. Jones, St. Mary's Hospital; W. J. Walters, Cambridge and Guy's Hospital; and C. G. G. Winter, St. Mary's Hospital.

QUEEN'S UNIVERSITY OF BELFAST.—At examinations held recently the following candidates were successful:—

SECOND MEDICAL EXAMINATION.

Anatomy and Physiology.—Mary I. Adams, George V. Allen, Charles D. Crawford, Francis Ewart, Eli Freeman, James A. Harbison, John M. M'Cormack, Thomas J. Marner, William Napier, William H. Pedlow, John Scott, Ernest S. G. K. Vance, Robert Weaver, and John Wilson.
Physiology.—Hugh B. Hall and Arthur J. Millar.

THIRD MEDICAL EXAMINATION.

Pathology, Medical Jurisprudence, and Hygiene.—Robert M. Beath and Sinclair Miller.
Pathology and Materia Medica.—Albert E. M. Carleton, John Cullenan, Charles F. Davey, James E. Finlay, Patrick Kane, James M'Kay, Joseph B. M. Mackenzie, Sylvia Marsh, John F. Meenan, William N. Montgomery, William Russell, Herbert S. Smith, and James M. Smith.
Medical Jurisprudence and Hygiene.—Eileen M. Bell, David Corry, and Michael Gilligan.
Materia Medica.—Ribton G. Blair.
Pathology.—William C. M'Cullough.

APOTHECARIES' HALL OF IRELAND.—The following candidate having passed the necessary examination has been admitted a licentiate:—

Richard John Aherne, L.R.C.P. & S. Irel.

A DEVONSHIRE CENTENARIAN.—Mr. Jonathan Lock died at Plymouth on March 31st in his 102nd year.

SCHOOL MEDICAL SERVICE GROUP OF THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Medical officers whose duties include school medical work and who reside in the metropolitan and home counties areas are invited to attend a meeting, on Saturday, May 2nd, at 2 P.M., of the School Medical Service Group of the Society of Medical Officers of Health at 1, Upper Montague-street, Russell-square, London, W.C., for the purpose of forming sub-groups for these respective areas. The general meeting of the group will be held at 3.30 P.M. at the same address, and all officers having any school duties are entitled to join the group and attend its meetings. Matters affecting the future status of the service, especially of the assistant officers, will be discussed at these meetings. The honorary secretary of the group is Dr. Armly Ashkenny, 38, George-road, Edgbaston, Birmingham.

DONATIONS AND BEQUESTS.—By will the late Mr. Septimus Brocklehurst, of Sefton Park, Liverpool, left £1000 each to the Liverpool Convalescent Institution, Woolton; the Royal Liverpool Country Hospital for Children; the Children's Convalescent Home, West Kirby; and the St. Paul's Eye Hospital, Liverpool.—Among other charitable bequests the late Mr. Benjamin E. Mocatta has left £500 to University College Hospital.—By the will of the late Mr. T. Sherran Whittaker, whose net personalty has been sworn at £15,000, one-half of the residue, after certain bequests have been made, will go to Guy's Hospital and the other half will be used for the purpose of founding and endowing a cottage hospital for poor persons resident in Broadstairs or the Isle of Thanet. —The late Alderman Henry Harrison, besides numerous other bequests, by his will bequeathed the following charitable legacies free of duty: the Blackburn and East Lancashire Infirmary, £1000; the Seamen's Hospital Society, £3000; the Imperial Cancer Research Fund, £1000; the Cancer Investigation Department of the Middlesex Hospital, £1000; and the Cancer Hospital (Free) for Cancer Investigation, £1000. —The late Mrs. Mary Mitchel, of Baggrow, Allhallows, Cumberland, has left by will £1000 each to the Blencathra Sanatorium, Threlkeld, the Cumberland Infirmary, and the Cumberland and Westmorland Convalescent Institution at Silloth.—His Majesty's First Commissioner of Works has sent a donation of £1000 to St. Thomas's Hospital to endow a bed for the use of Civil servants. The bed will be known as the King George V. Coronation Bed.—An anonymous donor has sent a cheque for £500 to the Huddersfield Royal Infirmary for the endowment of a cot in perpetuity in the children's ward.—The late Mr. John Ritchie, of Liverpool, has bequeathed £250 each to the Royal Infirmary, Liverpool, the Royal Southern Hospital, Liverpool, the David Lewis Northern Hospital, Liverpool, the Infirmary for Children, Liverpool, and the Bootle Borough Hospital.

THE Reverend Walter John Barton has been appointed to the head mastership of Epsom College, which will become vacant at the end of the summer term, owing to the resignation of the Reverend T. N. H. Smith-Pearse, who has held the office for 25 years. At Oxford Mr. Barton obtained a first class both in Moderations and in Literæ Humaniores. For the past seven years he has been an assistant master in classics at Winchester College, and is also a distinguished geographer.

SEVENTH ANNUAL NURSING AND MIDWIFERY CONFERENCE.—This conference will be held at the hall of the Westminster Yeomanry, adjoining the Horticultural Hall, Westminster, S.W., from Tuesday, April 28th, to Friday, May 1st, both dates inclusive. The proceedings will begin each day at 2.30 P.M. At the afternoon session on April 28th the State registration of nurses will be discussed by Sir Victor Horsley, and the proposed London County Council registration of nursing homes will be dealt with by Miss L. M. Stower. In the evening, under the chairmanship of Colonel Bruce Skinner, M.V.O., the work of the St. John Ambulance Brigade will form the subject of a paper by Lady Perrott, Mr. James Cantlie will describe the work of the Red Cross Society, and Miss Hilda Stewart will criticise from the trained nurses' point of view the work of Voluntary Aid Detachments. At 8.30 P.M. there will be a reception by the committee at the Rooms of the Royal Society of Medicine, after which an address will be delivered by Sir George Savage. On April 29th Dr. Elizabeth Sloan Chesser will preside, and Dr. Burnett Ham, late chief medical officer for Victoria, and Dr. Lucy Naish will respectively deal with the eugenic consideration of venereal diseases and the infant's first week of life. Among other subjects to be dealt with will be the development of infant consultations and the moral influence of the midwife. On April 30th Dr. T. N. Kelynack will occupy the chair, tuberculosis being the subject for discussion. Dr. H. Hyslop Thomson will speak on the care and control of the tuberculous patient. In the evening Dr. Janet Lane-Claypon will preside, and Dr. Annie McCall will take for her subject how to avoid operative midwifery, the effect of the Insurance Act upon lying-in hospitals being dealt with by Mrs. Glanville. At a later session on the same day Dr. J. S. Fairbairn will speak on the teaching of midwifery by lantern slides. On the last day of the conference, May 1st, under the chairmanship of Dr. R. Murray Leslie, Dr. Robert Armstrong-Jones will deal with the progress of mental nursing, Dr. Edwin L. Ash will take for his subject the nurse and the care of nervous patients, and Dr. R. Langdon Down the Mental Deficiency Act. In the evening, under the chairmanship of Dr. E. W. Goodall, fever will be the subject for discussion, asepsis in fever nursing being dealt with by Dr. A. Knyvett Gordon.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Dogs Protection Bill.

A LETTER of protest has been addressed to the Home Secretary with regard to the Dogs Protection Bill which is now before Parliament. The letter is in the following terms:—

> "We desire to express to you our strong conviction that the Dogs Protection Bill, which is put down for second reading on Friday, 17th inst., would inflict very severe injury, not only on medicine and surgery, but also on the study of the diseases of animals. We think that we have some right to ask you to oppose this attack on the advancement of medical science and practice: especially as the Final Report of the Royal Commission on Vivisection does not advise the prohibition of experiments on dogs. We are absolutely certain that such experiments are necessary for the complete study of many problems of physiology, pharmacology, and pathology."

The above protest, which is signed by more than 350 persons, has been presented by Sir Thomas Barlow, President of the Royal College of Physicians of London, to the Home Secretary. The letter is influentially signed by representatives of the various departments of medical science throughout the United Kingdom. The signatories include the following:—

Medicine.—The President of the Royal College of Physicians of London, Sir Lauder Brunton, Sir James Reid, Sir William Church, Sir James Goodhart, Sir Thomas Fraser, Sir Dyce Duckworth, Sir William Osler, Sir David Ferrier, Sir James Kingston Fowler, Sir Malcolm Morris, Dr. C. E. Fitzgerald (President of the Royal College of Physicians, Ireland), Dr. J. J. Graham Brown (President of the Royal College of Physicians, Edinburgh), Sir Thomas Oliver, Sir Robert Phillip, Sir StClair Thomson, Dr. W. P. Herringham (Vice-Chancellor of the University of London), Professor William Russell (Edinburgh), Dr. Sidney Martin, Dr. James Mackenzie, Sir Alexander Simpson, Dr. W. Hale White, Dr. Byrom Bramwell, Dr. Hector Mackenzie, Dr. Frederick Taylor, Dr. John Playfair, Dr. Nathan Raw, Professor Robert Saundby, Dr. J. Mitchell Bruce, Professor Harvey Littlejohn; the Professor of Medical Jurisprudence, Glasgow; the Professor of Public Health, Edinburgh; and Professor George Murray.

Surgery.—The President of the Royal College of Surgeons of England, Sir Henry Morris, Sir Frederick Treves, Sir W. Watson Cheyne, Sir Frederic Eve, Sir John Bland-Sutton, Sir Berkeley Moynihan, Sir Victor Horsley, Sir Alfred Pearce Gould, Sir W. Arbuthnot Lane, Sir Alfred Fripp; the Professor of Surgery, Edinburgh; Professor Howard Marsh, Cambridge; Mrs. Scharlieb, Professor Gilbert Barling (Vice-Chancellor of the University of Birmingham), Mr. Edmund Owen, Professor William Thorburn, Mr. C. A. Ballance, Mr. Charters Symonds, and Sir George Beatson.

Gynæcology.—Sir Francis Champneys (President of the Royal Society of Medicine), Dr. Berry Hart (Edinburgh), Professor J. M. Kerr (Glasgow), Dr. W. S. A. Griffith, Dr. John Phillips, and Dr. Herbert Spencer.

Hospital administration.—Lord Knutsford (chairman of the London Hospital), Lord Northbrook (president of the Cancer Hospital), Sir Joseph Fayrer (superintendent, Edinburgh Royal Infirmary), Sir Frederick Macmillan (chairman, Queen-square Hospital), Mr. J. T. Helby (chairman, Metropolitan Asylums Board), and Dr. E. W. Goodall (medical superintendent, Eastern Hospital).

Tropical diseases.—Sir William Leishman, R.A.M.C., Sir Ronald Ross, Dr. C. J. Martin (director of the Lister Institute), and Major Cummins, R.A.M.C.

Physiology.—Professor J. N. Langley (Cambridge), Professor C. S. Sherrington (Oxford), Dr. A. D. Waller (London), Professor T. H. Milroy (Queen's College, Belfast), Professor D. Noel Paton (Glasgow), Professor W. D. Halliburton (King's College), Sir Edward Schäfer (Edinburgh), Dr. W. H. Gaskell (Cambridge), Professor W. M. Bayliss (University College), Professor William Thompson (Trinity College, Dublin), Dr. J. S. Haldane (Oxford), Dr. Leonard Hill (London Hospital), Dr. L. E. Shore (Cambridge), Professor Wace Carlier (Birmingham), and Dr. W. Ramsden (Oxford).

Pathology and bacteriology.—Professor Sims Woodhead (Cambridge), Dr. John Eyre (Guy's Hospital), Professor William Bulloch (London Hospital), Dr. R. M. Buchanan (bacteriologist to the Glasgow Corporation), Dr. Carnegie Dickson (Edinburgh), Professor H. J. Hutchens (Newcastle), Professor James Ritchie (Edinburgh), Dr. F. W. Mott (London County Council), Sir Almroth Wright (St. Mary's Hospital), Professor J. Lorrain Smith (Edinburgh), Dr. Vaughan Harley (University College), Professor Walker Hall (Bristol), Dr. Harold Spitta (St. George's Hospital), Dr. J. E. Arkwright (Lister Institute), Dr. J. D. Ledingham (Lister Institute), Dr. F. H. Thiele (University College Hospital), Mr. Alexander Foulerton (Middlesex Hospital), Dr. Ainley Walker (Oxford), Dr. Wakelin Barratt, Dr. Herbert Durham, and Professor W. S. Greenfield (Edinburgh).

Cancer research.—Dr. E. F. Bashford (director of Imperial Cancer Research), Dr. W. S. Lazarus-Barlow (director of Cancer Research, Middlesex Hospital), and Dr. Archibald Leitch (pathologist, Cancer Hospital, Brompton).

Anæsthetics.—Sir Frederic Hewitt (anæsthetist to the King), Mr. A. G. Vernon-Harcourt, and Dr. Dudley Buxton.

Diseases of the nervous system.—Dr. Henry Head, Sir Thomas Clouston, Dr. Edwin Goodall, Dr. George M. Robertson, Sir James Crichton-Browne, Sir George Savage, and Dr. J. S. Risien Russell.

Pharmacology.—Professor Arthur R. Cushny (University College), and Professor W. E. Dixon (King's College).

Veterinary medicine.—Sir John MacFadyean (principal, Royal Veterinary College), and Mr. O. C. Bradley (director, Veterinary College, Edinburgh).

Other sciences.—Sir E. Ray Lankester, Sir Norman Lockyer, Sir William Ramsay, Sir Henry Roscoe, Dr. Raphael Meldola, Professor Edward B. Poulton, Dr. W. H. Perkin, Dr. Charles S. Myers, Professor Alexander MacAlister, and Professor Arthur Keith.

HOUSE OF COMMONS.

THURSDAY, APRIL 16TH.

Treatment of Sick Poor.

Mr. ASTOR asked the President of the Local Government Board what was the total cost of institutional treatment of the sick poor for the last three years for which figures were available.—Mr. HERBERT SAMUEL wrote in reply: It is impossible to distinguish the cost of the treatment of sickness from the other expenses of maintenance of institutions. The Royal Commission on the Poor-laws and Relief of Distress estimated "that at least one-half of the total cost of pauperism is swallowed up in direct dealing with sickness." One-half of the total cost of the relief of the poor in the years ended March, 1911, 1912, and 1913, was approximately £7,500,000, £7,230,000, and £7,460,000.

Mr. ASTOR asked the right honourable gentleman how many boards of guardians had less than 100 beds for the treatment of the sick poor in their own workhouses and infirmaries respectively; how many had between 100 and 200 beds, how many between 200 and 300, and how many over 300 beds.—Mr. HERBERT SAMUEL (by written answer) replied: The following is the number of boards of guardians who have provided beds for the treatment of the sick poor:—

—	Less than 100 beds.	100–200 beds.	200–300 beds.	Over 300 beds.
Workhouses ...	330	36	16	13
Infirmaries	144	41	27	59

The above table includes the provision for chronic cases and cases under medical care but not needing active or continuous treatment or special nursing as well as acute cases. It does not include the number of beds provided by the Metropolitan Asylums Board or by other joint Poor-law authorities.

Mr. ASTOR also asked the right honourable gentleman how many boards of guardians had appointed salaried nurses for attending outdoor sick, how many subscribed to local nursing associations for such attendance, and how many made no provision for nursing the outdoor sick poor.—Mr. HERBERT SAMUEL replied: In eight unions the guardians employ salaried nurses appointed by themselves to attend the outdoor sick; 473 boards of guardians have been authorised by the Local Government Board to subscribe to district nursing associations. In the remaining 165 unions no similar provision has, so far as I am aware, been made, but I may point out that in these unions both the board of guardians and the relieving officers have power to employ a nurse to attend any particular case when required.

District Medical Officers.

Answering Mr. ASTOR, Mr. HERBERT SAMUEL wrote: The total number of district medical officers in England and Wales last year was 3761. In all but six cases the remuneration is by fixed salary with additional fees for midwifery cases and operations. In two unions payment is made wholly and in two partly by fees for attendance. Population has not been adopted as a direct basis for remuneration in any case.

Housing in Dublin.

In the course of the discussion in Committee of Supply on the vote for the Local Government Board, Ireland, attention was called at length to the report of the Departmental Committee on Housing in Dublin.

Mr. CLANCY said that there were still 20,108 families living in one-room tenements in Dublin. The report of the Departmental Committee showed that human beings ought not to be allowed to live in these tenements if they could possibly be accommodated elsewhere. Tuberculosis was bred in these places to an extent which was quite remarkable.

Sir A. GRIFFITH-BOSCAWEN dealt at length with various matters referred to in the report, and asked what steps the Government contemplated taking to remedy the disgraceful state of things which the report revealed.

Lord ROBERT CECIL described the state of things revealed by the report as incredible.

Mr. BIRRELL (Chief Secretary to the Lord Lieutenant of Ireland) said that the responsibility of the Irish Local Government Board for the corporation of Dublin was small. He could not act with any degree of authority except on complaint, and the complaints which had been made from time to time as regarded the Dublin corporation had not been great or numerous and the powers which he had been able to exercise were very small. He was glad that this departmental report of the Local Government Board had excited attention. It was a very painful report. It had put the state of life of the poorer portion of the inhabitants of Dublin in a manner which he did not think anyone could read without feeling grieved and to some extent ashamed. At the same time he did think that the Dublin corporation had been rather harshly dealt with by honourable Members opposite. It had done an enormous amount of work in main drainage, electric lighting, and paving, to say nothing of its own schemes for housing the poor, in which it was acknowledged to have done more than any other municipality in any other city in the United Kingdom. But Dublin was a very poor place. Wages were lamentably low. The rates were close upon 11s. in the £, collected from poor people. That, however, did not alter the fact that this report proved a lamentable state of things, and it had also shown that the Dublin corporation had not exerted to the full, or to the extent which it ought to have done, the legislative powers which it already possessed. An honourable Member had referred to 17 persons in the corporation who were owners of property. There were really only five who owned more than one house, and of the balance of 12, each was the owner only of one single tenement. He did not say that that was right or wrong, but to describe them as being 17 owners of tenement property would rather lead one to infer that they owned a considerable portion, at all events, of the tenement houses in Dublin. They owned a most insignificant fraction of these houses.

and there were not more than two or three who owned more than one or two at the most. He was asked what was he going to do. Something must be done. If more could be done than was done at present to assist Dublin in consequence of its exceptional conditions and the sorrow of its inhabitants, certainly the Chief Secretary would not be indifferent to any proposal of that sort which was likely to be made. But he was sure that no Chancellor of the Exchequer would be satisfied or willing to make a grant to Ireland and to refuse it to other places. It would be a very dangerous proposition to start with that wages were to be kept down by keeping down rents by means of payments which were to come out of other people's pockets. Therefore he could do no more than say that this report did not contemplate an instantaneous remedy of that great wrong. It might be that this corporation had acted selfishly, but at all events it did not create the situation. If it had acted strictly and rigorously up to its duties it was a question whether the members would have succeeded in being returned a second time. Still they might have done more than they had done. When all was said and done, the task of finding proper accommodation for all the poor people in Dublin was a difficult one. It might be said, "Build homes outside," but it would be a difficult thing to persuade them to go. To make a town plan for Dublin successfully and wisely was a task which of necessity must take some little time. On one thing he was perfectly clear, and that was that this report could not be allowed to rest as so many other reports had done in the pigeon-holes of offices. He was glad that this debate should have taken place and that the horrible state of things, in no sense exaggerated, should have been discussed. He hoped that the criticism to which the corporation of Dublin might be properly and fairly exposed, would not do it anything but good, and that honourable Members might look forward in the near future to such a rebuilding and reconstitution of these old tenement houses as must greatly advantage the health, happiness, and morals of the people of Dublin. The tenement houses were, he thought, quite capable of economic improvement if there was a good deal of expenditure upon them. But they must be emptied out of their present inhabitants. The other houses referred to in the report—some of them new and recently built houses—had become just as unfit as, and perhaps in some respects even more repulsive than, the tenement houses themselves. All these things he hoped would sink into the hearts of the people and lead to a remedy.

FRIDAY, APRIL 17TH.

Dogs Bill.

Sir **FREDERICK BANBURY** moved the second reading of the Dogs Bill. He said that he had heard the Bill described as an Antivivisection Bill, and it had been said that it was a measure which stopped vivisection. It did nothing of the kind. All that it did was to stop eminent scientists who did perform operations on living animals from using dogs for that purpose. The return for 1912 showed that the dogs and cats experimented upon without anæsthetics numbered 321. The dogs and cats allowed to recover after serious operations numbered 557. There was a certain amount of evidence given by medical men and learned professors to the Royal Commission on Vivisection to show that dogs were necessary for their experiment. On the other hand, there was also evidence given by other medical men and scientific men to the effect that dogs were not necessary. In the report there was no finding by the Commissioners as to there being a necessity for experiments to be made on dogs. If the Commissioners had been of opinion that in the interests of science it was necessary to include dogs among the animals to be operated upon, they would have said so in their report. The honourable Member read extracts dealing with experiments upon dogs. Man having made a friend of the dog for many thousands of years had rendered that animal particularly sensitive to all forms of pain and terror—much more so than the ordinary animal, which was in a more or less wild state. Therefore, unless it was proved that experiments on dogs were useful to man—and he said that it had not been proved—was it not right that he should ask that dogs should be exempted from being put to the torture of these experiments? He trusted the House would give the Bill a second reading.

Colonel **LOCKWOOD** seconded the motion.

Mr. **RAWLINSON** moved as an amendment the rejection of the Bill. He pointed out that experiments on living animals in this country could only be carried out by persons to whom licences had been granted, and these licences could only be obtained by persons who had received recommendations from the heads of certain scientific institutions. The licence could only be used upon certain registered premises. There was a power given to the Home Office to demand a full report as to what had occurred at a particular operation from the person who was authorised to perform it. That showed that the power of vivisection was restricted in England by the most careful safeguards practically at every operation. If there was any further safeguard required by all means let that matter be considered. Certainly it was not necessary to pass the second reading of this Bill at all to remedy that defect if it existed. This country had already gone further than any other in the way of restricting scientific research. Scientific men said that it was necessary that dogs should be used for experiments. It was owing to the experiments of Pasteur on animals, including dogs, that the nature of hydrophobia was cleared up. Were honourable Members going to hamper for all time the hands of those who were engaged in combating such diseases as cancer by extraordinary restrictions on experiments which might at any moment afford the chance of putting an end to so much human misery, pain, and loss of life.

Sir **PHILIP MAGNUS**, in seconding the amendment, observed that the House could trust scientific men to secure the exclusion and exemption of dogs from all experiments where they were certain that they could find other animals to serve their purpose.

Sir **HENRY CRAIK** opposed the Bill. He said that he wondered how without the inoculation experiments which had been tried upon dogs it would have been possible to attain to the great knowledge now available in regard to tropical diseases. He wondered how the experiments upon the heart which were published the other day would have been possible but for dogs—those experiments which, in the words of a medical man, had revolutionised medical knowledge of the heart and of the way in which medical men could deal with the valves of the heart and with diseases hitherto believed to be incurable. The truth was because of its nervous and physical structure, its habits of life, and the fact that it was at once vegetable eating and carnivorous, the physiology of dogs was more analogous to that of humanity than that of any other animals except the superior ape.

Dr. **CHAPPLE** dealt at length with the valuable scientific results which had been obtained from experiments on dogs. A Bill like the present, with its spurious sentimentality and ignorance of facts, might well interfere with a line of research which promised so much benefit to humanity.

Mr. **ELLIS GRIFFITH** (Under Secretary of State for the Home Department) in speaking for the Government observed that he might be allowed to say a word or two about the present position of affairs and the existing law. In the course of the discussion some charges had been made that there was cruelty, and perhaps unnecessary cruelty, now going on. So far as the Home Office was concerned he desired to say most emphatically that it did not think there was any basis or foundation for that charge. Perhaps the House would allow him to state shortly what were the present safeguards under which these experiments were conducted. In the first place, without anæsthetics there could not be inoculations beyond simple ones or superficial vivisection. In that there was no cruelty. With regard to experiments with anæsthetics these could only take place under three conditions, which were always attached to every licence for any experiment under anæsthetics. First of all, all operative procedures in connexion with the experiments detailed in certificate "B" should be carried out under anæsthetics of sufficient power to prevent the animal from feeling pain. Secondly, the animals experimented on should be treated with strict antiseptic precautions, or if these failed and pain resulted the animals should be immediately killed under anæsthetics. There was a third provision to which he attached special importance. It was in three paragraphs and referred to the anæsthetic condition, the antiseptic condition, and the pain condition. The paragraphs provided first if the animal after and by reason of any of the experiments under certificate "B" was found to be suffering pain which was severe or was likely to endure, and if the main result of the experiments had been attained, the animal should forthwith be painlessly killed. This condition was formerly imposed in some cases. It was now imposed in all cases. The second paragraph provided that if an animal after and by reason of the said experiment was found to be suffering severe pain which was likely to endure, such animal should forthwith be painlessly killed whether the main result of the experiment had been attained or not. That was new and was now universally imposed. The third paragraph provided that if any animal appeared to an inspector to be suffering considerable pain and if the inspector directed such animal to be destroyed it should forthwith be painlessly killed.

Colonel **LOCKWOOD**: That was one of the recommendations of the Royal Commission.

Mr. **ELLIS GRIFFITH**: That is carrying out the recommendation of the Royal Commission, of which the right honourable gentleman was a member. The debate was different from any other debate that had taken place on the subject matter of this Bill. In 1912 the honourable baronet introduced a Bill on the very same day, curiously enough, that the report of the Royal Commission was issued. In 1913 a Bill on this subject passed second reading in a manner best known to the honourable baronet himself without debate. He mentioned this to make it perfectly clear that this was the first time this House had discussed the subject matter of this Bill with the recommendations of the Royal Commission before it. Several extracts had been read from the report that afternoon, but with the exception of three lines no honourable Member had quoted the really operative clause of it. One honourable member quoted the first three lines. They were these: "In view of the variety of practice and divergence of opinion as to the necessity of employing dogs for experimentations and demonstrations, we find some difficulty in deciding upon this important question." There the honourable Member left the matter. Obviously honourable gentlemen must read further. The report proceeded: "Some of us regard the provisions of the existing law as sufficient; some of us would prefer that in the case both of experimentation and demonstration the further special protection given to horses, asses, and mules should be extended to dogs, while some of us would exclude dogs altogether." Now the operative words came: "But if any alteration is made in the existing procedure the majority of us would agree that the special enactments now applicable to horses, asses, and mules might be extended to dogs and also to cats and anthropoid apes." That was really all that the Royal Commission had done upon this interesting point. At present experiments on dogs might be performed as long as the experiments were under anæsthetics without a certificate to the effect that the experiments would be frustrated if a dog was not available, whereas if the experiment was on horses, mules, or asses such a certificate was necessary, and he in the committee last year supported the proposal to make an amendment to the effect that dogs should be put in the same position as horses, asses, and mules so that a special certificate should be required when the experiments were under anæsthetics that no other animal would serve for the particular purpose for which the experiment was made. That amendment was carried, and it led ultimately to the defeat of the Bill. As far as he was concerned what he favoured was not the total prohibition of all experiments on dogs, but if it was thought, as he thought, that additional safeguards were necessary, the safeguards which he had now indicated, should be available for the protection of dogs, so that in future if the suggestion which he had made was accepted no one would be able to have an experiment upon dogs unless it were found that no other animal was available for the purpose. That was a compromise. He did not want to oppose the second reading, but he wished to say quite frankly that he did his best to hold the balance between the two sides in committee last year. If the second reading were passed, he should be under the necessity in committee of supporting or moving some amendment so as not altogether to prohibit vivisection upon dogs, but to give that additional safeguard that belonged to the animals mentioned in Section 5 of the Act of 1876. It was his proposal to remove the dog from one classification to another, and although perhaps it would not satisfy the promoters of the Bill, it would give some safeguard.

The amendment for the rejection of the Bill was defeated by 112 votes to 80. The second reading was then agreed to.

MONDAY, APRIL 20TH.

Ireland and Medical Benefits.

Mr. ARTHUR HENDERSON asked the Chancellor of the Exchequer whether he intended to make an attempt this session to secure the passage of the Bill to extend medical benefits under the National Insurance Act to insured persons in Ireland.—Mr. WEDGWOOD BENN (on behalf of Mr. LLOYD GEORGE) replied: My right honourable friend is communicating with my honourable friend on the matter to the effect that he fears it is impossible to make the promise asked for.

Insured Persons and Medical Tickets.

Mr. CHARLES BATHURST asked the honourable Member for St. George's-in-the-East, as representing the Insurance Commissioners, (1) whether he was aware that Approved Societies were instructed to cease notifying the Insurance Committees of the changes of addresses of their members as from Jan. 12th, whereas the London Insurance Committee failed to send out medical tickets to insured persons resident in their area until the end of March, and that over 25 per cent. of the medical tickets sent out by that Committee had already been returned through the dead letter office; and would he say what steps he proposed to take to secure that the medical tickets should reach insured persons in London who had not received the same and who were having to pay for medical treatment as private patients; and (2) whether his attention had been called to the letters of complaint constantly being received by Approved Societies from members who had not received medical tickets and who had not received any answer to the applications which they have made for the same upon the prescribed form; whether he was aware that in a number of such cases insured persons were being compelled to pay fees to panel doctors for treatment given before their medical card was received; and would he state what steps the Government proposed to take to deal with such cases?—Mr. WEDGWOOD BENN answered: Experience has shown that Approved Societies do not become aware of the changes of address of their members sufficiently early to render their notification to Insurance Committees of any value commensurate with the labour involved, and arrangements have accordingly been made under the system now established with the express object of enabling such notifications to be dispensed with. As I have already said, special procedure has been set up to enable insured persons who have not received medical cards to obtain them upon application, and my right honourable friend has no reason to believe that these arrangements are not adequate for the purpose. But if the honourable gentleman will furnish particulars of the cases referred to by him in which the applicants have not been promptly dealt with, he will cause inquiries to be made.

Motor Ambulances and Petrol Duty.

Mr. CROOKS asked the Chancellor of the Exchequer whether he would exempt from duty all the petrol spirit used by authorities under the Local Government Board which had a service of motor ambulances to convey patients to hospitals and infirmaries.—Mr. MONTAGU (Secretary to the Treasury) replied: My right honourable friend hopes to deal with this matter in the Revenue Bill.

TUESDAY, APRIL 21ST.

Institutions Approved for Medical Benefit.

Mr. SNOWDEN asked the honourable Member for St. George's-in-the-East, as representing the Insurance Commissioners, to state what number of institutions had been approved for medical benefit under Section 15, Subsection (4) of the National Insurance Act in England and Wales; the number of persons who had accepted this method of medical benefit; and the number of institutes which had received the full amount allowed for medical benefit.—Mr. WEDGWOOD BENN wrote in reply: 87 systems and institutions in England and Wales have been approved under Section 15 (4) of the National Insurance Act, 1911. The rest of the information asked for is not available.

Vaccination and Life Insurance.

Mr. SNOWDEN asked the Postmaster-General whether unvaccinated persons were granted annuities on more favourable terms than those who were vaccinated; and, if not, would he explain why this was not done, seeing that his department assumed on the recommendation of the National Debt Commissioners that those who were unvaccinated were more liable to contract small-pox and die from it than were the vaccinated.—Mr. HOBHOUSE answered: Annuities are granted on the same terms to vaccinated and unvaccinated persons. The applicant for an annuity is not required to furnish any evidence as regards health.

Mr. SNOWDEN also asked the right honourable gentleman whether his attention had been drawn to the fact that many of the principal life insurance offices did not now make any difference in the rates charged on the lives of unvaccinated as compared with vaccinated persons; whether he would state on what date the National Debt Commissioners recommended the differential treatment of unvaccinated persons as compared with the vaccinated under the life insurance scheme of the Post Office; whether he was aware that conscientious objection to vaccination had been recognised by the State since 1898; and whether he was aware that life insurance companies which did not impose restrictions of the character mentioned upon the assured were getting business which would otherwise be done through his department.—Mr. HOBHOUSE replied: I am aware that there is a diversity of practice amongst the life insurance offices with regard to the acceptance of proposals for life insurance from unvaccinated persons. The question of the acceptance of an unvaccinated person under the life insurance scheme of the Post Office first arose about two years ago.

WEDNESDAY, APRIL 22ND.

Cancer Research.

Captain FABER asked the Prime Minister whether, seeing that the disease of cancer had nearly doubled itself in the 30 years ending in 1910, and that the research into the disease was very costly, he would apportion a certain sum yearly for cancer research.—Mr. HERBERT LEWIS (Parliamentary Secretary to the Local Government Board) replied: A very large sum has been expended from voluntary sources for this purpose, and as at present advised my right honourable friend is not inclined to propose to the Treasury a State grant. He would, however, be glad to consider any representation on the subject which may be made by the honourable Member and others.

The Milk-Supply.

Mr. ASTOR in the evening proposed a motion calling attention to the unsatisfactory state of legislation and administration with reference to the milk-supply.

Mr. H. SAMUEL (President of the Local Government Board), in replying to the discussion, said that in a Bill which he would introduce before long a clause would provide that the Board of Agriculture should apply to imported milk similar restrictions to those imposed on home milk. In regard to compensation paid to farmers for the slaughter of tuberculous cows, it was recognised by the Board that the present form of Order was inadequate. The Board were on the point of issuing an amending Order which would grant compensation on more generous terms and assist the local authorities in their expenses in administering the Order. It was also necessary to trace back the tuberculous milk to the cow. The present provisions were most inadequate, and it was necessary to amend the law in that regard. In addition to tuberculosis, it was recognised that enteric fever, scarlet fever, and diphtheria were communicated by milk, and epidemics continued to be caused by infected milk. Further, dirty milk had a considerable bearing on the rate of infant mortality. All these matters needed to be dealt with. His department held the strongest view that it was essential that further measures should be taken to safeguard the health of the community. The law as to adulteration also required strengthening. Any Bill introduced should supersede the various local codes by uniform provisions. The Bill he hoped to introduce very shortly would be modified as compared with the Government's previous Bill so as to meet objections. The powers conferred were much more restricted. He proposed that the making of regulations should not rest with the Local Government Board alone, but that wherever the regulations touched the interests of farmers the concurrence of the Board of Agriculture should be required. Milk-sellers would be registered in order that their premises might be inspected, but he did not propose that they should be licensed. As to tuberculous milk he would take full powers to trace back the milk to its source and to deal effectively with the cows. He agreed that cost should not be imposed on the farmers. It was not a question of cost but of care. The Bill would enable samples of milk to be taken at any stage from the cow to the consumer. It would insist on the local authorities performing their duties, and the new grants in aid of rates ought to assist. Finally, it was hoped by the Bill to obtain uniformity in the law. As to certified milk, he would leave that open to be proposed as an amendment to the Bill if desired.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CROSSE, R. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Referee under the Workmen's Compensation Act, 1906, attached more particularly to the Wandsworth County Court in County Court Circuit No. 45, to act also for the Reading, Newbury, Farnham and Aldershot, and Chertsey County Courts, and one of the Medical Referees for County Court Circuit No. 52, attached more particularly to the Hungerford County Court.

HARWOOD-HARDMAN, FREDERICK, M.D. Edin., has been appointed Honorary Radiologist to the Croydon General Hospital.

HORTON, THOMAS, M.D., B.S. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Consulting Surgeon to the Torbay Hospital, Torquay.

JONES, HERBERT, L.R.C.S. Irel., D.P.H. Camb., has been appointed President of the Society of Medical Officers of Health.

MASTERMAN-WOOD, JAMES LETT, M.B., Ch.B. Edin., has been appointed Honorary Anæsthetist to the Torbay Hospital, Torquay.

NALL, JOHN FREDERICK, M.D. Durh., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Anæsthetist to the Torbay Hospital, Torquay.

SCRASE, J. J. SHIRT, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Scattered Homes by the Newton Abbot (Devon) Board of Guardians.

SPONG, AMBROSE, M.D. Manch., Ch.B., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Torbay Hospital.

TAYLOR, WILLIAM PEACH, L.M.S.S.A., has been appointed Honorary Surgeon to the Bristol Eye Dispensary.

WILLIAMS, RICHARD, L.R.C.P. Edin., M.R.C.S., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 29.

ERRATUM.—The announcement was made on April 4th that Dr. William Macewen had been appointed Epidemiologist to the Metropolitan Asylums Board. Dr. Macewen was appointed on April 1st, 1914, as a Temporary Medical Assistant in the Public Health Department of the London County Council, and we regret the appearance in our columns of the erroneous notice.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARGYLL, COUNTY OF.—Assistant County Medical Officer and Executive Tuberculosis Officer. Salary £300 per annum.

BARNSLEY, BECKETT HOSPITAL AND DISPENSARY.—Second House Surgeon, unmarried. Salary £100 per annum, with apartments, board, and laundry.

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £120 per annum, with residence, board, and laundry.

BEDFORD COUNTY HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

BETHNAL GREEN INFIRMARY AND WORKHOUSE, Cambridge Heath, E.—Assistant Medical Officer. Salary at rate of £120 per annum, with apartments, board, and washing.

BIRKENHEAD UNION INFIRMARY.—Senior Resident Assistant Medical Officer. Salary £150 per annum, with board, apartments, &c.

BIRMINGHAM CITY HOSPITAL, Lodge-road.—Assistant Resident Medical Officer. Salary £160 per annum, with board, residence, &c.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer and Resident Surgical Officer. Salary £80 per annum each, with board, washing, and attendance.

BIRMINGHAM, QUEEN'S HOSPITAL.—House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

BIRMINGHAM UNION.—DUDLEY-ROAD INFIRMARY: Resident Assistant Medical Officer. Salary £150 per annum, with apartments, rations, laundry, and attendance.

BOMBAY, BARODA, AND CENTRAL INDIA RAILWAY.—Medical Officer. Salary Rs.500 per calendar month.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.

BRADFORD ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing.

BRIGHTON PARISH POOR-LAW INSTITUTION, Elm Grove.—Resident Assistant Medical Officer, unmarried. Salary at rate of £140 per annum, with furnished house, rations, &c.

BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—Honorary Medical Clinical Assistant and Honorary Surgical Clinical Assistant.

BRISTOL CITY ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £200 per annum, with apartments, board, washing, and attendance.

BRISTOL CITY TUBERCULOSIS SCHEME.—Assistant Medical Officer. Salary £200 per annum, with board, rooms, and attendance.

BROADMOOR, CROWTHORNE, BERKS, STATE CRIMINAL LUNATIC ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £225 per annum, with quarters, coal, gas, and attendance.

BURNLEY, VICTORIA HOSPITAL.—Second House Surgeon for six months. Salary at rate of £100 per annum, with residence, board, and washing.

BURY INFIRMARY.—Junior House Surgeon. Salary £100 per annum, with board, residence, and washing.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with apartments.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, St. Pancras, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Resident House Surgeon. Salary £50 per annum, with board and laundry.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistants for three months.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £90 per annum, with board, apartments, and laundry.

CHICHESTER, WEST SUSSEX COUNTY MENTAL HOSPITAL.—Junior Assistant Medical Officer. Salary £200 to £250 per annum, with apartments, board, laundry, and attendance.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon, unmarried. Salary £140 per annum, with board, lodging, and laundry.

DERBY COUNTY ASYLUM, Mickleover, Derby.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

DERBY, COUNTY BOROUGH OF.—Junior Assistant Medical Officer of Health. Salary £150 per annum, with board and residence.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £50 for first six months, £75 for second six months, and at rate of £150 per annum during second year. Also Assistant House Surgeon, unmarried. Salary at rate of £75 per annum, with board and laundry.

DEWSBURY AND DISTRICT GENERAL INFIRMARY.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.

DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary £120 per annum, with board, residence, attendance, and washing.

DURHAM COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £200 per annum, with board, lodging, and washing.

DURHAM COUNTY COUNCIL.—Two School Medical Inspectors. Salary £300 per annum.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Surgeon for six months. Salary at rate of £75 per annum, with board, residence, laundry, &c. Also Medical Officer to Casualty Department for six months. Salary at rate of £100 per annum, with luncheon and tea provided.

ECCLES AND PATRICROFT HOSPITAL.—House Surgeon. Salary £70 per annum, with board, washing, and lodging.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £104 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—House Surgeon for six months. Salary at rate of £75 per annum, with board, residence, and washing.

HALIFAX ROYAL INFIRMARY.—Second House Surgeon and Third House Surgeon, unmarried. Salary £100 and £80 per annum respectively, with residence, board, and washing.

HALIFAX *UNION POOR-LAW* HOSPITAL, Salterhebble.—Resident Medical Officer. Salary £120 per annum, with apartments, rations, and washing.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, Haverstock Hill.—Clinical Assistant to Throat, Nose, and Ear Department for six months.

HASTINGS, EAST SUSSEX HOSPITAL.—House Physician. Salary at rate of £80 per annum, with residence, board, and washing.

HELLINGLY, EAST SUSSEX COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, washing, and attendance.

HOSPITAL FOR EPILEPSY AND PARALYSIS, *AND OTHER DISEASES OF* THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £75 per annum, with board, *lodging, and washing.*

HOSPITAL FOR WOMEN, Soho-square.—Clinical Assistants in Out-patient Department.

HUDDERSFIELD ROYAL INFIRMARY.—Assistant House Surgeon. Salary £80 per annum, with board, residence, and washing.

HUNTINGDONSHIRE COUNTY COUNCIL.—Assistant County Medical Officer and Assistant School Medical Officer (female). Salary £300 per annum.

KENT COUNTY COUNCIL.—Locum Tenens Tuberculosis Officer for four months. Salary at rate of £500 per annum.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum and board.

LEEDS GENERAL INFIRMARY.—House Surgeon for six months. Also House Surgeon. Board, residence, and laundry provided in each case. Also *Resident Medical Officer for six months at Ida and* Robert Arthington Hospitals. Salary £60 per annum, with board, residence, and laundry.

LEEDS, WEST RIDING ASYLUM, Menston.—Fourth Assistant Medical Officer. Salary £200 per annum, with board and apartments.

LEICESTER POOR-LAW INFIRMARY.—First Resident Assistant Medical Officer and Second Resident Assistant Medical Officer. Salary £200 and £150 per annum respectively, with rations, apartments, and washing.

LEICESTER ROYAL INFIRMARY.—Assistant House Surgeon for six months. Salary at rate of £100 per annum, with board, apartments, and washing.

MAIDSTONE, KENT COUNTY ASYLUM.—Fourth Assistant Medical Officer, unmarried. Salary £200 per annum, with quarters, attendance, washing, &c.

MALDON, ESSEX, MALDON UNION.—Medical Officer and Public Vaccinator. Salary £80 per annum.

MANCHESTER, BAGULEY SANATORIUM FOR TREATMENT OF TUBERCULOSIS.—Assistant Medical Officer. Salary £200 per annum, with board and residence.

MANCHESTER *CHILDREN'S HOSPITAL (OUT-PATIENTS' DEPARTMENT)*, Gartside-street, Manchester.—Senior Medical Officer. Salary £180 per annum. Also Assistant Medical Officer for six months. Salary £50 per annum.

MIDDLESBOROUGH, NORTH ORMESBY HOSPITAL.—Assistant House Surgeon. Salary at rate of £100 per annum first six months and £110 per annum afterwards, with board, apartments, washing, and attendance.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.—Assistant Dental Surgeon.

NATIONAL SANATORIUM, Benenden, Kent.—Assistant Medical Officer. Salary £120 per annum, with board, residence, and laundry.

NEWARK-UPON-TRENT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and laundry.

NEWCASTLE-UPON-TYNE HOSPITAL FOR SICK CHILDREN.—Honorary Assistant Surgeon. Also Junior Medical Officer for six months. Salary £80 per annum, with board, lodging, and laundry.

NOTTINGHAM CITY ASYLUM.—Locum Tenens Assistant Medical Officer for about three months. Salary £5 5s. per week, with apartments, board, and washing.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, residence, and laundry.

OLDHAM ROYAL INFIRMARY.—Senior House Surgeon and Second House Surgeon for six months. Salary £140 and £120 per annum respectively, with residence, board, and laundry.

PADDINGTON GREEN CHILDREN'S *HOSPITAL*, London, W.—House Physician and House Surgeon for six months. Salary at rate of £52 10s. each per annum, with board and residence.

PEMBROKESHIRE EDUCATION AUTHORITY.—*Assistant School Medical* Officer. Salary £300 per annum.

PETERBOROUGH INFIRMARY AND DISPENSARY.—House Surgeon, unmarried. Salary at rate of £120 per annum, with *residence*, board, and laundry.

PORTSMOUTH CORPORATION MENTAL HOSPITAL.—Assistant Medical Officer, unmarried. Salary £225 per annum, with board, apartments, attendance, and washing.

PORTSMOUTH WORKHOUSE INFIRMARY, WORKHOUSE, AND CHILDREN'S HOME.—Second Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with apartments, rations, &c.

PRESTON ROYAL INFIRMARY.—Resident Medical and Surgical Officer, unmarried. Salary £150 per annum, with board, residence, and laundry.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Pathologist. Salary 120 guineas per annum. Also Honorary Medical Registrar.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road.—House Physician for six months. Salary at rate of £80 per annum, with board, residence, and washing.

READING, ROYAL BERKSHIRE HOSPITAL.—Second House Surgeon for six months. Salary at rate of £80 per annum, with lodging, board, and washing.

ROCHDALE INFIRMARY.—Senior House Surgeon, unmarried. Salary £110 per annum, with board, residence, and laundry.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.

ROYAL INSTITUTE OF PUBLIC HEALTH, *Russell-square*, W.C.—Assistant Director of the Bacteriological Laboratories. Salary £250 per annum.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Honorary Physicians.

ST. MARK'S HOSPITAL FOR CANCER, *FISTULA*, AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ST. PANCRAS SOUTH *INFIRMARY* AND WORKHOUSE, Pancras-road.—Senior Assistant Medical Superintendent and Senior Assistant Medical Officer. Salary at rate of £175 per annum, with residential *allowances.*

SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, lodging, and washing.

SHEFFIELD, EAST END BRANCH OF THE CHILDREN'S HOSPITAL.—House Surgeon for Out-patient Department. Salary £100 per annum, with board and residence.

SHEFFIELD ROYAL INFIRMARY.—Ophthalmic House Surgeon for six months. Salary £80 per annum, with board and residence.

SHEFFIELD, SOUTH YORKSHIRE ASYLUM, Wadsley.—Locum Tenens Assistant Medical Officer for five months. Salary £5 5s. per week, with apartments, board, and attendance.

SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, rations, &c.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon. Salary at rate of £100 per annum, with rooms, board, and washing.

STOCKPORT, COUNTY BOROUGH OF.—Tuberculosis Officer. Salary £400 per annum.

TOTTENHAM EDUCATION COMMITTEE.—Assistant School Medical Officer. *Salary £300 per annum.*

TRINIDAD, BRITISH WEST INDIES.—Three Medical Officers required to Conduct Campaign against Ankylostomiasis. Medical Officer in Charge, salary £600 per annum. Two Assistant *Medical Officers*, salaries £400 per annum.

TUNBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, &c.

WALSALL AND DISTRICT HOSPITAL.—Senior House Surgeon and Assistant House Surgeon. Salary £150 and £110 per annum respectively, with board, residence, and laundry.

WARRINGTON, LANCASHIRE COUNTY ASYLUM, Winwick.—Locum Tenens Medical Officer, unmarried, for about five months. Salary 6 guineas per week, with board, apartments, attendance, and washing.

WEST HAM UNION SICK HOME, Forest-lane, Forest Gate.—Second Assistant Resident Medical Officer. Salary £160 per annum. Also Female Assistant Medical Officer at Workhouse, Union-road, Leytonstone, N.E. Salary £140 per annum.

WEST LONDON HOSPITAL, Hammersmith, W.—Ophthalmic Surgeon. Also Resident Casualty Officer for six months. Board, lodging, and *laundry provided.*

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £100 per annum, with board, apartments, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer. Also Two House Surgeons for six months. Salary in each case at rate of *£125 per annum*, with board, rooms, and laundry.

WREXHAM INFIRMARY.—Resident House Surgeon. Salary £120 per annum, with board, lodging, and *washing.*

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Llanwrtyd Wells, in the county of Brecknock.

Births, Marriages, and Deaths.

BIRTHS.

DAVIS.—On April 20th, at Darelan, West Heath Drive, Hampstead, the *wife of* Edward D. Davis, F.R.C.S., of a son.

MCALLUM.—On April 15th, at Scotswood, Milford-on-Sea, *the wife* of J. H. McAllum, M.R.C.S., of a daughter.

SLATER.—On April 14th, at Holme *Top* House, Bradford, Yorkshire, Ella (neé Beales), the wife of B. Holroyd Slater, B.A., M.B., F.R.C.S., of a daughter.

MARRIAGES.

FOWLER—STONE.—On April 18th, at All Saints', Isleworth, Middlesex, Oliver H. Fowler, M.R.C.S. Eng., to Helen Grace Stone, daughter of C. Stone, Lancing, Worthy-road, Winchester.

WALKER—HARDING.—On April 15th, at Woodford Parish Church, Gerald Walker, M.A., M.B., D.P.H. Cantab., to Gertrude, second daughter of Mr. and Mrs. Charles F. Harding, of Churchfields, Woodford.

DEATHS.

GRIFFITHS.—On April 17th, at Ferncoombe, Bournemouth, *Thomas* Druslyn Griffiths, M.D. Lond., D.Sc. Oxon., in his 78th year.

LEES.—On April 15th, at South-side, *Clapham* Common, S.W., suddenly, Dr. Joseph Lees.

MATCHETT.—On April 15th, at Nether Stowey, Anwyl *Charles* Matchett, M.B., C.M., aged 45.

PEARSE.—On April 14th, 1914, at Torquay, Thomas Fredk. *Pearse*, M.D., F.R.C.S. Eng., late Medical Officer of Health, Calcutta, aged 57 years. Indian papers please copy.

WILLIAMS.—On April 20th, at Bennett Park, Blackheath, *Hutchins* Williams, M.D. Edin., M.R.C.S. Eng., L.R.C.P. Lond., in his [illegible] year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"GUY'S MEN."

THERE are few things more helpful to the continuance of worthy effort than a long line of honourable tradition of achievement, fostered in each succeeding generation by the presence of a standing object lesson rather than by precept. The plan which has been adopted at Guy's Hospital of collecting and placing in special bookcases near the entrance to the Wills library books written by Guy's men is calculated to subserve this end and is worthy of commendation and imitation elsewhere. Mr. William Wale, librarian of Guy's Hospital, has contributed to the Guy's Hospital Reports (Guy's Hospital Reports, 1913, vol. lxvii. (reprint)) an annotated list of these books, including under the term Guy's men "those who have at any time been connected with the hospital, either as students or in an official capacity." Garrison ("Richard Bright's Travels in Lower Hungary; a Physician's Holiday," *Johns Hopkins Hospital Bulletin*, June, 1912) has pointed out that the special achievement of the men of Guy's lay in the department of original descriptions of disease. Addison's description of suprarenal disease, Bostock's—the first complete one—of hay fever, Bright's penetrating observation not only of morbus brightii, but of acute yellow atrophy of the liver and other conditions, Hodgkin's account of the disease that bears his name, all so philosophic in breadth of grasp, Pavy's researches on diabetes, Wilks's descriptions of post-mortem appearances in disease, not to mention more recent work of many still among us, at once come to mind. But Mr. Wale's notes furnish us also with some interesting items of medical gossip. In the matter of "records," Thomas Bell (1792–1880), of Guy's, according to Sir John Erichsen, was the first to apply the general rules of surgery to the art of dentistry, while Joseph Fox, also of Guy's, was probably the first dentist in England to write a scientific work on the teeth (1803) and give lectures at a medical school. To Guy's also belongs the honour of having furnished the first trials in this country of static electricity in disease (Addison and Golding-Bird, 1837), the first gastrostomy in England (Cooper Forster, 1858), the first discovery of albuminous urine in puerperal eclampsia (J. C. W. Lever, 1843), the first publication of annual hospital reports, the first President of the Royal Medico-Chirurgical Society (Williams Saunders, 1805) and of the Epidemiological Society (Dr. Babington, jun.), and the first course of lectures in English on medical jurisprudence (Alfred Swaine Taylor, 1831). There is in the library, it need hardly be said, a complete series of the poetical works of John Keats; also a life of the Rev. Frederick Denison Maurice, who was chaplain to Guy's from 1836-46. It is worthy of note that Thomas Hodgkin was offered the Fellowship of the Royal College of Physicians in 1836, but declined to accept an honour which, in his opinion, created an invidious distinction; while equally noteworthy is the fact that when Golding-Bird, at the age of 21, submitted himself for examination for the L.S.A., that body, in view of his already established reputation, declined to examine him and conferred its licence on him with "the honours of the court." We learn also that the founder of the hospital, Thomas Guy, has at least thrice been credited with saintship, for "St. Guy's Hospital" is referred to in the register of Deadman's Place Meeting House (1758), in an essay by Thomas Sutton, M.D. (1813), and in a letter from Sir Robert Peel, then Prime Minister, to Queen Victoria (1845). But Mr. Cuthbert Golding-Bird, who points out the first of these mistakes, incontinently makes a knight instead of a saint of him—Sir Thomas Guy, knight. A very interesting note is Sir Astley Cooper's estimate of himself, found among his private papers after his death: "Sir A. Cooper," it reads, "was a good anatomist, but never was a good operator where delicacy was required. He felt too much before he began, ever to make a perfect operator. Quickness of perception was his forte, for he saw the nature of disease in an instant, and often gave offence by pouncing at once upon his opinion. The same faculty made his prognosis good. He was a good anatomist of morbid as well as of natural structure. He had an excellent and useful memory. In imagination he was vivid. His principle in practice was never to suffer any who consulted him to quit him without giving them satisfaction on the nature and proper treatment of their case. My own success depended upon my zeal and industry, but for this I take no credit, as it was given to me from above." A note of striking present interest is on the flyleaf of Dr. Robert John Thornton's "Easy Introduction to the Science of Botany" (1823): "This book contains a singular discussion as to whether it is decent to teach girls botany, seeing that plants have sexual organs and functions."

"ON A BUSINESS FOOTING."

A WELL-KNOWN consulting surgeon recently received the following communication, type-written, from a person of whom he had never previously heard. We suppress all names, but publish the letter as a good illustration of the profound belief that some members of the public have in the venality of the doctor.

> DEAR SIR,—Dr. A——, of B——, has advised me to write to you to inform you that I am willing to receive a delicate lady or convalescent patient, with or without nurse companion, as paying guest. —— House is delightfully situated, standing high in own grounds, commanding superb views over moorlands. Good tennis-court, orchard, flower garden, and meadows. Young companionship with my daughters, who speak perfect idiomatic French, and would coach in same. We are ten minutes from C——, and close to beautiful inland country and scenery. Close to golf and tennis clubs. Hunting with two packs. Good sea and river fishing. We live exceedingly well and most liberal table kept. I myself had hospital training many years ago, and all my life had much experience with illness and nursing, and would ensure that a delicate guest received every care and attention.
>
> Our climate is mild in winter. ...... We have an invigorating mixture of sea and moorland air which is restful and yet health-giving for convalescents or nerve patients, who rapidly regain health and strength. ...... Dr. A—— will be pleased at any time to answer questions and act as referee, and we are also well known to, and personal friends with, the Vicar of D——, who would also act as referee.
>
> I might mention that in return for any kind assistance you may give me by recommendation and sending me patients, I should like all to be on a business footing and for there to be a liberal commission on every guest—a definite fee to you on arrival of guest, followed by regular weekly commission throughout the visit. Trusting that you may be able to send me guests (I am willing to take two, but not more),
>
> Yours faithfully, (Lady) —— ——.

We are perfectly certain that Lady —— has no idea that her letter is a concentrated insult. From her point of view she is making an ordinary commercial offer.

PLANE TREES AND DISEASE.

WE observe that this week the question has been again raised whether the broken fruit spicules of the plane trees floating in the air in parts of London give rise to inflammation of the eyes and air passages. We referred at some length to this question in an annotation published in THE LANCET of May 14th, 1910, p. 1363, when we said that the evidence adduced was far from convincing, although there was nothing inherently improbable in the suggestion. At the same time we hoped that the character of these trees would be vindicated, as they grow well in London and are a welcome addition to our streets and parks.

THE LEBANON HOSPITAL FOR THE INSANE.

THE efforts of Mr. Theophilus Waldemeier, the founder of the Brumana station of the Friends' Foreign Missionary Society, warmly seconded by workers of all nationalities in Syria and by many friends in England, America, Switzerland, and elsewhere, resulted in the opening of the Asfuriyeh Asylum in August, 1900. This is to this day the only hospital for the insane in Syria or Palestine, and no other on a similar plan exists in the Ottoman Empire, though several hospitals in the capital have wards for the insane. The hospital property, of 36 acres, is situated about five miles from Beirut, at an elevation of some 400 feet above the sea, in a most healthful region, and has a good supply of water. It has now accommodation for 100 patients. A new building is being erected for 30 more men. The hospital is always overcrowded, and men and women have constantly to be turned away. Last year 201 patients enjoyed the benefits of this hospital, of whom 95 were remaining from the preceding year. Of the 106 new cases, 66 were men and 40 women. 103 remained at the end of the year under consideration. Of the other 98, 24 were discharged cured, 18 improved, 40 unimproved, while 14 died. Two others admitted were found to be not insane. In the 12 years from its opening to 1912, over 1000 patients have been received, of whom 290 have recovered and 241 have been dismissed improved. This 1000 represent a wide geographical area, for besides the large number from the Lebanon district and Beirut, many have come from Damascus, Sidon, Baalbek, Tarsus, Cæsarea, Adana, Marash, Aleppo, Egypt, Cyprus, and further away. They represent many religions, too. Thus, there have been 364 orthodox, 259 Maronites, 161 Moslems, 86 Jews, 84 Roman Catholics, 62 Protestants, 13 Druses, and 6 Armenians. These figures show the international and undenominational nature of the enterprise. The executive committee of the hospital is in Beirut, and consists of

Dr. Webster, Dr. Moore, Dr. Graham, Dr. Adams, and Dr. Hoskins. This committee works in connexion with a general committee in London, of which Miss A. M. Gooch is the general secretary. The income from invested funds is £230 annually, and the annual subscriptions and donations amount to £1230. In spite of the fact that one-third of the patients are utterly destitute and another third pay extremely little, the income from patients stands at £2070, a most encouraging showing. Yet it will be seen that these amounts are far too small for an institution of the size and possibilities of this one. Another £1040 yearly is very much needed.

THE PRINTING AND ALLIED TRADES EXHIBITION.

THIS exhibition, to be opened at the Royal Agricultural Hall by the Lord Mayor of London on May 13th, will be the largest and most representative exhibition of its kind ever held, every available space in the Great Hall, the Gilbey Hall, King Edward's Hall, and the galleries being occupied with exhibits strictly appertaining to the graphic arts. New machinery and appliances will be shown alike interesting to the expert and the general public, in addition to a very fine display of specimens of printing by all processes, including photogravure. The exhibition has the support of the various societies associated with the printing and allied trades, and most firms of repute in the industries represented are co-operating, we understand, to make this quadrennial exhibition a success.

"VIROLAX."

IN our analytical report of this preparation last week we stated that analysis gave 36 per cent. of total unsaponifiable oil (petroleum). This result is by weight, which substantiates the claim that virolax contains approximately 50 per cent. by volume of petroleum.

◆

Parathalassa.—Theocin-sodio-acetate, or, to give it its full name, theophylline-sodium-sodio-acetate, is a compound of sodium acetate and theophylline (di-methyl xanthine), an alkaloid obtained by synthesis (patented), and called generally theocin, which is isomeric with theobromine. (Reported favourably upon for œdema and dropsy of cardiac origin and as seldom causing unpleasant effects.) Theobromine sodium salicylate (diuretin) is a compound of the true theobromine with sodium salicylate, a diuretic which given in small doses causes sleeplessness without affecting the nervous system. It has been described as a safe diuretic in scarlatinal dropsy of children. These preparations are generally conceded to be more powerful diuretics than the ordinary tartrates, acetates, and citrates.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 27th–May 1st (London, Royal Horticultural Hall).—Nursing Conference and Exhibition.
May 1st–Nov. 1st (Lyons).—International Town Hygiene Exhibition.
,, 15th–Oct. 15th (Berne).—Swiss National Exhibition.
,, 18th–21st (London, Imperial Institute).—Victoria League Imperial Health Conference.
May–October (London, Shepherd's Bush).—Anglo-American Exposition.

METEOROLOGICAL READINGS.

(*Taken daily at 8.30 a.m. by Steward's Instruments.*)

The following journals, magazines, &c., have been received:—British Journal of Nervous and Mental Disease, Medical Chronicle, British Journal of Dental Science, American Journal of Orthopedic Surgery, Quarterly American Medicine, Therapist, London Hospital Gazette, Quarterly of the Federation of State Medical Boards of the United States, British Indian Medical Record, Revista Especialidades Médicas, British Dental Journal, Journal of Obstetrics and Gynæcology of the British Empire, Surgery, Gynecology and Obstetrics, Archives of Pediatrics, Office International d'Hygiène Publique, Knowledge, &c.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London W.

THURSDAY.—Dr. J. C. Willis: On the Lack of Adaptation in the Tristichaceæ and Podostemaceæ (communicated by Dr. D. H. Scott, foreign secretary to the Royal Society).—Mr. R. P. Gregory: On the Genetics of Tetraploid Plants in Primula Sinensis (communicated by Prof. W. Bateson).—Mr. J. A. Gunn: The Action of Certain Drugs on the Isolated Human Uterus (communicated by Prof. C. S. Sherrington).—Prof. B. Moore: The Presence of Inorganic Iron Compounds in the Chloroplasts of the Green Cells of Plants, considered in Relationship to Natural Photo-synthesis and the Origin of Life.—Mr. D. J. Lloyd: The Influence of Osmotic Pressure upon the Regeneration of Gunda Ulvæ (communicated by Prof. J. S. Gardiner).—Surgeon-General Sir D. Bruce, Major A. E. Hamerton, Captain D. P. Watson, and Lady Bruce: (1) Glossina Brevipalpis as a Carrier of Trypanosome Disease in Nyasaland; (2) Trypanosome Diseases of Domestic Animals in Nyasaland. Trypanosoma Pecorum—Part III., Development in Glossina Morsitans.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SECTION OF ODONTOLOGY (Hon. Secretaries—Robert McKay, F. Coleman): at 8 P.M.

Casual Communications:

By Mr. W. H. Dolamore, Mr. G. Northcroft, Mr. F. N. Doubleday, Mr. H. C. Visick, Mr. Wm. de C. Prideaux.

TUESDAY.

SECTION OF MEDICINE (Hon. Secretaries—H. Batty Shaw, John Fawcett): at 5.30 P.M.

Dr. E. P. Poulton: Observations on CO_2 in Alveolar Air of Diabetics, especially in Relation to Onset of Coma, with Demonstration of Fridericia's Method of Measuring it Clinically.

Dr. F. Parkes Weber: (1) Aplastic Anæmia; (2) Multiple Superficial Linear Ulceration of the Stomach.

Dr. J. A. Braxton Hicks: A Pedunculated Intratracheal Tumour (Sarcoma) causing Bronchiectasis.

FRIDAY.

SECTION OF LARYNGOLOGY (Hon. Secretaries—E. A. Peters Cecil I. Graham): at 4 P.M.

Annual Meeting.—Election of Officers and Council for Session 1914–1915.

Cases:

Will be shown by Dr. Milligan, Dr. Jobson Horne, Dr. E. A. Peters, and others.

(The SEMON LECTURE (University of London) will be given on May 28th by Professor Killian (of Berlin) on Suspension Laryngoscopy.)

SECTION OF ANÆSTHETICS (Hon. Secretaries—H. E. G. Boyle, Cecil Hughes): at 8.30 P.M.

Paper:

Dr. Goodman Levy: Sudden Death under Chloroform Anæsthesia.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Dr. P. Stewart: Recent Treatment of Cerebro-Spinal Syphilis and General Paralysis.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Paper:—Mr. E. Clarke: Errors in Diagnosis and Treatment in Ophthalmic Practice.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., Members are invited to show cases. Paper:—Dr. F. G. Crookshank: Exophthalmic Goitre, its Pathogeny and Treatment.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Papilloma and Adenoma. (Museum Demonstration.)

FRIDAY.—5 P.M., Prof. Keith: Various Forms of Peritoneal Adhesions, Bands, and Mesenteries. (Museum Demonstration.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. 2.30 P.M., Mr. P. Harman: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. H. B. Carlill: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin. ——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.15 P.M., Sir Malcolm Morris: Skin. 4.30 P.M., Special Lecture:—Mr. A. Carless: Renal Emergencies.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. B. Carlill: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. H. R. Prentice: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Special Lecture:—Dr. R. Wells: Auricular Fibrillation. 4.30 P.M., Special Lecture:—Mr. J. Cantlie: Affections of the Colon in Tropical Ailments and their Treatment.

FRIDAY.—Out-patient Demonstrations:—10 A.M., Dr. C. E. Zundel: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin. ——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford: Medicine. 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. H. R. Prentice: Medical. Mr. Cecil Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, Medical School, City-road, E.C.

MONDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Cardiac Department, Dr. Stott; Out-patient Department, Dr. Phear, Dr. S. Thompson. 3 P.M., Wards, Dr. Phear.

TUESDAY.—9 A.M., Laryngological Department, Mr. Mant. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. M. Leslie, Dr. B. King; Operations, Mr. A. Evans. 3 P.M., Wards, Dr. White. 4 P.M., Wards, Dr. M. Leslie

WEDNESDAY.—2 P.M., Wards, Dr. A. Davies; Out-patient Department, Dr. Drysdale, Dr. Kellie. 4 P.M., Wards, Dr. Drysdale. 4.30 P.M., Roentgen Ray Department, Dr. Jordan.

THURSDAY.—9.30 A.M., Dental Department, Mr. G. Thomson. 10 A.M., Cardiac Department, Dr. Stott. 1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Out-patient Department, Dr. Phear, Dr. S. Thompson. 4.30 P.M. Laryngological Department, Mr. Mant.

FRIDAY.—1.30 P.M., Department for the Prevention of Consumption. 2 P.M., Wards, Dr. Calvert: Out-patient Department, Dr. M. Leslie, Dr. B. King. 5 P.M., Lecture-Demonstration:—Dr. Drysdale: Myocarditis and its Symptoms.

SATURDAY.—10 A.M., Out-patient Department, Dr. Drysdale, Dr. Kellie. 11.30 A.M., Roentgen Ray Department, Dr. Jordan.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

LONDON LOCK HOSPITAL, 91, Dean-street, Soho, W.

Special Course of Instruction in Venereal Diseases, for Post-Graduates and Students, with Practical Demonstrations of the Various Methods of Treatment:—

MONDAY.—Clinics:—2 P.M., Mr. Ryall; 6 P.M., Mr. Gibbs. Lecture:— 5 P.M., Mr. Gibbs: The Treatment of Acute Gonorrhœa.
TUESDAY.—Clinics:—2 P.M., Mr. Lane; 6 P.M., Mr. Paterson.
WEDNESDAY.—Clinic:—6 P.M., Mr. Shillitoe.
SATURDAY.—Clinic:—2 P.M., Mr. McDonagh.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

TUESDAY.—7 P.M., Lecture:—Dr. J. Kerr: Health of the School Child.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

TUESDAY.—MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES, Quay-street.—4.30 P.M., Prof. R. B. Wild: Lupus Erythematosus.

WEDNESDAY.—ROYAL INFIRMARY.—4.30 P.M., Dr. Tylecote: Demonstration of Medical Cases.

THURSDAY.—ANCOATS HOSPITAL.—4.30 P.M., The Honorary Surgical Staff: Demonstration of Cases.

FRIDAY.—ROYAL EYE HOSPITAL.—4.30 P.M., Dr. H. Griffith: Diseases of Cornea.

UNIVERSITY OF SHEFFIELD, at the University.

Post-Graduate Course on Syphilis:—

TUESDAY.—3 P.M., Prof. Dean: Principles of Serum Reactions in General. Ehrlich's Side-chain Theory. Complement Fixation. The Wassermann Reaction.

FRIDAY.—3 P.M., Prof. Dean: Practical Demonstration of Methods of Collecting Blood, and Technique of Wassermann Reaction.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Version and Extraction. 11 A.M., Examination of Patients and Minor Operations.
TUESDAY.—10 A.M., Major Operations.
WEDNESDAY.—10 A.M., Obstetrical Lecture: Version and Extraction (continued). 11 A.M., Examination of Patients and Minor Operations.
THURSDAY.—10 A.M., Major Operations.
FRIDAY.—10 A.M., Gynæcological Lecture: Pelvic Infection. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the *Proprietors* any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. J. Astier, Asnières; Mrs. Arney, Farnborough; Mr. E. Arnold, Lond.; Dr. Percy Allan, Lond.; Apothecaries' Hall, Dublin, Registrar of; Dr. Armly Ashkenny, Birmingham; Messrs. Arnold and Sons, Lond.

B.—Mr. E. Bougault, Paris; Messrs. Burgoyne, Burbidges, and Co., Lond.; Berliet Motors, Lond.; Messrs. Battle and Co., Brussels; Birmingham Corporation, Medical Superintendent of; Messrs. J. Beal and Son, Brighton; Mr. Arthur E. Barker, Lond.; Messrs. A. Bishop, Lond.; Dr. P. H. Bryce, Ottawa; Mr. H. G. Barrett, Watford; Buckingham, Medical Officer of Health of; Mr. D. L. Beckingsale, Lond.; British Viavi Co., Lond.; Bayer Co., Lond.; Bristol Corporation, Medical Officer of Health of.

C.—Dr. W. H. Coltart, Warwick; Messrs. C. D. Clayton, Lond.; Mr. H. A. Collins, Croydon; Messrs. Clement Talbot and Co., Lond.; Messrs. G. The Lumleian Lectures

ON

SOME MODERN THEORIES CONCERNING HYSTERIA.

Delivered before the Royal College of Physicians of London on March 19th, 24th, and 26th, 1914,

BY J. A. ORMEROD, M.D. OXON.,
F.R.C.P. LOND.,

REGISTRAR TO THE COLLEGE; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE.

LECTURE II.[1]

Delivered on March 24th.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—In my first lecture I considered some of the most striking symptoms of hysteria with the view of showing the difficulty in choosing absolutely between the two alternative methods of explaining them—namely, the physiological and the psychological. I must now turn to the various theories that have been propounded about this disease, limiting myself for brevity's sake to a few, and to recent theories only.

Briquet, the pioneer in modern studies of hysteria, says that it is a disorder of that part of the nervous system which subserves the emotions. Dejerine says: "What emotion can produce as temporary effects, hysteria can produce as lasting effects." Sir Bryan Donkin lays stress on exaggerated impressionability or tumultuous emotion as a principal factor in the disease. Oppenheim holds that hysteria is a disorder of the mind, principally affecting the emotional sphere, and consisting in a want of proportion between the intensity of the stimulus and the strength of the reaction.

Russell Reynolds, Charcot, and Moebius all emphasised the importance of "ideas" in producing hysterical symptoms. Bernheim and Babinski find the keynote in "suggestion." Sollier maintains that there is a torpor of the brain, local or general. Dr. S. J. Sharkey looks on hysteria as a peculiar condition of the brain in which the current or nerve force is distributed in an irregular and fluctuating way, so that some centres are apt to be flooded, others left high and dry, the result being in the one case overaction, in the other paralysis.

Dr. Parkes Weber, regarding hysteria from the point of view of phylogenesis, suggests that it is a sort of secondary sexual character.

Most of these opinions, valuable as they are, have not been elaborated into precise theories, so as to explain in detail the wonderful variety of symptoms which meets us in this disease. Let us go on then to authors who aim at more detailed explanation of the facts.

PHYSIOLOGICAL VIEWS.

Dr. Charlton Bastian[2] studies hysteria from the point of view of anatomy and physiology. He thinks, however, that the term "hysterical" should not be applied to all nervous affections for which we cannot find an organic cause; there are some which we may justly term functional, but not hysterical. The class of cases which he would thus detach from hysteria is a limited but very important one—viz., paralyses, motor and sensory. One reason given for thus detaching them is that such paralyses may often be found in patients who exhibit no other symptoms—no fits, that is, nor mental peculiarities, such as proneness to exaggeration or caprice, which Bastian apparently considers to be most characteristic of hysteria. Further, whereas hysteria is generally considered to be a perversion of the highest cerebral functions, these paralyses can, in his view, be shown to depend on local affections of the nervous system, and that not only of the cerebral cortex, but also of the lower centres and of the afferent nerve fibres. I alluded in my first lecture to certain similarities between hysterical and organic paraplegia; these and other similarities between hysterical and organic paralysis are studied by Bastian in detail and in a most interesting series of cases. I must be very brief in considering these.

A young woman was unable to move her right arm. There was (at the time of observation) very little sensory loss, except that there was loss of muscular sense in that arm. There was no rigidity. She stated that she could imagine or picture to herself movements of the left (non-paralysed) arm, but could not imagine movements of the right. This type of monoplegia corresponds to the effects of a local lesion in the arm centre of the left Rolandic area—an area which, in Dr. Bastian's view, is not so much motor in function as kinæsthetic. Movements were no longer possible, because the memories of movements were annulled.

We may take other kinds of case. The hemianæsthesia so common in hysterical cases would be explained as a failure of function in the posterior part of the opposite internal capsule, and a paraplegia, unaccompanied by loss of sensation, but accompanied by rigidity, as a failure of function in the pyramidal tracts of the cord.

Consideration of So-called Functional Paralysis.

Any views enunciated by a physician of Dr. Bastian's experience, and enforced by the cogency of argument whereof he is a master, must deserve the greatest respect. Yet I cannot altogether bring myself to agree with him in separating these forms of so-called functional paralysis from hysteria. His arguments for so doing are mainly two. First, that the affection is a local one. But is this satisfactorily proved? Take the fairly common case of a hysterical hemiplegia, which is generally incomplete and non-spastic, but combined with a hemianæsthesia which is often very marked. On the localising hypothesis there must be two lesions, one in the Rolandic centre and another in the sensory part of the internal capsule. Does not the necessity for supposing two lesions indicate a weak spot in the localising hypothesis? Again, take the spastic cases, and particularly spastic paraplegia. We cannot thoroughly discuss these without reference to Babinski's sign (the extensor plantar reflex). The presence or absence of this is not mentioned by Bastian, for the very good reason that the sign was not known at the time when he wrote. Still, knowing, as we now do, that Babinski's sign is always absent in functional disease, we may assume that it would not have been found in Bastian's cases. Here, then, would be a contradiction; rigidity is present, and from its presence we are asked to infer an abnormal condition of the pyramidal tracts, but Babinski's sign, a far more delicate index of the condition of the pyramidal tracts, is absent. Take, again, the symptom of anæsthesia. If this symptom (as I endeavoured to show in my first lecture) is in a sense unreal—i.e., that many of these patients feel, though they do not know that they feel—surely this

---

[1] Lecture I. was published in THE LANCET of April 25th, 1914, p. 1153.

[2] Hysterical or Functional Paralysis. London: H. K. Lewis, 1893.

No. 4731.

militates against the notion of a local lesion, even of a "functional" nature, in the afferent tracts. For how can nerve fibres be so damaged as to bar the transmission of conscious sensations and at the same time let the subconscious sensations through? Lastly, it appears that such paralyses, whether motor or sensory, have been made and unmade by hypnotic suggestion. It is difficult to suppose that such an action takes place in the conducting fibres or anywhere else than in the highest centres.

Dr. Bastian's other reason for refusing to call these forms of paralysis hysterical is that many such patients have no hysterical fits and exhibit no hysterical temperament. But others of them certainly do have fits, and what is more to the point, occasionally a paralysis of this kind appears as the direct sequel of a hysterical fit. About a patient's temperament it is often difficult to be sure without an intimate personal knowledge. Besides there are some patients whom with Charcot we must recognise as "*hystériques placides*." Lastly, in the history of these hysterical paralytics we often find the same sequence of events as in typical hysteria—namely, a neuropathic family history, disappointments, grief, anxiety, fright, ill-health, traumatisms, and (shall I say it?) surgical operations. So that I would still continue to class them as hysterical.

Pathogenesis of Functional Paralysis.

As to the pathogenesis of this functional paralysis, apart from the localisation of it, Dr. Bastian speaks with reserve. He considers (without entirely adopting it) the hypothesis of a vaso-motor spasm causing local defect of function. That hypothesis is naturally suggested by the sudden appearance and disappearance of the symptoms which we often witness. Against it stand the cases where the paralysis lasts for months or years. Another hypothesis is that of a local malnutrition of the affected nerve areas, primary and not dependent upon any change in the blood-supply, just sufficient to interfere with proper function, but not sufficient to produce structural disorganisation. But we do not know, I think, of any such kind of malnutrition; and moreover the sudden and unaccountable changes which sometimes occur in such cases are very difficult to explain on the basis of a malnutrition, whether from vaso-motor or other cause.

I give as an illustration of this curious changeability the following case of hysterical aphemia or mutism. It will be remembered that Dr. Bastian has pointed out that this particular symptom of mutism, as we see it in hysteria, is just what would be produced by a local lesion of the fibres leading downwards from Broca's convolution to the bulbar nuclei. My case is quoted by Dr. Kinnier Wilson in his article on Hysteria in *Brain* (Vol. XXXIII., p. 312).

A young woman, intelligent, quiet, apparently unexcitable, and anxious to get well, was admitted under my care at Queen-square for an incomplete hysterical hemiplegia. After some weeks she began to stammer. To stop this faradisation was applied. The result was unexpected, for she suddenly became unable to utter a word, as dumb as the son of Crœsus in Herodotus, or as the priest Zacharias in the Gospel of St. Luke. The sister of the ward invented a treatment of her own—namely, to manipulate the patient's tongue. One day, while this was being done, she recovered her speech. But such a speech! A loud, harsh, syllabic monotone, produced with a mouthing and an effort, which was most unpleasant both to hear and to see—"*δεινὸς μὲν ὁρᾶν, δεινὸς δὲ κλύειν.*" It was so disagreeable, in fact, that for the sake of the other patients her hours of speech had to be curtailed; and finally, as it seemed necessary to do something, she was given an anæsthetic, together with the firm assurance that when she came round she would speak quite well. But again the unexpected happened, for when she came round she was completely dumb again, and in spite of all persuasion, whether in hypnosis or otherwise, dumb she remained up to the date of her discharge and for some weeks after. Then the final turn of the wheel came in the following curious way. She happened to find unexpectedly in a drawer a lost picture of her deceased father, concerning which she and the aunt with whom she lived had had frequent discussions as to whether the face looked to the right or to the left. On finding it she said suddenly, "Look, auntie, I was right," and soon afterwards she recovered her speech entirely.

Now I can hardly think that a local variation of blood supply, still less a local malnutrition of nerve fibres, was responsible for all these curious fluctuations in her speech.

Vaso-motor Hypothesis of Hysterical Symptoms.

The hypothesis of a vaso-motor spasm or vaso-motor paresis as a basis for hysterical symptoms, which Dr. Bastian only suggests, is adopted without reserve by Dr. T. D. Savill. This author considers:[3] 1. That "hysteria consists of an instability or undue irritability of all the nervous and reflex centres throughout the body, and particularly those of the vaso-motor and sympathetic systems." 2. That "hysterical paralysis or tremor and many other hysterical phenomena hitherto unexplained are produced by vascular changes in the nervous system and elsewhere." The only mental process that he admits is that emotion, as a determining factor, may set in action the irritable vaso-motor machinery. "Given inherently unstable nerve centres and cells throughout the nervous system, emotion starts vaso-motor changes and thus disturbs the blood supply and the nutrition of other unstable centres sufficiently to produce in them an abeyance or an irritation of their functions."

Savill lays great stress on certain vascular phenomena which may be witnessed in the skin, such as general or partial blanching and patches of transient congestion, which he affirms are very frequent in hysteria, and, indeed, characteristic of it. He argues that similar processes may take place in the central nervous system, and that local flushing or ischæmia of nerve centres thus caused may bring about hysterical paralyses or other symptoms. For myself I do not agree that the skin symptoms mentioned by Savill are in any way characteristic of hysteria; and I think that there is no independent evidence of the supposed vaso-motor affections of the nervous system, and that even if they existed they would furnish a very poor explanation of the phenomena of hysteria. Nevertheless, we shall do well to remember that the mental state which we call emotion has a close connexion with our bodily states, and especially with the state of our vaso-motor apparatus; and further, that in the opinion of several authors (as I mentioned at the beginning of this lecture) emotion is an essential factor in the production of hysteria.

PSYCHOLOGICAL VIEWS.

You will have seen that both of these English authors approach the problem of hysteria from the physical or physiological side. We will now consider the opinions of two distinguished French authorities (I must limit myself to two) who take the other point of view. In dealing with the French literature I must acknowledge my obligations to my friend, Dr. Kinnier Wilson, both for his excellent article in *Brain* which I have just mentioned, and for other help.

---

[3] THE LANCET, 1907, vol. i., p. 1633.

THE VIEWS OF PROFESSOR BABINSKI.

Just as Dr. Bastian would curtail hysteria as viewed from the physical side, so would Professor Babinski curtail it as viewed from the psychical aspect.

Hysteria, according to Babinski,[4] is essentially a matter of suggestion. The symptoms arise in conformity with ideas that have been implanted in the patient's mind, and they can be removed by "persuasion," by which he appears to mean a counter-suggestion of a reasonable kind, calculated to restore the patient to a normal condition. The patient is not a malingerer, for she does not produce the symptoms consciously and of set purpose; nevertheless she does, unconsciously, produce them, and they are never of a kind which she could not produce voluntarily. There is simulation, but it is unconscious and involuntary simulation. How, then, does the patient come by the ideas to which the symptoms conform? And how does it come to pass that in so many patients we find, again and again, the same symptoms (i.e., the same ideas) recurring with such regularity that they have been called "stigmata"—that is, characteristic marks of a disease? Babinski's answer is that these stigmata are suggested by the physician as he examines the patient.

Suggestion as a Factor in Anæsthesia.

Say that a patient is being examined for hemianæsthesia; the touch first on one side of the body, and then on the other, accompanied by the question, "Do you feel that?" in each case is enough to make the patient suppose that she ought not to feel alike on the two sides of the body—and consequently she does not. And it is, as a fact, noteworthy that often before she was examined she did not know that she was hemianæsthetic. In his own practice, Babinski tells us, when the examination is so conducted that no such inference can be drawn from it by the patient, hysterical anæsthesia does not exist.

Now, I have no difficulty in believing that anæsthesia can be produced in this way; indeed, I remember a striking instance of it. There was a girl in Queen-square Hospital whose illness I had diagnosed as hysterical. My then clinical assistant was deeply interested in the study of the distribution of the sensory nerve roots. He told me one day, and demonstrated to me, that this patient was anæsthetic in the area of one of the cervical roots. This, I felt, was a blow to my diagnosis. Next week the anæsthesia had spread to the area of the adjacent nerve root. The following week, however, it had spread all over her body. So we settled down comfortably to the original diagnosis. The patient had somehow appropriated the anatomical knowledge of her examiner.

But that all, or even most, hysterical anæsthesia is produced by such suggestion I cannot admit. Other physicians are as careful as Babinski in their methods of examination, and yet they find anæsthesia in patients who have never been examined before. You will remember, Sir, the method described by Dr. Glynn in his Bradshaw lecture, in which no question is put to the patient at all. Sometimes, too, we find anæsthesia distributed in ways which we do not ourselves expect—for instance, in irregularly scattered patches. Lastly, it sometimes happens that the patient knows that she is anæsthetic before she comes to the physician. The following illustration of this is from Dr. Kinnier Wilson's paper; it is a case that I well remember, under the care of Dr. James Taylor at Queen-square Hospital. A woman, who had had exceptionally good health previously, developed hysterical symptoms after a fall. She discovered for herself before she came to the hospital and before she was examined by any doctor a numbness and loss of sensation on the right side. There was nothing in the manner of her fall to suggest to her an injury on this side, for she struck her back and her head and supposed that these were the parts injured.

I conclude, therefore, that suggestion by the physician is by no means the only way in which anæsthesia and the other stigmata are produced: I doubt, indeed, whether it is a usual way.

Other Symptoms and their Relation to Suggestion.

Then there are all sorts of other symptoms, which are evidently not suggested by the physician or friends, because they come as a complete surprise to them. These, we are told, may be the result of "auto-suggestion." Now, auto-suggestion is a word as convenient as "auto-intoxication," and about as unsatisfactory. The last part of it implies something coming from the outside; the first part "auto" implies that the preponderant factor is the working of the patient's own mind. Now this would take us back to the remembrance and to the mental elaboration of any previous experiences and any previous ideas—in short, to an explanation which may indeed be correct, but which comprehends far more than the "suggestion" with which we started.

There are further objections to making suggestibility the sole canon of hysteria. We all know people who are gullible enough who are not at all hysterical; and, on the other hand, many hysterical patients are not particularly open to persuasion, at any rate when you try to remove their symptoms that way, whether in hypnosis or out of it. And for the majority of them, granting the supposed susceptibility to suggestion, what causes this? It can hardly be a primary attribute of their minds; there must surely be something beyond it.

And what of such symptoms as œdema, congestion, hæmorrhage, and so-called trophic symptoms, which are so difficult to explain on any psychological theory? These at any rate are not such as the patient could produce by will, apart of course from self-mutilation. Some of them Babinski would class as secondary symptoms. Muscular atrophy, for instance, he considers to be secondary to disuse of the limb. With others he deals very summarily—namely, by denying their existence. They do not suit the theory and therefore they must go. This seems rather too drastic: Professor Babinski is, we know, a giant among neurologists, but he ought not to play the part of Procrustes.

THE VIEWS OF PROFESSOR JANET.

I must now turn to the views of Professor Pierre Janet. For the sake of brevity I am obliged to put them before you in a somewhat dogmatic form; but his method as I daresay you know, is not dogmatic or deductive, for his generalisations are built up on the results of close study of hysterical patients. Certain questions are involved here, of a psychological rather than a medical nature, such as the nature of our personal consciousness and of what is often called now subconsciousness.

---

[4] See principally Ma Conception de l'Hystérie et de l'Hypnotisme (Pithiatisme). Chartres. Imprimerie Durand. 1906.

On this subject Janet advances the following statements.

Consciousness and Subconsciousness.

From our earliest years our ideas—that is to say, mental phenomena or (more shortly) mental states of all kinds, whether they be sensations, volitions, memories, or emotions—have been grouping themselves together into a system in which they become bound together by innumerable ties of association. How or when this system originated we do not know, but the process of addition to it is always going on. Each time that a new mental state is brought into relation with this system we are aware of the fact, and this assimilation or synthesis of the new with the old constitutes a personal perception or act of consciousness.

But much goes on in our minds of which we are not conscious. An impression may be made on our bodily organs and the corresponding mental state arise, a memory may recur or an emotion stir within us, yet we may not realise the fact, because it has not reached the dominant system of our personal consciousness. Many instances will occur to you; thus of some things, such as the sensations from our internal viscera, we are hardly ever conscious, at least in health; other things may not reach our consciousness, because at the time it is busy with something else. In questioning a candidate for examination you might not hear the clock strike; in listening attentively to a lecture you might not notice how close the room was. Such trivial instances show at least that our consciousness has a limited range; it cannot take in an unlimited number of things at once, especially if one of them is particularly engrossing. Now the assumption may be made that this limitation of the range or "field" of consciousness differs in different individuals, that we have not all the same power of simultaneously taking into it a large number of mental states, and further, that in hysterical patients this power of synthesis is pre-eminently defective.

The importance of this last dictum will appear as we go on; meanwhile we may ask what happens to the mental states which never rise into the personal consciousness, but remain (as the phrase goes) subconscious. These too may combine into systems, separate from though analogous to the system of personality. The chance for such a combination to begin comes when our personal consciousness is at a low ebb, as may happen during the exhaustion of illness or anxiety, or during morbid reveries, or from the paralysing effect of a sudden emotion, such as terror, which has given us, so to speak, a knock-out blow; or perhaps because we are so constituted that our personal consciousness has naturally a feeble and noncomprehensive grasp—that is to say, because we are predisposed to hysteria. A vivid impression made upon us at such times becomes associated with other impressions of the moment and with appropriate memories of the past, and thus is originated an independent system of ideas withdrawn from our personal consciousness, a secondary consciousness. Under favourable circumstances this secondary system may grow until it interferes with the primary system or even threatens to usurp its place. The hysterical mind offers a favourable soil for such a growth, for the personal system cannot assimilate readily, and thus leaves the more material for parasitic systems to feed upon. The central government is weak and there results a turbulent home rule all round.

Varied Meanings given to Subconsciousness.

Perhaps I have gone too far in stating these things in the terms of a definite theory. I hasten to add that Professor Janet himself puts forward his views on subconscious phenomena less as a cut-and-dried explanation of facts than as a convenient way of summarising facts. In this he is certainly more moderate than others whose speculations on this subject have been inclined to run riot. For subconsciousness is fast becoming quite a popular word—most unfortunately, I think, for there is still much doubt what it ought to mean,[5] whether it means merely what Carpenter described as "unconscious cerebration," or whether the "subliminal consciousness" of Myers, a mental substratum possessed (as he thinks) not only by every man, but by all men in common, and indeed a part of the infinite mind, or whether the "unconscious" of Freud, that large dark chamber of our mind, the door of which is partly open at night to dreams, but mostly closed by day, until the psycho-analyst comes to call spirits from its vasty deep.

Again, the subconscious system of ideas, or secondary state of consciousness, has been elaborated into the conception of a dual, alternating personality like Dr. Jekyll and Mr. Hyde, or other more historical cases; or even multiple personalities, more than one of which may coexist in the same patient at the same time, as in the famous case of Miss Beauchamp described by Dr. Morton Prince[6]—I beg her pardon, I ought to say the Misses Beauchamp, for there were some four or five of her in the same body. Two of them had a simultaneous existence—namely, the original shy, prudish, neurotic Miss Beauchamp, and a certain rollicking girl called Sally, who knew all Miss Beauchamp's thoughts and doings, and chiefly employed herself in getting her into scrapes. Truly a remarkable psychological family, several people in one, including this oddly assorted pair of Siamese twins! To speculate on their personality makes one's head go round.

Mental "Stigmata."

But to return to hysteria. The fundamental defect, according to Janet, consists, it is true, in a feebleness of mental synthesis; yet this is a condition which has to be inferred and cannot be directly observed. But there are certain very common mental traits open to observation to which he gives the name of mental stigmata, adopting the term used by Charcot for certain common bodily symptoms. These I need only just mention, because I think you will not doubt their existence. Neither will I stop to show their connexions with the fundamental feebleness of synthesis; I will leave that to you. Now we may mention among such mental "stigmata":—

1. Suggestibility—not merely that an idea can be easily implanted in a patient's mind, but that it tends to develop there and engross the whole mind.

2. Distractibility. This is merely the obverse of suggestibility; while the patient is occupied with one idea she forgets all others.

3. Feebleness of will, so called "aboulia." Whatever "the will" means, it implies at the lowest estimate a weighing and comparison of many motives, which is just the sort of thing which the hysterical patient cannot do. Sir James Paget, I think, put it thus: It is not that the patient will not, but that she cannot will.

---

[5] See Subconscious Phenomena, by Münsterberg and others, Rebman, Limited.

[6] The Dissociation of a Personality.

4. Changeability and waywardness, as of symptoms, so of disposition and desires—a trait that has been most unjustly transferred to the whole female sex. "Varium et mutabile semper Femina" was the excuse the gods gave to Aeneas—when he deserted Dido! though it would have been more honest to say with the drunken sailor in the *Tempest*—

> Then to sea, boys, and let her go hang.

Amnesia.

But there is one mental peculiarity on which we must dwell longer—namely,

5. Defective memory—amnesia. In accordance with Janet's fundamental hypothesis, we should expect that a person who cannot gather up into his consciousness many things at once would have a bad memory. Nevertheless, loss of memory in the ordinary sense of the term—namely, a general forgetfulness of all events extending over a given time in the past—is not, I think, very familiar to us as a symptom of hysteria. Possibly that may be because, like anæsthesia, the symptom requires to be looked for. Thus a girl under my care in St. Bartholomew's Hospital gave us a fair history of her illness, but on questioning her more closely concerning the onset it was found that she had totally forgotten all the events of a fortnight or so at that period of her life. She filled up this gap apparently with what she had been told. Her mother, to whom we referred, knew all about the girl's peculiar loss of memory, but had not thought it worth mentioning. So in this case the symptom was found out almost by accident. Similarly the sister in charge of my then female ward at St. Bartholomew's Hospital told me not long ago that when hysterical patients who had been in the ward came back to visit her after their discharge, being apparently well, many of them did not remember anything about their illness nor what had happened to them in the ward, or at most had hazy memories about it, "like a dream." But Janet gives much more striking instances of this kind of amnesia, where a piece of the patient's life is clean cut out of remembrance.

But in addition to this localised amnesia there is a loss of memory which may be called "systematised." The patient forgets everything connected with a particular person, or a particular event, or even a particular conception. It is a class of memories that disappears, not a series of events in time. This is less strange than it seems at first sight, for our normal memory is a faculty which is given to specialising. One man remembers people by their faces, another by their voices. I knew a gentleman who had a wonderful memory for histories, poetry, languages, derivations of words, and so forth, but if he took a hand at whist he could hardly remember a card that had been played. Now what the hysterical patient is most apt to forget are the things connected with the causation of her symptoms. Thus Mrs. A (already mentioned in my first lecture), when she came to me for a contracture of her fingers, gave me an account from which one would have supposed that the contracture came on spontaneously, until her husband said, "Why, you have forgotten to tell the doctor about the dog that bit your hand." And this brings us to a sort of amnesia which we should all admit to exist—namely, that after a severe hysterical fit the patient, when she has come completely round, forgets all the circumstances, physical and mental, of the fit itself. But in all these cases of hysterical amnesia there is a fact which must be emphasised—namely, that the memories are not annihilated, they are simply in abeyance, and under appropriate circumstances can revive. Thus, if the patient's fits be of the dramatic or somnambulistic type, the drama, or at least its *leit-motif*, recurs in each attack. Or perhaps under hypnotism or by means of automatic handwriting the patient may be made to reveal the lost memories. So we may put it in this way—the memories have disappeared from the system of personal consciousness, and the patient cannot call them up at will, but they remain in the subconsciousness, attached probably to some independent system of ideas, in connexion with which they can automatically reappear.

Fixed Ideas.

After saying that hysterical patients are apt to be forgetful, changeable, and irresolute, it seems almost a contradiction to say that they are dominated by fixed ideas. So far from being a contradiction, however, it is almost a corollary of what has been already said. In speaking of a fixed idea we generally, I think, refer to the obsession of a psychasthenic patient. This is something actually present to his consciousness. He knows too well the feeling that he may have committed some crime, the fear that he may be suffering from some disease, the impulse to injure himself or others. As a set off, indeed, to the unwelcome presence of this idea, he generally retains some control over it, so that it rarely becomes completely realised, either in thought so as to become a delusion, or in action so as to become a crime. But the fixed idea of the hysterical patient is altogether subconscious. It is part of, indeed the nucleus of, a secondary system of consciousness. Thus, being out of relation to the system of personal consciousness, ignored, uncontrolled, and uncorrected by the patient and by the realities of her daily life, it is all the more likely to become fixed and to develop abnormally, both in precision of detail and in overpowering effect. You and I, perhaps, with our humdrum lives and phlegmatic temperaments, hardly recognise the picturesque and realistic power of a vivid idea. Yet you remember how the widowed Lady Constance describes the loss of her only son—

> Grief fills the room up of my absent child,
> Lies in his bed, walks up and down with me,
> Puts on his pretty looks, repeats his words,
> Remembers me of all his gracious parts,
> Stuffs out his vacant garments with his form—
> Then have I reason to be fond of grief.

So long as the fixed idea remains buried in the subconsciousness it may give rise to no overt trouble; but should circumstances arise to weaken the grasp of the personal consciousness, so that it vacates its proper dominion, then the subconscious idea may assume command. The result is a hysterical fit—that is, a somnambulism, or second state of consciousness, in which the patient passes out of relation to her real conditions, into an imaginary set of conditions dictated by the fixed idea or reminiscence of the past. As we do not often see in this country perfect specimens of hysterical somnambulism, I will quote one from Janet's writings.[1]

A girl had been alone in lodgings with her mother; she had nursed her day and night and worked in the intervals for her daily bread. When the mother died the daughter tried to restore the respirations, but the only results of her efforts were that the body fell from the bed and she had the utmost difficulty in replacing it. The girl's fits began some time after the funeral. In the fit she went through the scene of her mother's death, partly in word, partly in action, with all the terrible details; and when that was over began preparations for her own suicide by throwing herself under a train. She stretched herself on the floor of the ward and lay there half frightened, half impatient, waiting for the train to come. At last it came; her eyes dilated with terror, she gave a loud shriek, and then lay motionless as if dead. This fit might be repeated more than once, but when it was well over she picked up the work she had been doing and went on with it, totally unconcerned with what she had been through, because, indeed, she was now totally ignorant of it.

---

[1] Les Névroses, Paris, Flammarion, 1910.

In such a fit the sudden and complete development of the idea and the equally sudden and complete disappearance of it are in striking contrast with the persistent, conscious, but incompletely realised obsession of a psychasthenic patient.

Action of Subconscious Ideas.

But the subconscious fixed idea, without superseding the personal consciousness and without taking temporary control of the mind, may have other more permanent effects upon the patient. I have mentioned the theory that hysterical paralysis is due to an idea. This originally meant that the patient did not move because she thought she could not, or because some thought restrained her from moving. It was urged as an objection that patients denied the existence of any such thought. This difficulty disappears now, since we have learned that there are many thoughts in our minds of which we know nothing. In some cases the existence of such an unrecognised thought can be shown by the history, as when the paralysis can be traced back to some suggestive event, such as an injury, or a fright, or the sight of some stricken person. Or again, the symptom may follow directly upon a hysterical fit, so that we may suppose that some part of the idea, which was elaborated in the fit, survives when the fit has subsided. In the drama of suicide, just mentioned, if the imaginary train had gone over the patient's legs, it is quite likely that she might have remained paraplegic. In many cases, however, we can obtain no clue to the patient's fixed idea, unless we can make some direct appeal to the subconsciousness, by hypnotism or some similar means. But if you grant that a subconscious idea may act in the way described, then it is obvious that a large variety of hysterical symptoms may be explained in this way, not only paralyses, but also pains, spasmodic movements, and some peculiar contractures like those quoted in my first lecture.

There are other ways in which Janet's theories are adapted to the explanation of hysterical symptoms. Anæsthesia, for instance, can be referred at once to his fundamental conception of hysteria—namely, the inability to realise many ideas at the same time. Owing to this inability sensations, which may be at the same time unimportant for the patient to realise, are allowed to drop out of her personal consciousness, and fail again to find a place in it. We can understand the peculiarities of hysterical anæsthesia when we consider it from this point of view; how it is that the patient is unaware of her anæsthesia, how it is that she can still feel, though she does not recognise that she feels, and finally the distribution of the anæsthesia, which does not correspond to anatomy, but to the anatomical ideas of the man in the street about a hand or a wrist, an arm, or other parts. Though of course if a functional anæsthesia befell some member of my audience whose anatomical conceptions are correct, and who think in terms of Dr. Head's diagrams, its distribution might possibly be different.

Hemianæsthesia, limited by the middle line, has always seemed to me a little curious regarded in this light. I suppose Janet's explanation is that we think of ourselves as made up of two halves, right and left. I wonder if we really do. An observation by Dr. Foster Kennedy, quoted by Dr. Kinnier Wilson,[8] seems to point that way. Dr. Kennedy, while going his rounds as house physician at Queen-square Hospital, found a woman who had hysterical hemianæsthesia of the left side, with her right arm so placed that her right (sound) hand was well to the left side of her body. It occurred to him to test the sensation of the right hand while it was in this position, and he found it was anæsthetic, which it had not been before.

The Psychological Representation of a Function.

Anæsthesia has been advanced as an explanation of diverse other hysterical symptoms—for instance, it has been said that retention of urine is due to anæsthesia of the bladder, and anorexia nervosa to anæsthesia of the stomach. But of many things of this kind Janet takes a much more general view which is based on his idea of that which we roughly call a function. This idea I must try to put before you, in concluding this lecture.

I suppose that by "function" we generally mean a combination of bodily events, so that they work harmoniously together towards some given physiological end. In some of these combinations the organisation is complete and fixed almost from our birth, like that of the circulation, over which we have little, if any, personal control. Over others, like that of micturition, a certain amount of control is still exercised. In others, like that of walking, we can watch the gradual change from conscious effort to something like automatism. It is worth noting, however, that even when practice has made a function perfect, it is still liable to be upset by unusual mental conditions. A person who can walk without thinking along a country road, or even saunter through the traffic of a big thoroughfare, might be unable to walk in a State procession down the nave of Westminster Abbey, because, as we say, he is "nervous."

The combinations necessary for the performance of a function are made in the central nervous system, and in the case of the lower, most completely organised, functions we know the groups of cells and fibres, the so-called centres, which chiefly preside over the function. We know something of the anatomy of even such a high function as that of speech, and we imagine that similarly for the very highest functions there must be some anatomical arrangements in course of formation, though we must own we do not know. Now Janet holds that for the due performance of a function an organisation, comparable to this bodily organisation, must have been made in the mind. Just as simple sensations and memories are built up to form the idea of an object or of a movement, so a far more complicated system of ideas and memories is built up to form the psychological representation of a function.

---

[8] Brain, vol. xxxiii., pp. 334, 345.

Perhaps you will think this rather too transcendental, and will find in it only the desire to escape, as many desire to escape, from the thraldom of our vile body, as in the Ideas of Plato, and the bodies celestial of the Apostle Paul. But no denial is made of physical organisation within the brain; it is merely asserted that in the present state of our knowledge it is more profitable to study the psychological aspect.

Exercise of Function in the Hysterical.

Let us assume that combinations or systems of ideas exist in our minds, which represent functions. These in the normal mind must be in touch with and under the control of that large system of ideas which we have called our personal consciousness. But in the hysterical mind this is evidently just the proviso that may fail, because the unifying personal element is feeble. The bodily conditions necessary for the exercise of a function may be perfect, the psychological organisation, also necessary for it, may exist, but this latter may have dropped away from the personal consciousness. Two possibilities may then arise: either the patient may be utterly unable to exercise the function voluntarily and consciously, or else the function may exercise itself automatically and without control. I will take but one illustration—namely, the function of speech.

1. "Functional paralysis" of speech, in an incomplete form, is seen in hysterical aphonia, hysterical stammering, and possibly in other varieties of speech affection. In a complete form it is seen in hysterical mutism or dumbness. Yet in such cases the organisations necessary for speech, whether bodily or mental, must be intact, for the patient may find her voice under the surprise of an electric shock or perhaps will talk in her sleep, and in any case we know full well that some day she will speak quite well.

2. The other condition—viz., uncontrollable speech—is not, I must own, very familiar to me. But Janet has seen many examples of what he calls hysterical logorrhœa, in which the patient pours forth, for hours together, floods of conversation, generally of a disconnected kind and forgotten as soon as uttered. The only illustration I could myself give was not a case of pure hysteria, for the lady who was the subject of it became insane. All her friends knew that an attack was coming on when once she began to talk; soon the talking became incessant, and delusions became intermingled with it. One delusion was that she was the recording angel, and the things that she recorded, in a loud voice, were extremely embarrassing to many of her friends.

Now, whether you grant the existence of psychological equivalents of functions, or whether you think the conception too vague and elastic, still you will admit that such an idea may help to give some definiteness to our notion of a "functional disease" which hitherto has been based simply on negative characteristics.

I hope, Sir, that I have not wearied you out with this discussion on theories, and I hope that in trying to put them into the compass of one lecture I may not have seriously obscured the authors' meaning.

In the next lecture I propose to consider Professor Freud's doctrines about hysteria, and since that will involve the discussion of certain disagreeable topics I must ask you your pardon in advance.

THE DIAGNOSIS OF POST-PYLORIC (DUODENAL) ULCER

BY MEANS OF SERIAL RADIOGRAPHY.

BY LEWIS GREGORY COLE, M.D.,
PROFESSOR OF ROENTGENOLOGY TO CORNELL UNIVERSITY MEDICAL COLLEGE.

IN previous communications[1] evidence has been assembled to show that the portion of the gastro-intestinal tract, previously called the first or ascending portion of the duodenum, pars superior horizontalis, or "bulbus duodeni," is not part of the duodenum, but really belongs to the stomach, and the name "pilleus ventriculi" (cap of the stomach) has been applied to it. Therefore the term post-pyloric ulcer, or ulcer of the cap, should be substituted for "duodenal ulcer," and will be used herein except in quotations. The diagnosis of post-pyloric ulcer and its differentiation from and relation to malignant and non-malignant lesions of the stomach form one of the firing lines of surgical advance. The importance of this field of work is evidenced by the communications of Wier, Moynihan, Codman, Mayo, and others, who have adequately described the clinical and surgical aspects of the subject.

Considering the part that radiology has played in medical and surgical diagnosis, it is appropriate that serial radiography should be an active scout in the detection of ulcers of the cap. Communications having a direct or indirect bearing on the radiographic diagnosis of gastric and duodenal ulcers have been published by Hemmeter, Holzknecht, Schwartz, Ashbury, Haudek, Strauss, Kreuzfuch, and Pfahler. Two diagnostic methods have been employed. One is based on symptom-complices, or groups of clinical manifestations, some of which are recognised by fluoroscopy or radiography. But they are symptoms only, as the name suggests, and not direct evidence of the lesion. The other method depends on the contention that bismuth will adhere to the surface of an ulcer or lodge in its crater. Failure to differentiate such flecks from retention in the normal cap is the weak point in this theory. Haudek's "niche" is a finding of undoubted significance. But it very frequently occurs in extensive inoperable carcinoma of the lesser curvature, and furthermore must be carefully differentiated from a small deposit in a pouch of the œsophagus near the cardia.

Strauss's excellent article on duodenal ulcer[2] covers many of my observations, some of which have been published, but certain of his deductions do not correspond with my interpretation of the phenomena presented.[3] He bases the diagnosis of ulcer on a rather elaborate symptom-complex which he has compiled. Strauss's remark that roentgen-kinematography may sometimes prove of great diagnostic assistance brings me to the crux of my communication.

The technique of serial radiography, and especially the relative value of serial radiography and roentgen-kinematography, have been fully explained heretofore. The gist of it is that 24 instantaneous radiographs of different phases of different cycles, made in rapid succession, are of more diagnostic value than 24 radiographs of different phases of one

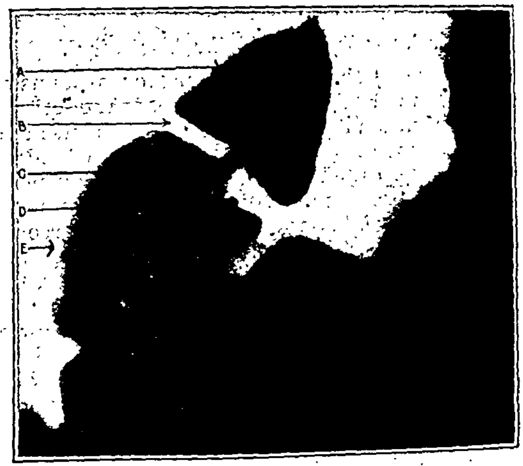
cycle. Technique aside, we pass at once to a description of the anatomy and physiology of the pars pylorica, pyloric sphincter, and pilleus ventriculi as observed by means of serial radiography. This subject was fully discussed before the American Medical Association in a paper which is now at press.[4]

The progression of the gastric peristalsis observed by Cannon in the cat[5] was demonstrated in man by Kaestle, Rieder, and Rosenthal.[6] While the progress of the peristalsis may be seen in nearly all cases, the speaker recognised and has previously described a much more complicated gastric motor phenomenon, which, like the heart action, takes place in cycles, marked by a systole and diastole, or a contraction and relaxation of all the peristaltic waves simultaneously. A cycle exists during the time occupied by the formation of each terminal wave or antrum. During the stage of systole (Fig. 3A), which consumes about seven-tenths of the gastric cycle,

FIG. 2.



Normal cap. A, Cap. B, Sphincter. C, Lumen of sphincter. D, Congenital fold. E, Terminal wave.

chyme is expelled through the lumen of the pyloric sphincter into the pilleus ventriculi. The remaining three-tenths of the cycle are consumed by diastole (Fig. 3B) when the pyloric sphincter closes and prevents the chyme in the cap from dropping back into the stomach. Sometimes the chyme in the stomach drops away from the pyloric sphincter.

The Physiology of the Pylorus, Pilleum Ventriculi, and Duodenum was discussed in a paper before the American Medical Association, June, 1913.[7] There is no evidence of a periodical opening and closing of the pyloric sphincter independent of the gastric cycle.

The radiographic evidence that all the characteristics of the cap are gastric rather than duodenal is corroborated by embryology, anatomy, physiology, histology, and surgery. The cap (Figs. 1, 2, 3A and B) corresponds in

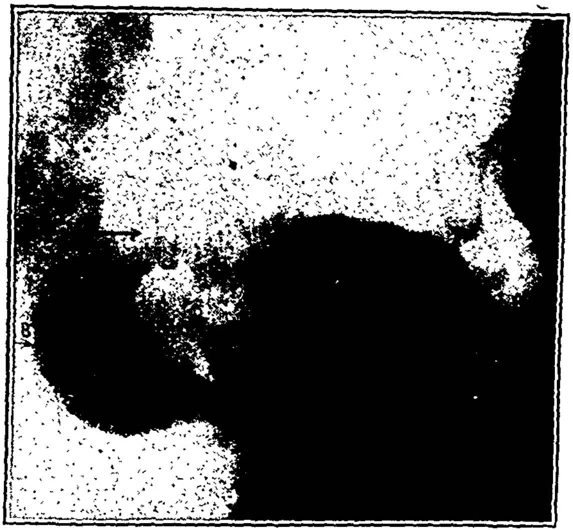
ulcer, in which a localised area of the muscular coat has been destroyed and replaced by non-elastic connective tissue. Codman acknowledges that such areas are difficult to detect at operation or necropsy, even when a surgeon is looking for them, and I think that these areas correspond with the lesion described by Bloodgood as non-ulcerative lesions in this region. The frequency with which they are recognised radiographically corroborates Codman's contention that ulcers of the cap occur much more frequently than one suspects. And it also indicates the frequency with which ulcers heal without surgical interference. The clinical history must be considered in determining whether these slight, constant deformities are sufficiently extensive to require surgical interference or even to be observed surgically, especially if the surgeon is adverse to the diagnosis of post-pyloric ulcer, and is looking for an appendix, Lane's kink, or something else.

FIG. 16.



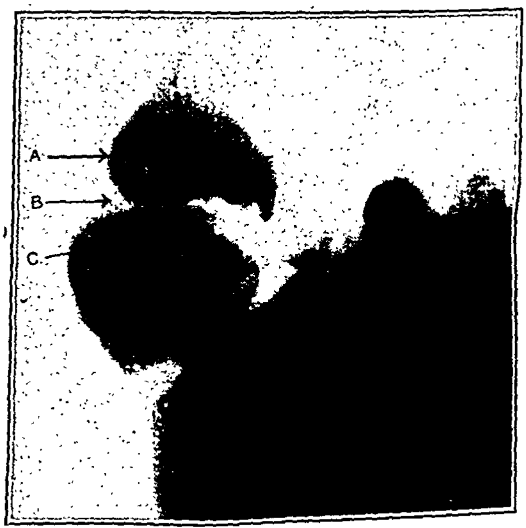
Ulcer with cicatricial contraction and pyloric obstruction.
A, Destruction of cap. B, Terminal wave.

A spasm of the cap, associated with appendicitis, Lane's kink, renal calculi or gall-stones, resembles the distortion from post-pyloric ulcer, except that the spasm varies in appearance, and is absent in one or more of the 40 or 50 radiographs of the series. It can usually be completely relieved by administering belladonna before the confirmatory examination, with the result that a normal cap and sphincter presents. Such functional disturbances must be carefully differentiated from organic lesions of the cap. If one radiograph out of 50 shows a perfectly symmetrical cap, and a normal pyloric sphincter, a negative diagnosis of post-pyloric ulcer is justified.

A positive differentiation between post-pyloric ulcer and adhesions of the cap from gall-bladder infection cannot always be made exclusively from the radiographic findings. Gall-bladder infection usually presents a more extensive involvement of the pylorus and cap. It may involve the greater curvature and draw the stomach to the right, causing an angulation of the cap. The cap may be involved in the adhesions, but not more so than the pyloric end of the stomach, and there is no evidence of a localised area of induration of the cap, nor is obstruction of its lumen so frequent. This differential diagnosis between post-pyloric ulcer and gall-bladder infection is of more scientific interest than practical value, because in either of the conditions surgery is indicated, if the lesion sufficiently extensive and associated with sympton

Adhesions from post-pyloric ulcer may invol other organs, the hepatic flexure of the colon, t stomach or the duodeno-jejunal junction, where t lower end of the C-shaped duodenum lies in clo proximity to the cap. Sometimes the symptoms adhesions of the colon are more marked than tho of the ulcer itself, and lead to a radiograpl examination of the colon rather than of the stomac It is therefore wise in all cases of adhesions of t hepatic flexure and first portion of the transver colon to make a radiographic examination of t stomach and duodenum. When adhesions from ulcer of the cap involve and obstruct the lower e of the C-shaped duodenum, there is an unusu dilatation of the descending and horizontal portion causing the sausage-shaped duodenum, referred to Holzknecht. This sausage-shaped appearance not necessarily an indication [of ulcer of the ca as it is more likely to present in cases of chron obstruction of the duodenum by the root of th mesentery, a condition described by Codman. Th same obstruction at the duodeno-jejunal junctio may also be caused by ulcers on the posterior wal of the stomach.

FIG. 17.



Small ulcer of sphincter. A, Cap. B, Sphincter. C, Small ulcer.

By the use of serial radiography, previousl described by the present author, George (Boston has been able to diagnose post-pyloric ulcers with a degree of certainty equal to that of the work herein reported. The procedure may seem very elaborate and therefore expensive, but considering the obscurity of these lesions, and the fact that the negative or positive diagnosis of post-pyloric ulcer by serial radiography is equally as accurate as the radiographic diagnosis of renal or ureteral calculus, one is justified in expending an unlimited amount of energy in detecting this lesion and differentiating it from other lesions.

This article has dealt solely with the *method* of diagnosing post-pyloric ulcer, and with one or two exceptions all of the cases illustrated have been proven by surgical procedure. Lack of space has necessitated the omission of many other proven cases of equal interest.

New York.

ACUTE LOBAR COLLAPSE OF THE LUNG.

BY H. L. TIDY, M.D. OXON., M.R.C.P. LOND.,
PHYSICIAN TO POPLAR AND GREAT NORTHERN CENTRAL HOSPITALS;

AND

E. PHILLIPS, M.B. DURH., M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE PHYSICIAN TO POPLAR HOSPITAL.

THE following case has recently been under our observation at Poplar Hospital.

The patient, a man aged 29 years, was admitted on Feb. 4th, 1914. He was quite well until two days previously, when he had suddenly felt a pain in the right side of the chest. This was followed by cough, sweating, vomiting, and several shivering fits. These symptoms continued until Feb. 4th, when he was seen by a medical practitioner for the first time and sent to hospital. His previous health had been perfect.

On admission the patient complained of pain in the right side, especially over the sixth and seventh ribs in the axillary line. His face was slightly cyanosed and the alæ nasi were working. There was a frequent restrained cough. The temperature was 103° F., the pulse was 104, and the respirations were 40. The sputum was scanty, thin, and contained no blood. On examination on the right side the movement of the thorax was seen to be very slight. The percussion note was impaired. The air entry was poor and the breath sounds were faint. No tubular breathing was heard. A few fine crepitations were present at the site of the pain but not elsewhere. The vocal resonance was increased but not altered in character. The cardiac dulness was entirely to the right of the mid-sternal line. The apex beat was not visible or palpable. The heart sounds were audible only in the epigastrium. On the left side of the chest the air entry was increased, but otherwise the lung was normal. The liver and spleen were not palpable. The temperature fell gradually and the pulse became slower, but the respirations remained rapid.

When seen on Feb. 11th the temperature was normal, but the respiration was very rapid. Cough was infrequent. Pain was slight, and there was no superficial tenderness. There was slight cyanosis. The sputum was very scanty and contained no blood. No tubercle bacilli were found in the sputum. The right side of the thorax moved very slightly, except at the apex. The percussion note was definitely impaired, but not absolutely dull. The note was resonant to the left of the right border of the sternum. The air entry was very slight, and the breath sounds very faint, except at the apex. No tubular breathing and no crepitations or friction sounds were present. There was no whispering pectoriloquy or ægophony, but the vocal resonance and tactile fremitus were both increased on the right side. The cardiac dulness could be definitely recognised and separated from the right lung. At the level of the fourth rib it extended from the mid-sternal line to 3 inches to the right. The apex beat was not palpable, and the heart sounds were audible only in the epigastrium. In the mid-axillary line the liver dulness reached to the upper border of the fifth rib. On the left side the breath sounds were loud, but otherwise normal. There were no signs of pneumothorax. Traube's area of stomach resonance was somewhat large. On measurement the two halves of the thorax were both 18½ inches at the end of expiration. These measurements were the same on all subsequent occasions. The intercostal spaces on the right side showed no abnormality. The abdominal movements on the right side were diminished; otherwise there was nothing abnormal to be found in the abdomen. The nervous system was normal and there was no sign of paralysis. There was no clubbing of the fingers. No glands were palpable.

From that time the patient gradually improved. The respiration became slower, and the abnormal physical signs gradually disappeared. The percussion note on the right side became more resonant, while the vocal resonance and tactile vocal fremitus diminished, and the respiratory movements became greater. No moist sounds were heard. The sputum, always scanty, became less and soon disappeared. The heart meanwhile moved towards its normal position. The following table gives the measurements of the cardiac dulness from the mid-sternal line at various dates:—

	Right.	Left.
Feb. 11th	3 inches.	0
„ 18th	1¾ „	1¼ inches.
„ 24th	1¾ „	1¼ „
March 7th	1½ „	2 „
„ 14th	1¼ „	2½ „
„ 21st	Right border of sternum	3½ „

The pulse was regular throughout and no cardiac murmurs were present. The heart sounds gradually became audible over the area of cardiac dulness. The apex beat was just palpable when the patient left hospital. He felt perfectly well at the beginning of March, but the pulse and respiration remained more rapid than normal, and on his discharge were 80 and 24 respectively. In the lungs the abnormality which persisted longest was the increased vocal resonance on the right side. The physical signs were normal on March 21st.

The patient was radiographed on March 18th at the London Hospital by Dr. S. Gilbert Scott, who reported that the diaphragm was moving well, the heart being normal in size and position, the aorta normal and the apices of the lungs clear, and that no enlarged glands were present. The patient was discharged on March 23rd.

Diagnosis.—In view of the position of the heart and the physical signs in the lungs, the diagnosis of the pulmonary condition lay between fibroid lung and acute lobar collapse. The measurements of the two sides and the absence of previous ill-health excluded the presence of a fibroid lung, and the diagnosis of acute lobar collapse was made.

Apart from pneumothorax, acute lobar collapse may be considered to follow two conditions: (1) blockage of the air passages, and (2) inhibition or paralysis of the muscles of respiration.

Blockage of the air passages may result from various causes, such as a foreign body, plastic bronchitis, plugs of mucus, and pressure from neoplasms and aneurysms. The patient denied the possibility of a foreign body. There was nothing to suggest neoplasm or aneurysm. The physical signs did not point to the presence of bronchitis. No plugs of fibrin were coughed up as in plastic bronchitis.

With regard to inaction of the muscles of respiration, paralysis of the diaphragm may result from various conditions of the nervous system, such as diphtheritic neuritis or myasthenia gravis. Paralysis of the diaphragm would not account for the present case, since when the diaphragm is paralysed without the other muscles of respiration the lower ribs expand more than normally during respiration. The cause for this is referred to below. In the present case the ribs and the abdomen in the neighbourhood moved less than on the sound side. It appeared that the muscles of respiration had been reflexly inhibited. There was no abdominal cause to lead to this, and the apex of the lung was less affected than the base. The diagnosis was therefore made that as the result of pleurisy at the right base the muscles of respiration on that side had been inhibited, and this had been followed by acute lobar collapse of the lung.

The Occurrence of Acute Lobar Collapse.

Any foreign body which occupies space within the thorax must cause a certain degree of collapse of the lung. Such foreign bodies may be a pleural effusion, a pneumothorax, a neoplasm, or a gross enlargement of the heart, aorta, or pericardium. Of these, pneumothorax alone can cause sudden collapse, and must of necessity do so. Lobular collapse occurs in broncho-pneumonia, and may be extensive when the cause is widespread. Apart from these circumstances, a true acute lobar in fact, for delicacy of sensation, may be compared with the sensation at the tip of the tongue. But the sensation at the anal orifice is not only tactile. There are two senses: one is tactile, produced by contact of the contents of the bowel with the mucous membrane of the anal canal, and the other is the muscle sense, which may be described as the sensation caused by the stretching action of the muscle due to something within its grip. The sensitive area is practically confined to the anal canal proper; from an inch to an inch and a half above the anal orifice the mucous membrane is hardly at all sensitive except to distension of the rectal lumen.

The operation for piles of necessity implies interference with this sensitive area. Now, almost all the sensations at the anal orifice have for their immediate object some alteration in the state and degree of contraction of the sphincter muscle, and the action of this muscle is almost entirely reflex in character. It is therefore easy to understand why operations in this area are liable to result in pain, since the wounds cause constant irritation of this reflex, with consequent spasm and painful contraction of the muscle. Realising this, and influenced by the teaching of Hilton, surgeons attempted to prevent post-operative pain by stretching this muscle and so causing temporary paralysis. This was not successful, however, because, in the first place, unless the muscle is actually damaged paralysis is too transient—not lasting more than 30 minutes in most cases, and often not as long—and also because the muscle in the process of recovering its powers of contraction contracts spasmodically, causing sudden violent pain each time one of these contractions occurs.

The relief of pain by opium and morphia, while preferable to allowing the patient to suffer, is not satisfactory. To be of any real use it must be administered at frequent intervals for several days. Even then it will have the effect of making the patient feel ill and uncomfortable, and often of rendering him quite miserable. How, then, can we best prevent pain after this operation? The answer is that pain can be prevented by applying the same principles that have enabled surgeons to avoid pain resulting from operation wounds in other parts of the body. We have found that if a wound is made with no bruising or tearing of the tissues, under aseptic conditions, through clean tissues, and is kept aseptic and at rest, pain, except of a very slight and transient character, does not result. The anal region is no exception to this rule, and, given the same conditions, after-pain will be equally absent from operations in this region. Many surgeons, however, have assumed that an operation for piles cannot be carried out under aseptic conditions owing to its involving the rectum, and have therefore been content to perform this operation under conditions which they know are not aseptic, in that the tissues are not aseptically clean, or that contamination of the wound during or immediately after the operation is almost certain to take place. By a little alteration of the technique of the operation the conditions usually obtained for other operations can be secured when operating for piles. Very careful attention to the details of aseptic technique must, however, be observed in order to obtain success. The patient must be so prepared for operation that the rectum is quite empty and will remain so for some days. This is essential. The rectum and the whole of the field of operation must be thoroughly washed out with soap and water, and afterwards with a suitable antiseptic, until the surgeon is satisfied that the area of operation is surgically clean. The sphincter should not be stretched or damaged in any way, and the patient must therefore be thoroughly and deeply anæsthetised, or the sphincter will be in a condition of spasm which will render it impossible for the surgeon to reach the piles properly. The operation must be carried out with as little damage to the tissues as possible. By this I mean that pressure forceps should not be applied to tissues which are not going to be removed, that the mucous membrane or skin at the anal margin must not be included in ligatures, and that the number of ligatures applied for the control of hæmorrhage must be reduced to the smallest possible number. After the completion of the operation the wound must be bathed with some suitable antiseptic, the best, in my opinion, being 1 in 40 carbolic. Lastly, some form of dressing must be applied which will prevent infection of the wound. For this purpose I have found sterilised vaseline to be the best, and the lower part of the rectum may be filled with this.

For the last ten years I have been operating for piles on these lines, using the ligature operation in all but a few special cases, and I have found that post-operative pain is not more severe or frequent than after operations for hernia or varicose veins. Morphia is not required except as a hypnotic or to prevent the bowels from acting, and in the great majority of cases there is no pain of any consequence after the operation. Of course, it occasionally happens that the aseptic technique breaks down and infection of the wound occurs, with the result that post-operative pain requiring the use of morphia follows; but with increasing experience I have found that these cases have become less and less frequent, and most of the failures have been due to the fact that the preparation of the patient to ensure the bowels being empty has not been sufficiently carefully carried out. Pain after this operation, instead of being the rule, has become quite the exception.

Pain when the bowels act for the first time is avoidable with care and good nursing. With a skilled nurse pain after an action of the bowels is the exception. There is nothing to be gained by keeping the bowels confined for more than three or four days, as by that time the wounds in the anal canal have commenced to granulate and infection will not result in pain. After this a mild aperient daily is all that is necessary. I never allow the interior of the bowel to be interfered with in any way until all the ligatures have separated, except by the administration of a small injection of oil into the bowel daily to assist smooth action and protect the surface of the wounds.

I think it is better not to interfere with the patient's diet in any way, and instead of putting the patient on a slop diet after operation I allow an ordinary diet, but the amount of this is somewhat diminished until the bowels have been opened. I find patients are far less likely to get indigestion or discomfort, and the bowels are more easily relieved when the diet is not altered. Suddenly to put a healthy man on a diet of milk is quite sufficient to give him indigestion without the added factor of an operation and confinement to bed.

It is obviously difficult to obtain reliable statistics on such a subject as post-operative pain, but the following figures may, I think, be taken as approximately correct. They show the result of the last 200 consecutive cases of piles from my private case-books. All the cases in the series have been in private nursing homes, and the after-treatment has been carried out under my own personal supervision. Of the 200 cases 143 were men and 57 women. Of the total number only 28 (14 per cent.) complained of pain after the operation sufficiently severe to require an injection of morphia; and in only 8 cases (4 per cent.) was the pain bad enough to require more than one injection of morphia. In all the remaining cases pain was altogether absent or was relieved by 10 grains of aspirin, or by some simple measure such as a hot-water bottle.

I think these figures will compare very favourably with those for post-operative pain after any operation other than that for piles, and they show that there is no necessity for any special liability to pain after the operation for piles. These figures refer only to the ligature operation, cases treated by the cautery or Whitehead's operation having been excluded.

I have not worked out the figures for my cases treated in hospital during the same period, but I think the proportion of cases having pain is somewhat higher. It is difficult to obtain reliable figures in hospital practice owing to the fact that the house surgeon is constantly being changed, and while one can be depended on to keep the notes accurately in this respect another cannot. It must also be remembered that the same amount of individual attention cannot be given to hospital patients that is given to patients in private homes. Even in my hospital patients, however, it is quite the exception for morphia to be required after an operation for piles.

Hyde Park-place, W.

THE EARLY DETECTION OF DIABETES BY A SIMPLE METHOD OF ESTIMATION OF THE BLOOD SUGAR.

BY DR. OSCAR-KRAUS,
CARLSBAD.

SINCE urinalsis has become a usual method of investigation cases have been frequent in which different symptoms seem to point to the diagnosis of diabetes, and yet the urine does not show any trace of sugar. It is commonly said that when the amount of the sugar normally contained in the blood or, as it is called, the "sugar level," rises, by degrees the filtering apparatus of the kidney becomes permeable and the sugar passes into the urine. Consequently there must be a previous period in which, although there is not as yet any sugar in the urine, still there must be a greater amount than is normal in the blood.

Unfortunately estimation of the blood sugar has not hitherto been easy of performance on account of the great discomfort connected with the methods by which blood was obtained—namely, either by bleeding or by venepuncture. But in November, 1912, Max Adler and myself[1] published a new method by which it is rendered possible to obtain 15 drops of blood by a simple needle prick in the finger, and with this quantity to make an accurate estimation of the sugar contained in the blood. We originally performed the titration by using Fehling's solution very highly diluted, i.e., 1:10, and obtained good results. But as the method presented certain difficulties, especially for less trained operators, I substituted a new method of titration which permits the end of the reduction to be readily observed.

The analysis of blood sugar is carried out in the following manner. The pulp of the middle finger is thoroughly cleansed with ether and alcohol and a prick made with a Francke's needle, and about 15 drops of blood are dripped into a special small glass receptacle. The latter has a mark roughly indicating 1 c.c. and a second indicating 2 c.c. There must always be an excess of 1 c.c. of blood. Then by means of a capillary pipette 1 c.c. is measured into a small beaker and the pipette washed out with very little distilled water.

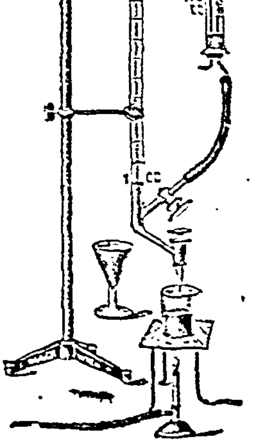
The sugar estimation consists of two parts:—

(*a*) *The dealbuminisation.*—This is carried out according to Max Adler's modification of Michaelis' and Rona's method. The liquid in the beaker is cautiously heated, whilst stirring it up, until it begins to turn turbid. Then 4–5 drops of 10 per cent. ferrum oxydatum dialysatum duplex (Merck) are added, and subsequently a few drops of a saturated watery solution of potassium sulphate, with constant soft boiling and stirring. All of a sudden the albumin will accumulate on the surface, while the liquid beneath will become absolutely clear. It is then very easy to separate the clear liquid from the albumin by filtering it into another small beaker and washing twice with hot distilled water. This liquid will hold all the sugar contained in 1 c.c. of blood.

(*b*) *The titration.*

I. *Preparation of the Standard Solutions.*

1. *Copper standard solution.*—2 grm. of sulphate of copper are exactly weighed and dissolved in about 100 c.c. of water and cooled down. Then 400 grm. of sulphocyanate of potassium, 12 grm. of ignited carbonate of sodium, and 24 grm. of citrate of sodium are dissolved with the aid of heat in about 600 c.c. of distilled water and filtered. It is then cooled down and the copper solution added by slowly pouring it into the other solution with constant stirring. 5 c.c. of a solution of 5 per cent. of ferrocyanide of potassium are now added and the whole is diluted with distilled water to exactly 1000 c.c. This solution, as compared with Fehling's solution, has the great advantage that it consists of a single liquid and keeps unaltered.



Special capillary burette for the estimation of blood sugar.

2. *Sugar standard solution.*—0·165 grm. of pure glucose is dissolved in a flask that holds 100 c.c. and is provided with a mark. Then a double tube is inserted and the bottle, neck downwards, is put into communication with a special burette by means of a rubber tube (see illustration). This burette holds 1 c.c. divided into 100 subdivisions.

II. *Testing the Standard Solutions.*

25 c.c. of the cuprous solution, with 25 additional c.c. of distilled water, are measured into a beaker and heated; then the sugar solution, still boiling,

---

[1] Zur Bestimmung des Blutzuckers, Berliner Klinische Wochenschrift, Nov. 18th, 1912, No. 47.

is poured into the beaker, at first rapidly, finally drop by drop. We generally use 3·35–3·36 c.c. to reduce 25 c.c. of the cuprous solution. The reaction is complete when the colour changes from light blue to faint canary. By a special device a second, third, and fourth c.c. can subsequently easily be passed from the flask into the burette without removing the latter from the flame. This result will hold good for a long time, because the sugar solution will not be easily altered, provided a small crystal of thymol is added. The *titration of the* blood sugar takes place on the same principle. 25 c.c. of the standard solution are added to the blood filtrate and heated, and the end point will be obtained by addition of the sugar solution. The difference between the result of the test titration and the amount of sugar solution that it was necessary to add to the blood filtrate, when *multiplied* by 0·165, gives the percentage of sugar in the blood.

There has been lately a tendency in the German literature of the subject to differentiate between the sugar content of the blood cells and that of the serum. But the results of the researches of the different authors with regard to this point differ so much that we have been *justified* hitherto *in* neglecting this question, the more so as for practical purposes only the figures of the total blood-sugar content are of importance. There is still another question worthy of a careful study—namely, that of "rest-reduction," as it is called in the German literature. It is most interesting *to know which reducing substances contained in* the blood are liable to fermentation and which are not. We hope to be able to publish the result of our investigations concerning this matter later on. Our first care after having worked out the above method[2] was to compare it with old methods, which would work only with larger quantities of blood, and we found that *it* worked with absolute accuracy.[3] These comparisons having given satisfactory results, we endeavoured to find out what were the figures of the blood-sugar content, while the stomach is empty, in individuals whose carbohydrate metabolism was normal. The following 25 cases from our practice show that the upper limit is at 0·114, the lower at 0·078, while the mean is at 0·09 per cent. We do not think that either the different authors or we ourselves have hitherto had a sufficient number of observations to allow of the estimation of an average figure, which should not be a merely fortuitous one. *Only with a very* big number are average figures trustworthy.

I will now show the way by which this estimation of the blood-sugar content can be utilised in determining the tolerance in diabetics. The following case is a very good example.

The patient, a diabetic, called on May 17th, 1913, when his urine was found to be *free from sugar*, but, on the other hand, the blood test showed an excess of sugar—namely, 0·163 per cent. before breakfast. He was put on the Carlsbad cure with appropriate diet. 27th: The figure was 0·086 per cent. before breakfast, a normal amount. Accordingly, on June 2nd 50 grammes of white bread were allowed for breakfast, the same quantity for lunch, and the blood was tested two hours after lunch. It showed a figure of 0·12 per cent., still a little too high, and therefore the total amount of bread was reduced to 60 grammes (30 for each meal) on June 4th, when the figure was 0·087 per cent. The next day 80 grammes were permitted, with a resulting figure of 0·10 per cent. Consequently the optimum of tolerance for white bread lay at about 70 grammes, corresponding to 40 grammes of carbohydrates according to *Schwenkenbecher's table of foods.*[4]

The above case is, from various points of view, very *instructive and demonstrative. It shows, first,* that a diabetic may have too much sugar in his system, even when he has none in the urine. His "internal tolerance" is not yet up to the assimilation of any amount of carbohydrates. It would therefore be a great mistake to stop the antidiabetic treatment (special diet included) until the blood test shows normal figures before the first meal in the morning. Then only is the patient fit for tolerance tests with measured quantities of carbohydrates. We always try white bread, because it is the very thing the patient craves for, and we administer it at the *first two meals, just as it is* taken in practice. Patients generally can dispense with taking bread in the evening. If the allowance is too high we reduce it, and *vice versâ*. Once the proper quantity is known it is a very simple thing to substitute other sources of carbohydrates, such as cereals, soups, fruit, and so forth, for the whole or part of the bread allowance, and thus to vary the *menu*.[5] Patients are but too thankful to know what they are entitled to instead of guessing. I do not want to complicate this simple statement by going into minute details, as, for instance, acetonuria, different tolerance for different species of meal (wheat, corn, potato, and so on), but I owe the reader *a motive for the title of* this paper. Here it is.

I stated that cases were frequent in which different symptoms would point to the diagnosis of diabetes and yet the urine would not show any trace of sugar. These symptoms are the well-known premonitory signs of diabetes, affections of the skin, pruritus, fall of the hair, &c. In many cases of the kind I could find a hyperglycæmia and the symptoms would subside after an appropriate light antidiabetic treatment. The following cases are very interesting.

A. B., a Brazilian, consulted me on July 3rd, 1912, with acne *furunculosa of the face* and the diagnosis of "gouty disposition," on account of which he had been *advised not* to eat too much meat and nitrogenous food, but more green food, fruit, and carbohydrates. He had no sugar in the urine, yet his blood test showed 0·16 per cent. before breakfast—i.e., hyperglycæmia—which subsided readily on appropriate treatment, as also did the furunculosis. It is obvious that his previous diet had been just the reverse of *that which it ought to have been.*

A compatriot of A.B. called on July 18th of the same year. He was very obese, and although his urine was all right he was afraid of diabetes on account of similar cases in his family. Fortunately, his fears were not well-founded, his level being at 0·10 per cent., within normal limits.

A. B. had suffered for two years from sycosis and general furunculosis. There was no sugar in the urine, but 0·23 per cent. after 100 grammes of dextrose and *0·16* without taking anything in the morning.

---

[3] For special details see the publications given in preceding footnote.

[4] At Georg Thieme's, *Leipzig*, 1907.

[5] The above-mentioned or similar food tables will give the percentage of carbohydrates contained in different kinds of food; for example, boiled potatoes 21, mashed potatoes 5, cocoa 34·2, cauliflower (boiled) 3·5, asparagus 1·3, soups of cereals 7, nuts 13, almonds 7·3, oranges 5·3, apples 12, and so on.

Another very interesting case was that of a patient whose family medical attendant had found sugar in the urine, while another practitioner on the same day had found none. The latter was right, because after examination there were a great many reducing substances in the urine, but no sugar. Yet the blood test showed (July 15th, 1912) 0·30 per cent. before breakfast—i.e., hyperglycæmia.

Whether these and similar cases of hyperglycæmia will end in real diabetes time alone will show. At any rate, experience teaches that diabetes, of all affections, should be attended to as soon as possible, and the examination for blood sugar is the proper means for its early detection.

We began our researches in response to the demands made by our daily practice in the treatment of diabetics. But comparisons of our method with the old ones, working with great quantities of blood, show that it holds good also for the purpose of physiological and clinical study, so far as sugar is concerned.

Since Adler and I published our first article in November, 1912 (showing that with the aid of highly diluted solutions it was possible to get trustworthy and accurate sugar estimations from the analysis of a few drops of blood obtained by a simple needle-prick), as always happens, others have seized upon our idea, modifying one of the many old procedures, or even adapting new ones, to our method. But we claim that we were the first to lead the way. We cannot see that any of the methods since published are simpler, quicker, or more trustworthy than ours, and until we find a better one we shall stick to it.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF PNEUMONIA PRESENTING SOME UNUSUAL FEATURES.

By A. AINSLIE HUDSON, M.D. EDIN., F.R.C.S. EDIN.

THE following case may prove of some interest by reason of its infrequent features. Indeed, if physical signs mean anything, they meant in this case that the two forms of acute pneumonia were present at one and the same time in the same individual.

The patient, aged 62 years, came under my care with a history of a definite rigor and other symptoms suggestive of a chill. The physical signs were for the most part indefinite when I first saw the case, the first definite signs being those associated with a small patch of pleurisy at the left base. On the second day towards evening the temperature rose to 103·6° F., with pulse and respirations in close attendance, and there was some cyanosis. On the third morning the temperature had fallen to normal, likewise the pulse and respirations, and the cyanosis had for the most part disappeared, so that one was constrained to consider the case as a sharp attack of influenza or possibly only a simple chill with some respiratory symptoms. However, towards evening the temperature rose again to 100·5°, the sputum became rusty and very viscid, physical signs made their appearance in both lungs, and the patient's general condition became worse. On the fourth morning the temperature had again fallen to 99°, rising to 101° at night, the general condition remaining much the same in spite of the rapidly extending involvement of the lung tissue. On the fifth day the temperature was normal again, rising to 100·8° at night, the cyanosis increased, and there were periods of semi-delirium. On the sixth morning the pulse began to fail, coma set in, and the patient died suddenly at 8 o'clock, five and a half days from the onset of the disease.

The solidification of the left lung had begun on the third day, and by the fifth day the whole lung was more or less involved. While this process was going on in the left lung the right had begun to show isolated patches of catarrh, but by the end of the fifth day there was hardly a clear area to be found, although there was no consolidation to speak of. The pleurisy had only spread slightly and there was no effusion. Some emphysema was present towards the end. The tongue remained clean throughout. To summarise briefly, the pulse and temperature behaved more like in a case of out-and-out broncho-pneumonia, and one would have been inclined to consider the case as such had the catarrhal signs showed first, but they only appeared subsequently to the evidence of consolidation in the first lung, which eventually involved that organ from base to apex, whereas in the catarrhal lung there was no marked consolidation. The temperature on three mornings had been normal, and the pulse and respirations had greatly improved. The temperature never went above 101° except on the second evening when it rose to 103·6°, and there was no doubt about the consolidation of the left lung, which presented signs entirely absent in the other lung. The patient was put into a hospital and seen by three other practitioners who confirmed my opinion. The usual treatment was employed.

Llandrindod Wells.

A RECORD OF ANÆSTHETICS AND ITS STATISTICAL LESSON.

By D. J. MUNRO, M.B., B.S. LOND.,
ANÆSTHETIST TO THE LONDON THROAT HOSPITAL.

OUT of nearly 2000 administrations during the last two years notes were kept relating to complexion, speed of induction, and depth of anæsthesia in about 200 cases. This was done with no very definite object beyond a curiosity as to what results might emerge. Apparent variations in the tables (averaging an error of less than 3 per cent.) are due to differences in the anæsthetic agent given, the figures for nitrous oxide and ethyl chloride—though most used—being too small to be employed for statistics. Table I. suggests that fair subjects are somewhat more susceptible to the effects of anæsthetics than dark ones, not only with regard to the rapidity with which they can be put to sleep, but also in respect of the depth of anæsthesia resulting. Table II. sounds a warning against too rapid induction, since it indicates that rapid induction is much more likely to be followed by deep anæsthesia than slow induction; but this warning is qualified very considerably by Table III., which shows that almost all the cases of deep anæsthesia following rapid induction occurred when ether was

the principal anæsthetic given, while with chloroform or C.E. mixture as the principal anæsthetic it was nearly always easy to maintain a light degree of anæsthesia, whether induction had been speedy or slow, and it may be legitimately deduced from this table that for difficult nose and throat operations, where it is of the highest importance to preserve the coughing or swallowing reflex, chloroform is undoubtedly the anæsthetic of choice, while for operations on the trunk or limbs, when deeper anæsthesia is either advantageous or of no particular moment, ether is to be preferred, especially by those who give anæsthetics comparatively seldom.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

Exhibition of Cases.

A MEETING of this section was held on April 16th, Dr. J. J. PRINGLE, the President, being in the chair.

Dr. GEORGE PERNET showed a case of Double Primary Chancre of the Lips in a man. The patient was first seen on March 17th, suffering from a roseolar and papulo-squamous eruption on the body which had been preceded at an interval of five weeks by the sores on the lips. There were no lesions on the genitalia. Neosalvarsan (0·9 grm.) was injected intravenously on March 22nd, and this was followed by some diarrhœa, abdominal pain, and a toxic erythema on the hands and knees.—Sir MALCOLM MORRIS asked when the last Wassermann reaction had been tested.—The PRESIDENT inquired if there was a history of the patient having smoked another person's pipe, and if the toxic eruption was regarded as a "Herxheimer's reaction." In his experience multiple chancres of the lips were not very uncommon.—Dr. A. M. H. GRAY asked if the neosalvarsan was used in concentrated or in dilute solution, his experience being that the concentrated solution was not followed by severe reaction.—Dr. ARTHUR WHITFIELD regarded Herxheimer's reaction as a specific reaction of syphilitic tissue to salvarsan, but did not consider the case under discussion as an example of it.—Dr. F. PARKES WEBER asked if the fauces were involved in the erythema.—In reply to the PRESIDENT, Dr. H. MACCORMAC said he had not observed the Herxheimer reaction so frequently after neosalvarsan as after the old salvarsan, and Dr. GRAY said he had seen it more often after small than large doses.—Dr. PERNET said the Wassermann reaction had not been tested, the manner in which the disease was contracted had not been ascertained, and, as the patient was suffering from a syphilitic throat, it was impossible to say if the fauces were involved in the toxic erythema. He questioned the utility of retaining the term "Herxheimer's reaction" and doubted its specificity.

Dr. W. KNOWSLEY SIBLEY showed a woman, aged 35, suffering from Symmetrical Telangiectases of the Face, Mucous Membranes of the Mouth and Conjunctivæ, which had begun on the face six months previously. The patient had suffered from a similar attack six years ago and was then under the care of Dr. H. G. Adamson. Her sister was stated to have a similar condition affecting the abdomen.—Dr. ADAMSON said the patient had been shown by him six years ago, and the condition had not altered in any way.—The PRESIDENT interrogated the patient closely as to the disappearance of the lesions, and she was quite certain that this had occurred.—Sir MALCOLM MORRIS said he had seen spider nævi disappear spontaneously, and Dr. O. DUDLEY CORBETT had observed the same phenomenon after pregnancy.—Dr. PARKES WEBER said the spider nævi of very young children might disappear, and also those accompanying jaundice and liver disease in adults. Dr. Sibley's case came into the category of multiple telangiectases of the skin and mucous membranes with a tendency to bleeding which had been described by Sir William Osler and others. Referring to the presence of De Morgan's spots in the case, he agreed with the exhibitor that they were not specially associated with abdominal cancer.—Dr. MACCORMAC mentioned a case of Dr. Pasteur he had observed in which a large number of multiple telangiectases occurred in a patient suffering from gastric ulcer, and which had completely disappeared.—Dr. WHITFIELD discussed the varieties of nævi with reference to the case exhibited: a nævus in the continental sense of the word was a congenital anomaly of the skin, but so-called "spider nævi" often followed the bites of flies and mosquitoes and were minute traumatic aneurysms. The type associated with cancer were not true nævi. He regarded the case as a nævus.—Dr. GRAY remarked that stellate nævi were sometimes associated with cirrhosis of the liver, and inquired if Dr. Sibley had investigated the case from this point of view.—Dr. J. M. H. MACLEOD remembered a patient in whom typical telangiectatic lesions accompanied gastric ulcer; he looked upon the case under discussion as a congenital spider nævus.

Dr. SIBLEY also showed a woman, aged 27, who presented small Punctate Hæmorrhages of 13 weeks' duration, scattered over the chest, back, and shoulders, and hæmorrhages in the mouth. The patient also had multiple furunculosis and pyorrhœa alveolaris.

Dr. G. NORMAN MEACHEN brought forward a girl, aged 15, with persistent Erythema of the Legs of 2½ years' duration accompanied by severe pain, which was increased by the dependent position and was unrelieved by salicylates. There was also passive congestion of the hands. Her heart sounds were normal.—Dr. PARKES WEBER thought the erythema was of the type seen in Bazin's disease.—Dr. ADAMSON said the erythema of that condition was of the "livedo" type, but the present case was diffuse.—Dr. WHITFIELD did not consider the cyanosis of Bazin's disease was a sufficiently important factor upon which to found a diagnosis in the absence of nodose lesions.—The PRESIDENT asked if there was any tuberculous taint in the patient or in her family; his general appreciation of the case agreed with Dr. Whitfield's. He remembered two similar cases which had recovered after puberty.

SECTION OF OTOLOGY.

Exhibition of Specimens and Cases.

A MEETING of this section was held on April 17th, Mr. RICHARD LAKE, the President, being in the chair.

Mr. G. H. L. WHALE exhibited the specimen of a Temporo-sphenoidal Abscess from a fatal case in a girl, aged 8 years, who had had otorrhœa for three weeks, and was taken to hospital on the second day after the onset of drowsiness. In the left meatus were fœtid pus and a polypus. Mastoid signs were absent, but there were marked ptosis and slight dimness of the edge of the optic disc. On the opposite side there were paresis of the orbicularis oris and marked dimming of the edge of the optic disc. These signs on the right side soon disappeared. The temperature and knee-jerks were normal, and there was no head retraction. The labyrinthine caloric responses were normal but sluggish. The cerebro-spinal fluid was neutral and non-reducing. At the radical mastoid operation a little pus was found in the antrum, but no fistulæ. On incision of the dura there was immediate pulsation and the formation of a hernia. The temporo-sphenoidal lobe was explored in all directions, but no pus was found. On the fourteenth day the temperature commenced to rise, and on the seventeenth had reached 104° F., but with no symptom except projectile vomiting. The cerebro-spinal fluid was under pressure, and there was a considerable increase of lymphocytes, and some polymorphonuclears were found.

Vomiting now ceased, but the temperature became subnormal and drowsiness increased. A second operation was performed on the twenty-fourth day, when about 2 dr. of offensive pus was evacuated from the temporo-sphenoidal lobe. A diphtheroid organism was recovered in pure culture. The drowsiness passed into coma and death occurred on the twenty-eighth day, after half an ounce of pus had been evacuated. At the necropsy the lateral sinus was found to be natural, but a large gangrenous abscess occupied the whole length of the under surface of the temporo-sphenoidal lobe—3½ inches.

Dr. DAN MCKENZIE showed a woman, aged 41, *illustrating* the Association of Nerve Deafness and Anæmia. A complicating feature was practically universal pyorrhœa alveolaris. He deferred judgment as to a causal connexion until he had observed whether the two conditions improved *pari passu*.

Mr. E. D. D. DAVIS exhibited an interesting case of Tuberculosis of the Mastoid in a male child aged 11 months. The patient was taken to hospital with an abscess of the superficial parotid glands, enlarged posterior auricular and upper deep cervical glands on the left side, left otorrhœa, and left facial paralysis. The parotid abscess was opened and curetted, and the enlarged cervical glands removed. Four months later a radical mastoid operation was performed, and more caseating cervical glands were removed. As the mastoid was still suppurating 12 months later the region was opened up, and the large sequestrum exhibited was removed from behind the lateral sinus. The disease was now arrested.—Dr. W. JOBSON HORNE contended that so-called primary tuberculosis of the ear was essentially a bone tuberculosis, starting in the mastoid process itself, not in the ear proper. In this remark he did not include cases of secondary invasion. In similar cases he had noticed a tendency to overlook the ear disease owing to the enlargement of the glands, so that the mastoid had been dealt with only subsequently. If the glands were left for a time it might be unnecessary to deal with them. The absence of pain was also apt to lead one away from the real source of the trouble.—Dr. J. DUNDAS GRANT pointed out that the course of events referred to by Dr. Horne applied specially to young children, in whom there was often the separation of a comparatively large sequestrum. This should be the objective of the surgeon rather than the performance of a radical mastoid operation in these young subjects.—Dr. W. A. MILLIGAN suggested inquiry into the source of the milk supplied to the child. He agreed with Dr. Grant that a set operation in children with this condition was not often called for. He differed from Dr. Horne as to primary tuberculosis of the ear being essentially a bone disease; he (the speaker), from the cases he had followed up, believed that the disease first attacked the mucous membrane, but bone involvement soon followed. He agreed that in operating it was advisable to leave the glands for a time, because he believed them to constitute a first line of defence. If it was clear that the basis of the inflammation was tubercle, the glands could be removed later.—Mr. WHALE described a case in which leaving the enlarged glands to be dealt with later proved to be wrong, for the result of doing the bone operation first was that the glands broke down before the operation wound healed, and the patient had a very bad neck.

Dr. G. F. STEBBING and Mr. G. J. JENKINS showed a postmortem specimen of Malignant Disease of the Ear which had become very extensive, involving the lower part of the mastoid, and extending downwards to the level of the thyroid cartilage, backwards to the posterior border of the sternomastoid muscle, and forwards to the angle of the jaw. A soft, readily bleeding polypus was showing at the orifice of the right external auditory meatus. The growth involved the middle fossa of the skull.

Mr. JENKINS exhibited, and demonstrated by means of the epidiascope, some beautiful serial microscopical sections of the left temporal bone of a female aged 59. There were ankylosis of stapes and other changes in the region of the foramen ovale—otosclerosis. He also showed microscopical sections of mastoid, labyrinth, and middle-ear tract of temporal bone of a young adult male, who was very ill with phthisis, and was also suffering from deafness, otorrhœa, and facial paralysis. The preparations showed the presence of pus in the middle-ear tract, with mastoiditis and labyrinthitis.

MEDICAL SOCIETY OF LONDON.

Cerebro-spinal Syphilis.

A MEETING of this society was held on April 27th, Sir DAVID FERRIER, the President, being in the chair.

Dr. PURVES STEWART read a paper on the Diagnosis and Treatment of Cerebro-spinal Syphilis, including Tabes and General Paralysis. He spoke of the importance of the early diagnosis of the condition, emphasising the fact that a pre-clinical stage occurred. Organic changes preceded the earliest clinical symptom. The clinical stage was relatively late. It was during the pre-clinical stage that treatment was most likely to be effective. Fortunately, however, the disease might be recognised in this stage by examination of the cerebro-spinal fluid and of the blood. He then referred to the methods of examination of these fluids. The modern neurologist was no longer satisfied with the absence of clinical signs and symptoms indicating gross focal disease in the nervous system, even when the Wassermann reaction in the blood was negative. To assure himself that the central nervous system has escaped he examined the cerebro-spinal fluid. There were three distinct kinds of lesions: (1) gummata, rising in non-nervous tissues, and compressing or invading the brain or spinal cord, or diffuse gummatous infiltrations; (2) syphilitic endarteritis, frequently culminating in thrombosis; and (3) parenchymatous nervous diseases, characterised by a primary decay and degeneration of various nerve tracts and nerve cells, produced by the direct action of the syphilitic toxin. Examples of the last group were certain primary forms of optic atrophy, a considerable part of the lesions of tabes and general paralysis, Erb's syphilitic paraplegia and certain forms of organic nervous disease occurring in the children of syphilitic parents. Gummata might often be removed by medicinal means, and if the nerve structures had not undergone destruction recovery might be complete. In syphilitic vascular diseases the lesions in the arterial wall might yield to treatment, but if thrombosis had occurred and an area of softening resulted the damage must necessarily remain. Lastly, with regard to the primarily degenerative diseases, such as tabes and general paralysis, these had generally been uninfluenced or only slightly alleviated by antisyphilitic treatment. The present day treatment by a combination of mercury with salvarsan or neosalvarsan was applicable to cerebro-spinal syphilis if certain precautions were borne in mind. It was safer to give repeated doses of not more than 0·03 grm. salvarsan, for it was less likely to be followed by nerve relapses. Patients with renal disease or marked cardio-vascular disease were unsuited for this treatment. Dr. Stewart then gave examples of cases in which cerebro-spinal syphilis of the gummatous and vascular forms had been treated by the new methods. He then dealt with the treatment of parenchymatous nervous syphilis, pointing out the several reasons which rendered it singularly resistant to treatment. In order to reach and destroy the organisms to which it was due remedies must enter the cerebro-spinal fluid. This might be effected by administering salvarsanised blood serum intrathecally or by the direct injection of neosalvarsan into the cerebro-spinal fluid. Within the last six months he had treated 25 cases of parenchymatous nervous syphilis, including 13 of tabes and 9 of general paralysis, by one of these methods. Composite tables of (1) 11 cases of tabes and (2) 7 cases of general paralysis were exhibited and other *detailed tables* of individual cases. The composite tables showed generally a great decrease in the lymphocytosis of the cerebro-spinal fluid, whilst the Wassermann reaction of the blood and cerebro-spinal fluid tended to diminish or disappear. Enesol had proved useful in the treatment of the lightning pains of tabes, and had the advantage of being suitable for simple hypodermic injection. Acting on the known beneficial influence of pyrexia on general paralysis, he had treated this disease by inducing artificial pyrexia by means of large intramuscular injections of sodium nucleinate. Of 15 general paralytics thus treated by Donath, three were able to resume their ordinary work, six were improved, five were unchanged, and one died of apoplexy during the treatment. His own cases had provided a moderate amount of encouragement, for as far as he had been able to judge a more or less prolonged remission occurred in the clinical symptoms accompanied by a diminution in the intensity of the lymphocytosis of the cerebro-spinal fluid in a considerable proportion of cases. He knew of no case, however, in which a cure had resulted. Urotropin was amongst the drugs which had proved useful as accessories in the treatment of general paralysis. He then related some of the results obtained in general paralysis by combined intravenous and intrathecal treatment, either with salvarsanised serum or with neosalvarsan. Other methods besides that of lumbar puncture might be employed to introduce remedies into the cerebro-spinal fluid. Thus this might be done by cranial puncture or through the orbit by penetrating the sphenoidal fissure with a hollow needle, or remedies might be injected directly into the ventricles of the brain by the callosal puncture of Anton and Bramann. When comparing intraspinal with intracranial administration it must be borne in mind that a long series of treatments was necessary, and it must be considered whether it was justifiable to submit a patient to the risks of repeated cranial operations unless these could be shown to yield results materially better than those obtained by intraspinal injections. In every one of the cases of general paralysis he had treated by the latter method the lymphocytosis of the cerebro-spinal fluid had diminished. In three of them the Wassermann reaction disappeared from the blood. In the cerebro-spinal fluid the Wassermann reaction usually became less marked, but in only one did it disappear. Before coming to definite conclusions numerous and prolonged observations over a large series of cases were necessary. Improvement in the condition of the cerebro-spinal fluid was a useful index, but we must remember that in general paralysis, at least, the cell count in the fluid might go down without any improvement in the mental symptoms. It was therefore important to select only those cases of general paralysis which were in the early or toxic stage of the disease, before the cortex had become profoundly degenerated. The earlier the disease was recognised the better were the prospects of improvement. Advanced cases were unsuitable. The most thorough method of attacking general paralysis would be to administer remedies concurrently by all three routes—intravenously, intraspinally, and intracranially, and it might be that in the future this combination would be adopted. It was too early to claim that we possessed a cure for tabes or general paralysis, but we could do a good deal towards arresting both diseases. Whether such arrest was permanent or not, time alone would show.

Mr. C. A. BALLANCE said he thought that in ordinary cases of syphilis the combined method of intramuscular injections of mercury and intravenous injections of salvarsan was the best form of treatment. In 83 so treated of which he had knowledge 80 developed no secondary symptoms. If this procedure were adopted one would not see cerebro-spinal syphilis so often. A simple method of obtaining a rise of temperature was by the injection of Coley's fluid, and possibly this might be of use in cerebro-spinal syphilis if a rise of temperature was desirable. The arachnoid membrane very definitely separated the subdural space from the subarachnoid, as was shown by clinical instances as well as by the work of Key and Retzius. It, therefore, seemed proper to inject salvarsanised serum or salvarsan into the subarachnoid space and not into the subdural. He did not consider it more dangerous to inject them into the intracranial subarachnoid space than into the spinal. The method he had adopted was to make an opening into the skull immediately in front of the bregma, and pass down a fine cannula 3 inches long through the anterior part of the corpus callosum into the anterior cornu of the lateral ventricle. The guide was the falx. The diameter of the cannula was 1 mm. A stilette ran through the cannula and, projecting slightly beyond it, protected the nervous tissue from serious damage. He had used from 30 to 60 c.c. of salvarsan solution, preceded and followed by a little normal saline. He could not speak of the beneficial effects of the method, but no complications had occurred in the 5 cases so treated, and it seemed a satisfactory way of introducing salvarsan and salvarsanised serum.

Dr. F. E. BATTEN did not think that parenchymatous syphilis was generally uninfluenced by treatment in early cases; and in recent years he had thought antisyphilitic treatment useful in early tabes and general paralysis. He had treated two cases of general paralysis which had resisted ordinary remedies by sodium nucleinate without improvement. The Wassermann reaction and cell content of the cerebro-spinal fluid had remained unaltered. He had used undiluted salvarsanised serum in one other which had not been benefited by mercury, but also without good effect. He spoke of the danger of injecting either salvarsan or neosalvarsan intrathecally.

Dr. ROBERT ARMSTRONG-JONES said he had given up mercury in the late stages of general paralysis. Pneumonia frequently occurred in general paralytics, but they were very rarely indeed improved by the resulting rise of temperature, in this way contrasting with the subjects of certain other forms of lunacy. Almost complete recovery might be seen in patients who appeared to have definite parenchymatous degeneration without treatment. The use of a thorium hydroxide cap had been followed by marked improvement, and in two cases by apparent recovery. He had experienced little benefit by the use of neosalvarsan, and regarded lumbar puncture as a dangerous procedure. There were 60 cases on record in which the operation of piercing the frontal bone had been performed, but it seemed to him a most difficult operation. In 330 cases of general paralysis he had found that the average duration from admission until death was one year and four months.

Dr. GORDON J. LANE, speaking of the treatment by nucleinate of soda, said that it led to a decided improvement and an increase in the red blood corpuscles and a leucocytosis chiefly of the large lymphocytes.

The PRESIDENT complimented Dr. Stewart on his paper, and especially on the critical manner in which he had stated his conclusions. He was a little disappointed in the results of the intrathecal method of treatment. It could not yet be said that any case was on record in which parenchymatous syphilis was cured by it. The only hope lay in the treatment of very early cases. In the one case in which he had seen neosalvarsan tried the result was disastrous, all the symptoms being intensified.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on April 3rd, Dr. T. WARDROP GRIFFITH, the *President*, being in the chair.

Dr. O. W. VINING showed: 1. A case of Left-sided Hemianopia (partial) in a man with a history of convulsive attacks, preceded by auræ of flashing lights. A provisional diagnosis had been made of a tumour involving the right occipital cortex. 2. A case of Paralysis Agitans in a woman aged 56. The patient began to lose the use of the right arm eight months ago; the tremor was noticed in November, 1913, and since then the condition had rapidly developed.

The PRESIDENT showed: 1. A case of probable Intracranial Tumour in a boy aged 5. The sixth cranial nerve of the left side was involved and there was right hemiplegia. Optic neuritis was marked in the left eye, and commencing in the right. 2. A case of Progressive Muscular Atrophy in a man aged 46. The disease began eight months ago with weakness of the right hand. Ulnar deviation was well marked and bulbar signs were present. The reflexes were increased, proving involvement of the upper motor neurons. Treatment by strychnine injections was being carried out.

Dr. G. W. WATSON and Mr. ALEXANDER D. SHARP showed a woman with Mitral Stenosis and Paralysis of the Left Vocal Cord. The patient came under observation with hæmoptysis, as a case of suspected phthisis. There was no clinical evidence of phthisis, but undoubted signs of mitral stenosis. There had been complaint of huskiness for some time, and laryngeal examination showed a complete paralysis of the left vocal cord. In addition there was impaired sensation on the left side of the tongue and on the left anterior faucial pillar. The patient had to be careful in the act of swallowing as she was apt to "choke."

Mr. R. LAWFORD KNAGGS showed: 1. A man with an Œsophageal Fistula traversing the right pleura. The case had been exhibited at the last clinical meeting and the passage of swallowed milk through the fistula demonstrated. There was a three years' history of intermitting pleural suppuration. Gastrostomy was performed and the patient was fed by the stomach till recently. He was now taking solid food, and apparently nothing came through the fistula. 2. A case of Excision of Tuberculous Wrist in a man. When treatment by trypsin injections was commenced some six months ago the arm looked hopeless, and the treatment was given a chance before amputation was definitely decided on. Improvement speedily set in and had progressed steadily.

Mr. J. F. Dobson showed a case of Diffuse Papillomata of the Bladder treated by suprapubic cystotomy, and subsequently by implantation of both ureters into the colon. The patient was perfectly comfortable and able to retain urine for five hours. The suprapubic wound was healed and nothing escaped from the bladder.

Cases were also exhibited by Mr. W. Thompson, Mr. J. A. Coupland, Mr. H. Secker Walker, and Dr. A. L. Whitehead.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Congenital Icterus.—The Relation between the Mechanism and Management of the Third Stage of Labour.—Exhibition of Specimens.

A meeting of this section was held on April 3rd, Dr. M. J. Gibson, the President, being in the chair.

Mr. Spencer Sheill read a paper on Congenital Icterus. —Dr. E. Hastings Tweedy said that he had seen a great many cases of jaundice in infants, some of which had terminated fatally, and he had seen a good many post-mortem examinations on these cases, and was surprised at the number of defective ducts found. He was particularly interested in the suggestion that these cases should be subjected to surgical interference. He had not heard it suggested before. Infants bore abdominal section badly, and this was more particularly true of jaundiced infants. He inquired if there were any statistics of successful operations in these infantile illnesses. He mentioned that infants were frequently starved for want of water, and suggested that they did not get enough fluid in the early days after birth. He thought that jaundice arose from want of sufficient fluid, and that this was particularly the case in premature children. He pointed out that children were kept in a hot atmosphere and required a good deal of water. He wondered if the insufficiency of water would account for the viscosity of the bile. —Dr. Gibbon FitzGibbon asked whether at the operation on the gall-bladder it was possible to make out if it was an obstructive jaundice; also what was the condition of the liver? Was there any enlargement or anything which would suggest a syphilitic condition?—Dr. Spencer Sheill, replying to the remarks, said on examination the liver appeared in every way normal. There was no discolouration or enlargement, and it was not unduly hard or soft. He recognised that everybody was against laparotomy in infants, as they were in nearly 90 per cent. fatal. The literature on the subject was very scanty, but a few men who had operated said that operation gives bad results unless distinct obstruction was found in the duct. In his case he did not think the gall-bladder was so distended as to indicate obstruction, and the surgeon reported that the ducts were patent. He considered septic cord cases quite distinct. He was very particular about the prevention of over-clothing of infants, thereby sweating them, and not making up for it by water taken. In replying to a question from Dr. Bethel Solomons, he said that the parents refused any interference in the way of a Wassermann test, and from the history no information of any value could be elicited.

In the absence of Dr. J. R. Freeland, Dr. Tweedy read his paper, entitled the Relation Existing between the Mechanism and the Management of the Third Stage of Labour: a report of 2000 cases from the Rotunda Hospital. —The paper was not discussed.

Dr. Bethel Solomons exhibited a Uterus with Cervical Myomata removed from a patient 37 years old, who had been married 11 years. In her first three years of married life she had two healthy babies who are still alive. Two years later she had an eight months' stillborn child; two and a half years later a nearly full-term stillborn child. In January, 1911, examination under an anæsthetic revealed an enlarged uterus with lacerated cervix and rectocele. Dr. Solomons performed curettage, trachelorrhaphy, and colpoperineorrhaphy. The curettings were found to be glandular endometritis. The patient enjoyed good health for about six months, when she became pregnant again, and was treated with potassium iodide and mercury during the pregnancy. At six months she was delivered of a macerated fœtus. This was examined by Professor P. T. O'Sullivan, who reported that there was no trace of the spirochæta pallida. A year ago menorrhagia and metrorrhagia started. These symptoms became aggravated in the last six months, and severe backache troubled her during the last two months. Dr. Solomons found a uterus in normal position with two large myomata, one growing from the back and the other from the side of the cervix. It might be asked why he did not perform myomectomy, which appeared from the specimen might have proved easier. He performed hysterectomy for the following reasons: (1) The age of the patient; (2) her fear of having more macerated babies; and (3) the fear of malignant degeneration having commenced. Dr. A. Stokes, who examined the specimen, reported as follows: "Endometrium, glandular endometritis. Myoma, simple, with early mucoid degeneration. Cervix normal." It was difficult to account for the frequent stillborn babies. Syphilis, endometritis, and tumours are generally regarded as the most common predisposing factors. There was evidently no syphilis. The endometritis might have accounted for the first two, but this was cured and could not have accounted for the last. The tumours were not present until two years after the birth of the first two, and until one year after the birth of the last stillborn child.

Dr. Tweedy showed a specimen of Myoma, recently removed, which had undergone mucoid degeneration.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on April 17th, Dr. A. K. Chalmers, the President, being in the chair.—A paper was read by Dr. B. A. Peters, lecturer on infectious diseases, Bristol University, on the Elimination of Cross Infection in Fever Hospitals, in which he pointed out that, although surgery had long since abandoned the idea of the air being an appreciable factor in the conveyance of infection to a wound, medicine still regarded it as being the principal medium in the carriage of the common infectious diseases of children. At the Bristol fever hospital all patients were kept in bed for a fortnight after admission. During that time any secondary infection which might be incubating would have developed, and if the case were a doubtful one a definite diagnosis could be made. Each patient was provided with a separate towel, face-flannel, piece of soap, comb, and throat-brush, which were kept in a locker beside the bed. All eating utensils were boiled after each meal, and other utensils were cleansed and disinfected after use. The nurses wore rubber gloves lined with canvas when closely handling a patient, which were immersed in perchloride of mercury solution before going on to the next patient. These methods had been quite successful in preventing the spread of scarlet fever, diphtheria, whooping-cough, rubella, or mumps when accidentally introduced into a ward not intended for their reception. Previous to the introduction of this system in 1911 about 2·5 per cent. of the patients contracted a second disease while in hospital, the only available means for limiting the number of secondary cases after the removal of the infecting patient being to cease admissions to the infected ward until the secondary infection became extinct for want of further susceptible patients. In the first year after the introduction of the new system only two patients contracted measles and one chicken-pox. The next step was to keep the windows of the acute wards open all the year round, which procedure was completely successful in preventing the spread of secondary infection in those wards in spite of 13 invasions of chicken-pox. One important result of aseptic nursing was a marked diminution of late septic complications, including especially rhinitis. During the past two years the minimum detention period in the Bristol fever hospital had been reduced to one calendar month in the case of scarlet fever, desquamation being ignored.—Dr. Robert Milne maintained that by swabbing the tonsils and pharynx with 10 per cent. carbolic acid every two hours for 24 hours, and rubbing eucalyptus oil over the patient until the tenth day of the disease, cross infection was completely prevented.—Dr. G. S. Buchanan pointed out the importance of taking into consideration the limitations of all experiments in the infectivity of disease, for each infectious disease must have its own natural history, and infectivity was greater at one time than it was at another. He considered it highly probable that a reduction in the number of septic cases would result from the extreme care taken in regard to secondary infection.—Mr. E. H. T. Nash, referring to the success attending Dr. Milne's own cases, pointed out that it was possible for him to begin to treat the cases occurring in the Barnardo Homes much earlier than a medical officer of health could begin treatment in an isolation hospital.—Dr. Meredith Young insisted upon the importance of getting cases into hospital early and of avoiding overcrowding. It was important also to recognise that otorrhœa and rhinitis were definitely communicable. He did not believe that infection was in the skin. Children were sent out of the Stockport hospital when peeling, but secondary infection rarely resulted.—Dr. G. F. Buchan maintained that Dr. Milne's treatment was no treatment at all, yet his results appeared to be the same as those of Dr. Peters, who practised strict asepsis with abundant fresh air.—Mr. T. W. N. Barlow said that he had tried Dr. Milne's treatment thoroughly for four years, but he got return cases and cross infections as frequently as ever.—The President referred to the enormous demand which aseptic treatment made on the nursing staff, and spoke of the great value of the use of gloves. He pointed to the possibility of there being some change in the organism of scarlet fever which was producing lessening virulence of infection.

GUY'S HOSPITAL: LECTURES ON INDUSTRIAL DISEASES.—The following is the syllabus of the six lectures on Industrial Medicine to be delivered at the Medical School of Guy's Hospital by Dr. Frank Shufflebotham during May and June:—Lecture I., May 8th: The Symptoms and Diagnosis of Lead Poisoning. Lecture II., May 15th: The Post-mortem Appearances associated with Lead Poisoning. Lecture III., May 22nd: Miners' Nystagmus, with a demonstration on living cases. Lecture IV., May 29th: Industrial Fibroid Lung. Lecture V., June 5th: Anthrax. Lecture VI., June 12th: The Medical Aspect of the Workmen's Compensation Act. The lectures will be given on Friday afternoons at 4 P.M. in the pathological theatre.

VICTORIA HOSPITAL, BURNLEY.—A proposal to increase the number of beds in the Victoria Hospital, Burnley, has prompted Dr. John Brown, now of South Africa, to write an interesting letter which appeared in the *Burnley Express* on April 25th. Dr. Brown, who at one time resided in Burnley, identified himself with many movements in that town which had for their object the betterment of the poor, and among these movements was the building of the Victoria Hospital, which for the past 28 years has ministered to the medical needs of the town and district. The Victoria Hospital adopted the circular ward system, and so successful has this system proved, that the "Victoria Hospital wards," writes Dr. Brown, "are an example to the whole world as to the best manner of heating and ventilating, and in providing the largest possible floor space in the least expensive manner"; and he suggests an additional storey to the present building as the best means of providing space for new beds. That the board of management have a difficult financial problem to consider is also recognised by Dr. Brown, when he says: "In the present unprecedented deplorable state of the cotton trade in Lancashire, with its very gloomy outlook for the future, your hospital extension must be conducted in the cheapest possible manner." Dr. Brown discusses the financial aspect of the question, and argues that an additional storey, for which the building is structurally suitable, would be better in every respect than the erection of new detached buildings. The letter, which is virtually a plea for, and an appreciation of, the circular system of hospital wards, will be read with interest by everyone concerned with the building of hospitals, and should receive the careful attention of the board of management of the Victoria Hospital, considering the personality of its writer.

Reviews and Notices of Books.

Theorie und Praxis der Inneren Medizin.

Von Dr. E. KINDBORG. Band III. With 71 illustrations. Berlin: S. Karger. 1914. Pp. xiv. + 752. Price 13 marks.

WE welcome the appearance of the third and last volume of Dr. Kindborg's text-book of internal medicine, which is designed for the use of practitioners and students of medicine. The diseases of the kidneys, blood, and nervous system are considered at full length in the greater part of the volume; the last 100 pages are devoted to the general infections and the chief acute and chronic poisonings, both receiving rather short shrift, as though for lack of space. The author's style is good, and his writing makes easy reading. The text is not overburdened with facts and figures, percentages and proportions, correlations between physical signs and post-mortem observations, and it does not contain a vast amount of detail in the sections devoted to treatment. The book is clearly not meant for the student who has examinations to pass, nor is it a bedside manual, if such an expression may be allowed, nor the sort of book to refer to when an obscure case has to be diagnosed. Dr. Kindborg writes spaciously, viewing the disorders he describes from a philosophical and physiological standpoint, dealing in general considerations rather than in the particulars of disease; he is at pains to show how physiological conditions may pass on into pathological, and gives impressionist pictures rather than detailed presentments throughout. Matters are brought rather more to a focus in the tables scattered throughout the text, but these, too, are lacking in the definiteness and dogma that one is accustomed to find in medical text-books.

Without doubt there are many medical men who will read Dr. Kindborg's volumes with pleasure and profit, particularly physicians of a contemplative rather than an active or operative cast of mind. To the pure practising physician it will not appeal to warmly, in spite of its many excellencies.

Practical Sanitation.

A Handbook for Health Officers. By FLETCHER GARDNER, M.D., Captain, Medical Corps, Indiana National Guard, and J. P. SIMONDS, B.A., M.D., Professor of Preventive Medicine, University of Texas. London: Henry Kimpton. 1914. Pp. 403. Price 18*s.* net.

THE authors state that their object has been to provide within the covers of a single moderately priced volume a plain, non-technical exposition of the duties of the health officer, and to provide him with a safe way of meeting any emergency which may arise. The work deals first with individual diseases and groups of diseases under the heading of "Epidemiology," next with various questions of general sanitation and sanitary organisation, and concludes with a brief summary of some principal laboratory methods. The volume is well illustrated and clearly printed, though curiously heavy for its size.

On the whole the authors have succeeded creditably in the task which they imposed upon themselves. The successive chapters are full of well-ordered information authoritatively or even didactically stated, and the information given is generally of the kind most needed for rapid reference by those who wish to know the outstanding facts of different epidemiological and public health matters. For sanitary work in this country the ground is already largely covered by more than one well-known English text-book, which have the advantage of dealing with English administrative conditions; but there are various matters, such as the chapters on rat destruction and the schedule for sanitary surveys of cities, on which this book will be found a useful addition to English libraries of public health, while it should be particularly serviceable to medical men practising in the colonies or abroad and away from general and special text-books of public health.

A few criticisms may be called for. The need for "a sanitary survey of the source" of a water-supply is mentioned, but by no means sufficiently insisted upon; a health officer often needs no support whatever from the laboratory work, on which much stress is here laid, to condemn a water to which polluting matters obviously can gain access. The absence of any sufficient account of the common forms of food poisoning seems a serious omission. The statements made on the matter of incubation periods might have been more explicit: thus the incubation of enteric fever is given vaguely as "one to two or more weeks"; and that from measles as "from 7 to 18 days, oftenest 14," without specifying whether the 14 refers to the initial symptoms or to the occurrence of the rash. The maximum incubation period of whooping-cough is generally held to be longer than ten days, and an obvious error has crept into the table on p. 81 which makes the incubation of scarlet fever "usually 14 days." The statement that the rash of small-pox usually makes its appearance on the fourth day of illness is contrary to general experience; exceptionally the rash may be delayed as long as this, but the rule is certainly the second or at most the third day.

A Treatise on the Diseases of Women, for Students and Practitioners

By PALMER FINDLEY, B.S., M.D., Professor of Gynæcology, College of Medicine, State University of Nebraska. London: Baillière, Tindall, and Cox. 1914. Pp. 954. Price 30*s.* net.

THIS book has grown out of the author's "Diagnosis of Diseases of Women." Much that was contained in the former work has been revised, the subjects have been rearranged, and more than an equal amount of text and illustrations has been added for the purpose of making a complete text-book on the subject of the diseases of women. The result is a bulky volume of some 950 pages and 632 engravings, with 38 plates in colours and monochrome.

A feature of the work is the large amount of space devoted to non-operative methods of treatment, such as douches, baths, exercise, massage, diet, dress, and tampons. Dr. Findley thinks that the non-operative methods of treatment of diseases of women have not received their due share of consideration in text-books and in practice. A great deal of this information is extremely useful; it is, however, a pity that the author should have included an account of pelvic massage, more particularly as this therapeutic measure finds little favour in America, while the mode of treatment, we imagined, had to a large extent been given up, even abroad, where at one time, as the author says, it was much practised. The date upon the title-page of this work is 1914, and it is therefore disappointing to find so little said as to the treatment of cases of fibromyomata by X rays.

Dr. Findley is not very enthusiastic on the merits of the extended abdominal operation for cancer of the cervix. At the same time, no doubt unwittingly, he misrepresents the present views of Wertheim. This operator does not attempt to remove the glands unless they are enlarged, and so far from the statement being true that in every case in which the removed glands were found the seat of metastasis there was recurrence, Wertheim has published no less than 14 cases in which the glands were involved at the time of operation and in which the patients were alive and well at the end of five years; and so long ago as 1911, in the record of his first 500 cases, he pointed out that the removal of all the glands is generally not possible and usually not necessary, for even at that date he had five patients, in whom the glands were involved, alive and free from recurrence five years after the operation. It is a pity that the operation of vaginal hysterectomy combined with bisection of the uterus should be illustrated in the section on carcinoma of the uterus, precisely the condition in which this method is unjustifiable.

We must not be thought from these criticisms to be of the opinion that this book is not a useful one. It contains a great deal of information, but there is a want of arrangement and an amount of repetition which detract from its usefulness, and which it would be easy to correct in any future edition. Personally, we are of opinion that a very complete account of the diseases peculiar to women could be given in a book of much less than nearly 1000 pages without anything of importance being omitted, and it is disappointing to find so much that is of value hidden among a large amount of information often of little moment. Dr. Findley's book on the "Diagnosis of Diseases of Women" was of such merit that we are disappointed to find this much more important work of less than equal worth. There are a very large number of mistakes in the spelling of proper names, such as Priestly, Schaffer, Fraub, Prochowick, Granger and Stewart, for Grainger Stewart, Leipmann, and many others. Many of the illustrations are good, and the index is a full one.

Practical Pathology, including Morbid Anatomy and Post-mortem Technique.

By JAMES MILLER, M.D. Edin., F.R.C.P. Edin., Lecturer on Pathology and Bacteriology, School of Medicine of the Royal Colleges, Edinburgh; Pathologist, Royal Victoria Hospital, Edinburgh. With 112 illustrations. London: A. and C. Black. 1914. Pp. 444. Price 7*s.* 6*d.*

THIS is essentially a student's book, and one that we can cordially recommend.

The early chapters are concerned with the equipment of the pathologist and the method of removing the various organs, &c., for systematic examination; these, together with the last chapter on necropsies conducted from the medico-legal point of view (of somewhat limited scope, since the procedure adopted in Scotland is alone dealt with adequately), and an appendix on microscopical and bacteriological methods, comprise the strictly practical portions of the volume. Ten other chapters are devoted to diseases of the various organs and structures, and one to a consideration of tumours in general. In this section of the work all the common pathological conditions are included. Each organ is taken in turn; the diseases likely to affect it are indicated, often in tabular form, the lesions are clearly described as to their naked-eye appearances, and, finally, a synopsis of the associated microscopical changes is given. All the descriptions are arranged in an orderly manner, and although brief are sufficiently comprehensive, and there is a refreshing absence of those minute details which render many of the manuals of similar scope so perplexing and so unsuited to all but the expert pathologist.

Following the illustration of the value of bacteriological investigations quoted on the second page of the book in connexion with the case of woolsorter's disease, we hoped to find this important matter insisted upon at every stage of the post-mortem examination, and the possible but often unsuspected infections noted in connexion with each organ, and we were correspondingly disappointed to find these matters relegated to an appendix in which they lose much of their effectiveness.

Some tables of weights and sizes of normal organs and structures might well have been included, as also some details of the methods and possibilities of extended inquiry when only restricted post-mortem examinations can be obtained. These shortcomings, however, are not sufficient to detract from the merits of the work.

Grundzüge für die Ernährung von Zuckerkranken nebst praktischen Anweisungen für die Diabetes Küche (nach weiland Dr. Gilbert's Diabetes Küche).

Von Professor Dr. ALBERT ALBU. Halle a.S.: Carl Marhold. Pp. 163. Price 4 marks.

ALTHOUGH based upon a book by Dr. Gilbert, giving directions for preparing and cooking food for diabetics, this book has a larger scope, and treats of the diet in this disease, both from the scientific and practical points of view.

It consists of five parts, the first of which is devoted to the principles concerned in the ordering of diets for diabetic patients. Diets are given in detail for the working out of the tolerance of the patient for carbohydrate and for the increase of his power in this respect, illustrative cases being quoted. Then special diets, such as the oatmeal, rice, potato, and vegetarian diets, are described and discussed.

The second part consists of tables of food materials, including those strictly forbidden, those allowed in definite quantities, and those permitted without stint. In the third part a careful description is given of special foods for diabetics. The difficulty of preparing a bread substitute at once palatable and of a character to satisfy the craving of the patients for bread is specially emphasised. The various meals, flours, cakes, and other preparations designed for the special use of diabetics are referred to, and the names and addresses of the makers are usually given. The fourth part contains some general observations upon prophylaxis and prognosis in diabetes.

The fifth part comprises nearly two-thirds of the book, and consists of directions for the preparation and cooking of dishes for *diabetic patients.* Instructions are given in detail for the making of hors d'œuvres, soups, and entrées, for the choice and cooking of fish and meat dishes, for the preparation of sauces, vegetables, edible fungi, jellies, salads, sweets, ices, and drinks. In every instance the directions given are explicit and sufficient.

The book is small and inexpensive, and it is systematic and easy of reference. It supplies a distinct want, and we can cordially commend it to our readers as both interesting and useful.

Kurzer Leitfaden der Psychiatrie.

Von Dr. Ph. JOLLY. Bonn: A. Marcus and E. Weber. 1914. Pp. 240. Price 4 marks.

To abstract satisfactorily psychiatrical conceptions is extraordinarily difficult, and the compendia and handbooks which result from attempts in this direction are very apt to stereotype in the mind of the student, even if he understands them at all, notions of insanity which he will be puzzled to coördinate with the cases he may meet in practice. Such works nevertheless have a value for examination purposes, and may be used to supplement and amplify lecture notes, while they may further serve the busy practitioner in good stead in the labelling of groups of symptoms. In the book before us we have a short recapitulation of general and special psychiatry in which almost everything seems to have been touched upon and with as much lucidity as space has permitted. The grouping of symptoms follows the current vogue, and would appear to be based upon the classification of Kraepelin.

The work is, we should think, quite likely to be of use to students and practitioners of German-speaking countries.

LIBRARY TABLE.

The Practitioner's Practical Prescriber. By D. M. MACDONALD, M.D. Aberd., Medical Officer of Health, Leven, Fife. London: Henry Frowde. 1913. Pp. 198. Price 5*s.*—This book is intended as a pocket formulary containing numerous hints and suggestions in regard to symptomatic treatment. In the first part diseases are considered in alphabetical order, and the treatment of each malady is briefly described, while the procedures recommended are trustworthy. For closer study naturally the larger text-books should be consulted. Diet tables, receipts for preparing invalid foods, and a short description of spas and climates suitable for certain affections are included. The few lines on "Tuberculin in Daily Practice" are to be regretted, and it would have been better to omit them altogether. Considerable experience is necessary for the proper administration of this remedy, and the suggestions here given are valueless. The book will be found useful for reference by the general practitioner.

The Transactions of the British Proctological Society for the Year 1913, with a List of Officers, &c. Edited by W. S. HANDLEY. London: Published for the Society by H. K. Lewis. 1914. Pp. 30. Price 2*s.* 6*d.* net.—This is perhaps the most exiguous volume of transactions ever published by any society. The prefatory note, however, explains the reason. The society was formed on Dec. 11th, 1912, and in July, 1913, it accepted the invitation of the Royal Society of Medicine to become a subsection of its Surgical Section. From that date on, therefore, the Proceedings of the society are continued in the Transactions of the Royal Society of Medicine. The present Transactions are of the same *format* and type, so that they will form one volume with their continuation from the Transactions of the Royal Society of Medicine. They contain the presidential address of Mr. Swinford Edwards, and papers on Four Cases of

Strangulated Hernia after Abdomino-Perineal Excision of Rectum, by C. Gordon Watson; X Ray Enemata in Diagnosis of Strictures of the Large Intestine, by Hamilton Drummond; Combined Excision of Carcinoma of Rectum Five Weeks after Operation, by W. Sampson Handley; Case of Kraske's Excision of Rectum followed by Two Ovariotomies, by Swinford Edwards; Secondary Growth in the Perianal Skin and Cellular Tissues Three Years after the Abdomino-Perineal Operation, by W. Ernest Miles; Adeno-Carcinomatous Tumour Primary in the Perianal Skin, by W. Ernest Miles; and a Case of Columnar-celled Carcinoma Arising in Track of a Fistula in Ano, by C. Gordon Watson.

Modern Problems of Biology. Lectures delivered at the University of Jena, December, 1912. By CHARLES SEDGWICK MINOT, LL.D., D.Sc., Director of the Anatomical Laboratories, Harvard Medical School. With 53 illustrations. Philadelphia: P. Blakiston's Son and Co. 1913. Pp. 124. Price $1.25 net.—These lectures, six in all, were written and published in German. In reviewing the German version in THE LANCET of May 24th, 1913, p. 1461, we stated that the author presented a very readable, instructive, and critical account of the subject, and we most heartily welcome the appearance in English of Dr. Minot's views on "immortality," death, sex, life, and the like, as set forth in these interesting lectures.

Les Nouveaux Horizons de la Science: La Matière Vivante, sa Chimie, sa Morphologie. Par H. GUILLEMINOT, Chef des Travaux de Physique Biologique à la Faculté de Médecine, Paris. Paris: G. Steinheil. 1914. Pp. 430. Price 6 francs.—It would appear that this is the third volume of the author's exposition of "The New Horizons of Science." Volumes I. and II. we have not seen. More than one-half of the text is taken up with a general and readable account of elementary and leading facts in organic chemistry, thermodynamics and other physical problems, catalysis and various chemical reactions. Book II. gives a similar account of the forms of living matter. Little is said about the functional aspects of the question. There does not appear to us to be anything very new or striking in the exposition of "The New Horizons of Science," at least to medical readers.

JOURNALS AND MAGAZINES.

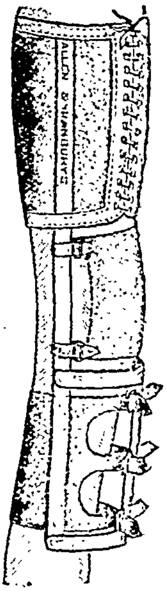
The Interstate Medical Journal. Special Tuberculosis Number. Vol. XXI. March, 1914. No. 3. St. Louis: The International Medical Journal Company. Subscription 10*s.* per annum, post free.—This is the first of two special numbers of the journal to be devoted to tuberculosis. The range of subject considered is so wide, and the specialisation of knowledge so minute, that no reader could fail to be impressed by the obvious gain of ground in the present day attack on the disease, though many will share the opinion openly expressed by several contributors that the optimistic statements of some British officials and politicians, which are fashionable at the moment, are erroneous and indiscreet. The articles fall chiefly under the headings of surgical treatment and chemiotherapy, though other aspects of the subject are reviewed. Professor Tuffier, of Paris, has a contribution indicating the value of the production of artificial pneumothorax for the immobilisation of excavated lung. The principle of artificial pneumothorax has been ascribed to Potain (1888), but Carson, of Liverpool, had advanced it in 1821, and it had been tentatively adopted by the late Mr. R. W. Parker, in London, years before that date. The technique has changed from the original injection of nitrogen or sterile air to operation by free opening and packing with fat grafts, Beck's bismuth paste, vaseline, and other materials. Kreuscher has been carrying out in J. B. Murphy's clinic a large series of injections of the pleural cavity with nitrogen, and the results have been very gratifying. The paper by Murphy and Kreuscher dealing with their technique is important and convincing. A short article by Carl Beck, of Chicago, on the bismuth paste treatment of sinuses can be strongly commended. The process is so simple that its use could be widely extended in ordinary practice. The value in "surgical" tuberculosis of sea air and sea water baths has long been recognised. Begun at Margate a century ago, the system of such marine hospitals spread in Italy in the "sixties." Only recently has it become apparent that sunlight is an important factor in these cures, and "heliotherapy," the continued use of direct sunlight on the naked body, is finding an increasing vogue for tuberculous joints and bones. It is obviously limited in geographical extent, as yet chiefly to the higher Swiss Alps and the shores of the Adriatic. Excellent results are secured at Leysin, above the Rhone Valley, in the sanatoria controlled by Dr. Rollier, and on the Lido, where efforts are being steadily pushed to lessen the appalling mass of tuberculous joints, which strikes every observant surgeon who visits Venice. It is noticeable in this review of American practice how little space is devoted to tuberculin, clearly because its employment is assumed. In the opinion of Dr. E. E. Myers, of New York, the value of the Piorkowski turtle tuberculin has been maintained on the ground of the slight reaction which it produces. An interesting note on the effects of infinitesimal doses of pure tuberculin ("endotin") in advanced cases comes from the pen of Dr. M. Solis Cohen, of Philadelphia. In all these cases the reagent was given by the mouth. Difficult as it is to award the palm to any one article of those before us, perhaps it should crown the essay emanating from the Sprague Institute of Chicago, inspired by Dr. H. Gideon Wells. The work of Ehrlich and his lieutenants has been so decisive that attempts to follow their lead must be made in the case of tubercle. But there is a basal difference in the discovery of a synthetic purifying poison in the three infections of syphilis, malaria, and tubercle, in that the two former are, at least in their early stages, infections of the blood and fluid tissues, whereas the tubercle bacillus tends very early to be shut off in the "tubercle" itself. Experimental work is complicated by two factors, one the non-vascularity of the tubercle, the other the impermeable structure of the tubercle bacillus itself, for it contains a large proportion of waxy and fatty material. Dr. Wells has therefore planned and carried out a preliminary and systematic investigation into the method of absorption by tuberculous tissues of various bodies, notably the iodine compounds, while lines of study are being followed by Miss Sherman and others in the dyes which affect fatty bodies. Suggested elements which are likely to provide effectively remedial salts are copper and gold. The quinine compounds, especially ethyl-hydrocuprein, employed by Morgenroth, one of Professor Ehrlich's assistants, have given good curative and better prophylactic effects in tuberculous mice, but the scope of employment as applied to human subjects has been scanty and disappointing, while in three instances out of 23 a severe but transient amblyopia has followed the injections. There are several curious articles on the psychic changes wrought by absorption of tuberculous products, of which the most remarkable is a short study of the mental attributes of Francis Thompson, the unfortunate author of "The City of Dreadful Night," attributes which contrast strongly with the phrase first used by a great American writer years ago, the "tubercular virtues."

Jahreskurse für Aerztliche Fortbildung. Munich: Lehmann. Subscription price, 18 marks.—The issue for February includes the following. Professor Hoffmann writes a review of recent study on the pulse, the effect of variations in age, respiration, and pathological states, and the various means of obtaining records, including, besides the older and well-known instruments, the sphygmobolometer of Sahli, a figure of which is given. This consists of a mercury manometer, an air manometer, and a rubber ball, all capable of inflation by a syringe, and by its means the volume of the pulse as well as the blood pressure can be measured. (The instrument is made by Buchi and Son, Berne.) The value of pulse records in diagnosis and treatment is also considered. The same writer furnishes an article on digitalis therapy, with some discussion of the numerous preparations of the drug now on the market. The indications and contraindications are also mentioned.—Professor Staehelin writes on the various forms of cough and their diagnostic significance, pointing out how the character of the cough may be a guide to the diagnosis of its cause. He then proceeds to discuss the treatment by expectorants, sedatives, and other drugs. A general review follows, giving a few lines to each of the numerous publications of the past year or two in Germany dealing with diseases of circulation and respiration.—The March number opens with a discussion of the significance of ulceration and bleeding in the alimentary canal associated with diseases of the heart and arteries, by Professor Fleiner. Simple or malignant endocarditis, arterio-sclerosis, or syphilitic aortitis may all be causes of bowel hæmorrhage by giving rise to embolism or thrombosis, and illustrative cases are described in which gastric or duodenal ulceration was due to this.—Professor Jacoby gives some account of Abderhalden's methods of blood examination for the diagnosis of pregnancy, and Professor Schade describes the application of the methods of physico-chemical analysis to the blood serum; in particular the measurement of the quantity of free H or OH ions by electrical and other methods, which is of value, for instance, in the study of acidosis. The viscosity of the blood may also be measured by the apparatus figured and described; it is raised by work, venosity, and inflammatory processes, and falls in anæmia.—Professor Erich Meyer writes on the anæmias in general and pernicious anæmia in particular, passing in review the blood-picture and pathology and the newer methods of treatment, such as the salvarsan preparations, thorium rays, X rays, and other therapeutic agents.

The Military Surgeon. Published monthly by the Association of Military Surgeons of the U.S.A. Editor: S. O. STANTON, Brigadier-General. Chicago. Price 1*s.* 6*d.* per copy; 15*s.* per annum.—The first article of the April number is a warm appreciation by Dr. L. Webster Fox of the operation of Lieutenant-Colonel R. H. Elliot, I.M.S., for chronic glaucoma (THE LANCET, March 21st, p. 808). Dr. Fox in his own operating-room in Philadelphia had had eight cases operated upon by Colonel Elliot during that officer's recent visit to the United States. Dr. Fox expresses the opinion that at the International Medical Congress last August, in the section of ophthalmology, the two men most conspicuous were Professor Lagrange, of Bordeaux, and Colonel Elliot.—Captain Louis H. Schultz had a curious experience once when in charge of a sanatorium. He discharged for misconduct a patient with advanced phthisis (much sputum, many bacilli), but the man turned up again in a few days, this time as a visitor and in the uniform of the United States army. Such a recruit is a great danger to a regiment, so Dr. Schultz proposes to send all recruits for two weeks to a quarantine station for minute examination (X ray examination of chest, Wassermann test, blood counts, &c.), and for observation in case he is incubating an infectious disease. He notes that cases of early phthisis generally show deficient expansion, thus bearing witness to the sagacity of the British Army Medical Department which lays stress on just this measurement.—Captain Schmitter, in charge of a leper hospital at Manila, gives reasons for his belief that leprosy may be a symbiosis of the bacillus lepræ with the treponemata of syphilis or yaws.—Lieutenant W. B. Meister tells of a new danger to the United States army—cocainism. The pure crystals are taken as snuff; about $\frac{1}{8}$ grain eight times repeated produces the desired "dream." A patient becomes facile, loses reliability, promptness, and punctuality, is unfit for sustained exertion, and falls out even from a short practice march. There is a sign; the nares are apt to be blanched immediately after a dose, but congested and swollen later. Treatment is of no lasting avail. This drug habit is assuredly causing much trouble in North America.—Lieutenant-Colonel Jacob Frank, of Chicago, Surgeon-General of the Illinois National Guard, recommends a new first aid for wounds of the abdomen, as the outcome of interesting observations in civil practice, and many experiments on dogs. He desires that no penetrating wound of the abdomen shall be treated by putting the first field dressing over it, to dam back the intestinal leakage and force it to infect the whole peritoneal cavity. On the contrary, he wishes everyone taught to push a little of the first-aid packets gauze into the wound with a stick (a match for example) to serve as a drain and so give the peritoneum a chance to remain clean. An important paper all should read.—There is an editorial on the work of the United States Public Health Service, giving it deserved credit for awakening a sanitary conscience in the various States, and asking for it stronger financial support so that it can increase its usefulness. We observe that a surgeon has been detailed to give two lectures on tuberculosis to the Farmers' Conference at Savannah, Georgia, at the request of the Georgia State Agricultural College.

New Inventions.

AN EXTENSOR KNEE SPLINT.



I HAVE described elsewhere[1] an apparatus for the reduction of flexural deformities at the knee-joint when actual bony ankylosis is not present. After the reduction of such deformities or in the course of the disease which tends to produce them a knee splint with a slight extensor action is required. The illustration here reproduced shows such an apparatus. I have used it chiefly in some period of the treatment of cases of tuberculous knee. It consists of a leather sheath which is laced on to the thigh; from this two lateral steel struts extend directly downward to a level just above the ankle. These two side steels are united across the front of the leg by two U-shaped arches. The vertices of the arches are united by a metal bridge, and over this is buckled an elastic sling which passes behind the leg. In accordance with the tension on the elastic sling the extensor action at the knee-joint can be modified. A soft leather cap passes from the side irons across the front of the knee to take the backward pull. The splint is kept in place by means of a strap attached to a pelvic band or passing over the opposite shoulder. The apparatus can also be applied as an integral part of a hip-splint. The thigh piece should fit with accuracy, and care must be taken that the knee-cap bears evenly over the patella.

The apparatus has been made for me by Messrs. Allen and Hanburys, Wigmore-street, London, W.

Welbeck-street, W.

---

[1] Proceedings of the Royal Society of Medicine, Surgical Section, January, 1914, p. 113.

AFTER-CARE ASSOCIATION.—The annual report of the council of this association for the year 1913 shows that applications on behalf of 377 persons were received, of whom 228 were women and 149 men. Of the total number of cases 106 were from the London county asylums, 197 from other county and borough asylums, 18 from mental hospitals and licensed houses, and 56 from various institutions or from private sources. Of these, 119 had been assisted in various ways during previous years and 258 were first applications. The important work of assisting poor persons discharged recovered from asylums for the insane is now being extended by helping cases discharged on trial. During the past year 11 such cases have been satisfactorily dealt with, but the extension of work considerably adds to the financial burdens of an association which is doing good work and which therefore deserves support and encouragement. It is the only charity of its kind in the United Kingdom, and cases are assisted from all parts of the country. Although, owing to legacies, the total receipts have increased, the annual subscriptions and donations have decreased, and new contributions are urgently needed. An annual subscription of 5*s.* constitutes the subscriber an ordinary member, while a single gift of £5 makes a life member. The address of the Association is Church House, Dean's-yard, Westminster, S.W., and the bankers are the Union of London and Smith's Banks Victoria-street branch), Westminster.

Leitz

MICROSCOPES

are well known for
EXCELLENCE OF WORKMANSHIP,
EASE OF MANIPULATION,
and MODERATE COST.

THE NEW AND IMPROVED MODELS

possess many advantages over the older type, and embody several important features not to be found in any others. The mechanical features in the new models, combined with the high quality of the recently improved objectives, place the Leitz Microscopes in an UNRIVALLED POSITION.

Prices, with Optical Equipment, from £6 : 10 : 0.

H. K. LEWIS'S PUBLICATIONS.

JUST PUBLISHED. FIFTH Edition, Revised and Enlarged. With Illustrations. Demy 8vo. Price 10s. 6d. net; post free, 10s. 11d., abroad, 11s. 4d.

ANÆSTHETICS; their Uses and Administration.

By **DUDLEY W. BUXTON**, M.D., B.S., M.R.C.P., Administrator of Anæsthetics and Lecturer in University College Hospital; Consulting Anæsthetist to the National Hospital for Paralysis and Epilepsy, Queen Square; Senior Anæsthetist and Lecturer on Anæsthetics in the Royal Dental Hospital of London, &c. [*Lewis's Practical Series.*

NOW READY. SIXTH Edition, thoroughly Revised. With 14 Plates and 175 Illustrations. Demy 8vo, 12s. 6d. net; post free, 12s. 11d., abroad, 13s. 6d.

MEDICAL ELECTRICITY:

A Practical Handbook for Students and Practitioners.

By **H. LEWIS JONES**, M.A., M.D., F.R.C.P., Consulting Medical Officer to the Electrical Department in St. Bartholomew's Hospital; Honorary Fellow of the American Electro-therapeutic Association; Member of the Société Française d'Electrotherapie et de Radiologie. [*Lewis's Practical Series.*

"All who wish to keep thoroughly up-to-date in their knowledge should provide themselves with the new issue."—THE LANCET.

"The standard work which should be consulted by all medical practitioners who employ electricity in the treatment of disease."—MEDICAL PRESS.

NOW READY. SECOND Edition. BY THE SAME AUTHOR. With Coloured Frontispiece. Crown 8vo, 5s. net; post free, 5s. 3d., abroad, 5s. 4d.

IONIC MEDICATION.

The Principles of the Method and an Account of the Clinical Results Obtained.

"The book so distinctly fills a vacant place that we are not surprised to hear that it has already reached a second edition"—BRITISH MEDICAL JOURNAL.

SEVENTH Edition. Thoroughly Revised and Enlarged.
258 Text Illustrations and 18 Plates (13 in Colour). Demy 8vo, 12s. 6d. net; post free, 12s. 11d., abroad, 13s. 6d.

THE DISEASES OF WOMEN. A Practical Handbook.

By **ARTHUR H. N. LEWERS**, M.D.Lond., F.R.C.P.Lond., Consulting Obstetric Physician to the London Hospital; late Examiner in Midwifery and Diseases of Women at the Conjoint Board of the Royal College of Physicians of London and of the Royal College of Surgeons of England, &c. [*Lewis's Practical Series.*

"A good and sound text-book for the student."—THE LANCET.

"We welcome with pleasure this new edition ...... we can truly say that there are few books of its age dealing with the same subject that so well deserve a place in the library of the student of the present time."—MEDICAL PRESS.

TENTH Edition. Thoroughly Revised. Crown 8vo, 9s. net; post free, 9s. 4d., abroad, 9s. 10d.

ELEMENTS OF PRACTICAL MEDICINE.

By **ALFRED H. CARTER**, M.D., M.Sc., F.R.C.P.Lond., formerly Professor of Medicine, University of Birmingham; Emeritus Prof. of Physiology, Queen's College, Birmingham; Consulting Physician to the Queen's Hospital, Birmingham, &c.

"We congratulate the distinguished author on the appearance of the tenth edition of a work which has been so successful as to prove acceptable for nearly one-third of a century. ...... The favourable criticisms that have been expressed concerning previous editions may be confidently reiterated concerning this tenth issue. The book has been carefully revised and many chapters re-written."—BRIT. MED. JOURNAL.

NOW READY. FIFTH Edition. Thoroughly Revised With 2 Plates and 92 Illustrations. Demy 8vo, 12s. 6d. net; post free, 13s., abroad, 13s. 6d.

HYGIENE AND PUBLIC HEALTH.

By **LOUIS C. PARKES**, M.D., D.P.H. Lond. Univ., Consulting Sanitary Adviser to H.M. Office of Works; Examiner in Public Health to the Royal Colleges of Physicians and Surgeons, London, &c; and **HENRY R. KENWOOD**, M.B. Edin., D.P.H., F.C.S., Examiner in Public Health to the Royal Colleges of Physicians and Surgeons, London, &c.; Chadwick Professor of Hygiene in the University of London, &c. [*Lewis's Practical Series.*

"The edition deserves, and is certain to receive, fully as much favour as its forerunners."—THE LANCET.

FIFTH Edition. Thoroughly Revised. With 96 Illustrations. Demy 8vo. 10s. net; post free, 10s. 5d., abroad, 11s.

Public Health Laboratory Work.

By **H. R. KENWOOD**, M.B., D.P.H., F.C.S., Chadwick Professor of Hygiene in the University of London; Medical Officer of Health and Public Analyst of Stoke Newington, &c. The part on Bacteriological Work is contributed by **W. G. SAVAGE**, M.D., B.Sc., D.P.H., &c. [*Lewis's Practical Series.*

"Indispensable to all interested in the science of Public Health."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

NOW READY. SEVENTH Edition, thoroughly Revised and Enlarged. With numerous Illustrations. Cr. 8vo, 3s. 6d. net; post free, 3s. 9d.

Massage and the Original Swedish Movements;

their Application to various Diseases of the Body. By **KURRE W. OSTROM**, Royal University of Upsala.

"*Mr. Ostrom's useful little book.*"—THE LANCET.

NOW READY. 624 pp. 126 Engravings and 15 Plates. Medium 8vo. 25s. net; inland postage, 7d.

Diseases of the Stomach, including DIETETIC and MEDICINAL TREATMENT.

By **G. R. LOCKWOOD**, M.D., *Professor of Clinical Medicine in the Columbia University.*

"He has certainly succeeded in giving a full account of his subject."—BRITISH MEDICAL JOURNAL.

"*The book is written* in a clear manner, and the illustrations are excellent."—THE LANCET.

Reform of the Public Health Service.

ONE of the most urgent matters which must engage the attention of Mr. HERBERT SAMUEL as President of the Local Government Board is the question of reforms in the administration of the Public Health laws. The administrative machinery was designed, much of it, 50 years ago, and it can hardly be said to have been really overhauled in any effective manner. The Local Government Board with its limited and ineffectual compulsory powers is the central public health authority, and it is still left to local sanitary authorities to decide whether or not the various Public Health and Housing Acts shall be carried out. It is true that the creation of county councils in 1888 brought into existence an authority with executive powers which could be used in case of default by the district councils, but these powers have been only rarely exercised. County Councils undertake public health duties specifically given to them with excellent results, but they are rightly reluctant to coerce other authorities in matters for which the county has no primary responsibility. While the administrative machinery has remained unaltered for half a century, the claims upon it have been increased to so great an extent that it is quite right to inquire whether the time has not arrived when suitable modifications and adjustments should be made in order to enable it to fulfil the requirements of the present day.

If the position of the medical officer of health to-day is compared with that of 50 years ago it will be recognised that his work and responsibilities have been very considerably enlarged. The Royal Sanitary Commission suggested in 1871 that the principal duties of a medical officer of health should be to study and report to the central office as well as to his own local authority, and this with dispatch, all things relating to considerable changes in the health of his district, and to collect from certain sources material which might be combined with his own observations in general reports on the health of the district, together with his recommendations. It was evidently intended by the Commissioners that the medical officer of health should be essentially an advisory officer and that he should have few executive duties; indeed, it was recommended by them that he should obtain at the offices of the local authority assistance in the clerical work entailed in making his reports and statistical returns. It is expected, however, to-day that the medical officer of health should be the executive head of a public health department, and he has not only to advise what steps should be taken to carry out the Public Health Acts, but he is responsible for the taking of those steps. These executive duties have very considerably altered the position of the medical officer of health in relation to the local authority. As an advisory officer and nothing more he made general recommendations as to water-supplies, drainage schemes, the adoption of by-laws or regulations, and similar matters, and his recommendations were addressed to the authority as a body. But as an executive officer he has to deal with individuals who may be property owners, dairymen, butchers, or other tradesmen. These again are frequently members of the local authority, and they resent having to carry out the requirements of an official whom they look upon as their servant, and who holds office only as long as he receives their support. This being so, it is of the utmost importance that the medical officer of health should not be dependent upon the members of local authorities for his continuance in office, or solely dependent on them to get the increase of salary which is necessary if the new executive duties are to be carried out.

The Royal Commission to which reference has already been made was quite alive to the necessity for securing the independence of the medical officer of health, even though his duties were to be mainly advisory, for it made the definite recommendation that in order that medical officers of health might be able to discharge their duties without fear of personal loss they should not be removable from office by any local authority, except with the sanction of the central authority. This recommendation has been endorsed over and over again by other Commissions and Government Committees. In the first volume of the Land Inquiry Committee, which was issued last year, it is stated that one of the consequences of the insecurity of tenure of medical officers of health in rural districts is that they are often afraid of offending district councillors and the better-class inhabitants who are the owners of property. In justice to medical officers of health it should be said that they frequently take the indicated risk, but it is not fair that they should be asked to do so. The very precise statement is made by the Land Inquiry Committee that the Housing Acts will not be properly enforced until medical officers of health obtain a greater security of tenure. The committee makes a similar reference in the more recently issued second volume which relates to urban districts, and recommends that except in cases of gross misconduct a local authority should be obliged to obtain the sanction of the Local Government Board before dismissing a medical officer of health or sanitary inspector, and that the payment of adequate salaries to those officers, in accordance with a schedule to be provided by the central authority, should be made a statutory obligation upon local authorities. When the Housing and Town Planning Bill, 1909, was before Parliament opportunity was taken to obtain for county medical officers of health security of tenure of office, subject to approval by the Local Government Board, and as there is a probability of a Government Bill with respect to housing in rural districts being introduced in the present session it is to be hoped that advantage will be taken of this measure to give a similar security to all medical officers of health, and to prevent them from being starved by inches as the result of Government departments continually multiplying their duties without increasing the pay of their office.

Art and Medicine.

THE artist of all sorts—painter, sculptor, engraver, and jeweller—has portrayed medical events in the manner dictated by his respective calling and has done so from very early times, for some of our most ancient discoveries in sculpture and pottery have borne representations of various pathological conditions. Mr. HASTINGS GILFORD, in one of his recent Hunterian lectures delivered before the Royal College of Surgeons of England,[1] called attention to prehistoric drawings of the human figure displaying various physiological and pathological conditions; and one of these outline sketches from the rock sculptures in the Dordogne was at least 15,000 to 20,000 years old in the opinion of experts. There is one remarkably different result for us of to-day from the labours of the artist, contrasted with the result derived from the writings of numerous authors who have described medical events in general literature. It is this. The artificers have very usually shed definite light on medicine, while the chroniclers, poets, and dramatists, though dealing freely with medical topics, have not been as distinctly informatory. Written descriptions of diseases occurring in general literature in great measure leave doubtful diagnoses for the reader to choose between; pictorial representations have often been equivalent to accurate naming of the conditions. Historians have touched upon epidemics in accounting for the social and political conditions of the nations in whom they are concerned, but as often as not it remains a matter of doubtful inference from their words under what particular pest the people were supposed to be abiding. Malaria appears to have been described in classic Greek literature, and in the Bible there are accounts of some epidemics the nature of which we can identify. But there are other pestilences which conform equally to any of two or three diseases, and leave the searcher for accuracy considerably puzzled. The epidemic to appear in most obvious guise upon the stage of history is plague, but it is quite likely that many chroniclers have confused leprosy with it and with syphilis. What, again, was the English Sweat? Although the great Caius wrote a "Boke or Conseill against the disease commonly called the Sweate or Sweatyng Sicknesse," we do not obtain a description from which a diagnosis can be made for certain, and with some doubt decide to think that this mysterious illness was influenza.[2]

Of course, medicine has a very definite literature of its own, in which it has been for many generations the mission and pleasure of learned men to describe the origins, course, and therapeutics of disease. Of this learning enshrined for the information of scientific men generally, or of practitioners of medicine in particular, much is splendidly written, nor do such books lack what for purpose of definition has been described as the essential principle of literature—namely, universal appeal. All are interested in their teachings, though expert intervention is required to transmute the theories into practice. The most authoritative of these books belong to the class which DE QUINCEY called "the literature of knowledge" as distinguished from "the literature of power," for each of them must remain upon trial for ever: "Let its teaching be even partially refuted," said DE QUINCEY, "let it be expanded, nay, even let the teaching be placed in a better order, and instantly it is superseded." In the literature of medicine proper there are word pictures of disease every whit as accurate as brush, pencil, or chisel could make them, but these descriptions cannot be detached from the treatises in which they occur, and the significance of the symptoms detailed has altered and keeps altering with our progress in pathological learning, until the value of the words employed grows less and less. The great SYDENHAM omitted to mention sore-throat as a symptom of scarlet fever; other descriptions, laying more stress upon inflammation of the pharynx or larynx, were possibly accounts of diphtheria, whether called scarlet fever, "confluent measles" or "putrid sore-throat." The artist seldom produces similar confusion: in such diseases and deformities as he represents he usually gives the salient features in such a way that no one can fail to diagnose the condition intended. RUBENS saw a girl in a hysterical paroxysm, and once and for all has revealed to us what was the real meaning of the cases of demoniac possession which were a marked feature of mediæval life. Nothing that ever can happen in the development of medicine will alter the truth told in the famous picture of St. Ignatius's miracle, while we know from the portraits of dwarfs, in which VELASQUEZ revelled, the types of infantilism which were prevalent in the seventeenth century. Dr. PAUL RICHER in his excellent book, "L'Art et la Médecine," gives many reproductions of pictures and sculpture showing how faithful artists have been in their delineation of such diseases as leprosy, syphilis, plague, and rickets. Historians have described these conditions with pains, and medical literature has referred to them with particularity, but in the written accounts stress is so easily laid upon other than essential things that for the purposes of diagnosis the artist generally gives us the larger help.

[1] THE LANCET, March 7th, 1914, p. 663.

[2] W. H. Hamer: The Milroy Lectures on Epidemic Disease in England, THE LANCET, March 3rd, 1906.

There is a pictorial art associated with medicine; the allusion is to the illustrations, often beautiful as well as accurate, which accompany treatises on anatomy, physiology, and medicine, and to the charts, maps, and pictorial diagrams intended to be hung in lecture halls for the instruction of students and the assistance of teachers. To this category of artistic productions belong many admirable albums illustrating surface lesions, many adroit wax models, and some large oil paintings of strictly pathological conditions. We reproduced recently in the columns of THE LANCET[1] some famous panels of this sort by JACQUES GAUTIER D'AGOTY. The anatomical exactness was here accompanied with beautiful drawing and painting. But the help in the recognition of symptoms that medicine has received from bygone art will not be continued to our successors in the same way. Photography and its mechanical reproductions, colour printing, and the cinematograph have entirely removed such paintings from the sphere of practical utility; while the pathological subject is in the nature of things not likely to be the pre-eminent favourite with great artists that it was in the Middle Ages. To the old masters the Bible and the lives of the saints were the source of inspiration, and representations of pestilences, martyrdoms, and miraculous healings were the ever-recurring themes. To-day the pathological subject is left severely alone. Future generations will learn nothing of disease and nothing of the practice of medicine from the exhibition of the Royal Academy of Arts which is opened to the public this week, and which contains a more than usually interesting number of paintings and sculptured work. Medicine is mainly represented by portraits of medical men, and even here the distinctive marks of their calling are generally absent. A strong and simple portrait of Sir WILLIAM TURNER, by Sir JAMES GUTHRIE, renders the Principal of Edinburgh University in robes with orders on, and the late Sir HUBERT HERKOMER depicts Sir LAUDER BRUNTON very adroitly and sympathetically in something approaching fancy dress: but Professor WILLIAM BULLOCH is shown by Sir LUKE FILDES'S careful and academic brush in the clothes of the man in the street. Sir WILLIAM RICHMOND paints a masterly head of Dr. J. S. HARVEY, where the Rembrandtesque treatment suggests no medical trappings, and Mr. COPNALL'S successful portrait of Dr. H. BRIGGS might be that of any cultivated man. These pictures have no particular message in regard to medicine similar to that which the numerous pictures of soldiers, ecclesiastics, and officials, appropriately garbed, may have for a future generation; or rather they may be considered to give the true message that medical priestcraft has no longer any existence.

Annotations.

"Ne quid nimis."

THE STATUS OF MENTAL NURSES.

THE spectacular character of the vast advances in surgery during the past half century could not fail to lead to a general recognition of them. The less spectacular but also very great advance in medical science is, if less generally, also realised. And with the realisation of this progress has naturally come about also a comprehension of the importance of the part played by nursing in the relief of suffering, and consequently an appreciation of the necessity for adequate training for nurses, and of what is due in the way of enhanced status and remuneration for the exacting but beneficent duties of the nurse. There is one division of medicine, however, in which the progress made is taken too much as a matter of course by a people who can hardly remember the conditions previous to the reorganisation of our therapeutics. We refer to the changed conceptions of mental disorders and the changed methods of dealing with them that are the consequence thereof. It is now so fully recognised that these disorders are as truly diseases as any whose seat of origin in the physical organism is clearly recognisable, that we do not realise that the insane were once confined in strait waistcoats, in dark cells bedded only with straw, flogged to subdue maniacal excitement, and subjected to the tender mercies of "keepers" often drawn from the dregs of the people. And even yet the public mind is not fully awake to the fact that the nursing of the insane on modern lines requires in the nurses a very high degree of all the personal qualifications and technical training that we have come to regard as indispensable in the general medical and surgical nurse. It is gratifying to learn, therefore, that the Nursing Conference held this week in London set apart a special sitting to discuss the status and work of mental nurses, which have hitherto received very inadequate recognition. In an impressive address Dr. Robert Armstrong-Jones, resident physician to the London County Asylum, Claybury, estimates that there are some 140,000 mentally afflicted persons in England and Wales alone, and that in caring for them some 20,000 persons are engaged, whose duties are the most difficult, as well as the most responsible and trying, that any man or woman may be called on to perform. These duties are often carried on in out-of-the-way and little-known places, and the qualities demanded by them are self-discipline and tact of the highest conceivable degree. The mental nurse, while requiring special education, must have a thoroughly efficient training in general sick nursing also. This will be at once evident when it is realised that last year 14,000 persons died in the asylums of England and Wales from causes representing nearly all the ordinary diseases and conditions met with in general hospitals and private practice—tuberculosis, diseases of all the internal organs and the nervous system, and special conditions connected with the puerperium and lactation, with senility and the climacteric. The mental nurse may have to prepare for, and assist at, major operations, to nurse typhoid or scarlet fever patients, and to watch the effect and record the result of long-continued administration of special remedies. Moreover, special difficulties occur in consequence of the great liability to bedsores of the bedridden insane, and Dr. Armstrong-Jones rightly says that it is a triumphant testimony to good nursing that at the Claybury Asylum, with an average resident population of 2500 insane persons, there is not now a single case of bedsore, nor has there been one for over a year in the male wards or for several years in the female wards. Dr. Armstrong-Jones commends the scheme of instruction for mental nurses, due to the initiative of the Medico-Psychological Association, which grants a certificate on satisfactory examination after a three years' course of training; this is so far appreciated that most asylum authorities grant a special monetary allowance to its holders. The effort for good training has received every encouragement from the Lunacy Commissioners. Dr. Armstrong-Jones strongly supports the claim for the registration of these certificate holders, which has been previously urged by a Select Committee of the House of Commons, the General Medical Council, and the British Medical Association, and he mentions that it is due to the efforts of Sir William J. Collins, while in Parliament, that workers in asylums are now provided for in their old age. The London County Council, too, has recently raised the rate of remuneration, and most asylum authorities have realised the importance of granting their nurses adequate leave and rest. As the result of his observations in foreign asylums Dr. Armstrong-Jones eulogises the work of religious orders as involving a very lofty ideal, for, he says, if behind the unobtrusive devotion to practical ideal there is a strong force of religious feeling, a driving power exists which cannot be rivalled. The reorganised St. Katharine's Royal Hospital, also, is commencing a crusade of preventive work by the appointment of health visitors, and he very properly expresses the hope that the prevention of mental diseases will be included in the scope of its work by the appointment of asylum nurses.

---

[1] THE LANCET, Feb. 21st, 1914, p. 557.

WORK AS A THERAPEUTIC AGENT.

THE therapeutic use of rest has long been insisted upon in certain acute conditions; the equal value of work, properly adjusted and carefully supervised, in other classes of disease has received less attention. To be sure, graduated labour in tuberculosis has had consideration, and the value of occupation has been generally recognised in mental disturbance. We all know that there is nothing like work, particularly physical exertion, to overcome the "blues" or to distract the mind during great trouble, but there is room for a more general study of the systematic organisation of work as a therapeutic measure for the mentally unsound. From an interesting article in a recent number of *La Semana Medica*[1] on Work as a Therapeutic Means in the Treatment of Mental Diseases, by Dr. Fernando Gorriti, physician to the Colonia Nacional de Alienados, an asylum for the insane, we learn that work, carefully regulated in accordance with the needs of the individual patient, is used as a means of treatment in a large proportion of the cases admitted. The great majority of the patients in the Colonia are drafted into that institution from the vast Hospicio de las Mercedes in Buenos Aires, whose director, Professor Cabred, who is also the founder, organiser, and director of the Colonia, periodically transfers thither such of the patients in the Hospicio as he considers likely to derive therapeutic benefit from systematised work. On arrival at the Colonia the patient's case is carefully considered afresh, his present condition is investigated, and due weight is given to the notes of his case sent on with him from the Hospicio. The work of selection is thus continued, special care being taken to ascertain whether the patient suffers from any delusion likely to make him dangerous to others or to himself, in which case he is drafted to one of the sections in which patients are under constant observation, to be placed there under appropriate medical treatment until fit for work, or, in the opposite event, to remain there indefinitely. Should the patient be considered fit for work, and should it appear from the notes of his case that before his illness he followed some definite occupation—*e.g.*, that of a carpenter, cobbler, tailor, plumber, mason, or what not—he is put to work at it under expert direction. Should he have had no occupation he is, as a rule, put to outdoor work of some kind, such as farming, gardening, care of poultry, cattle, pigs, or sheep. The patients are constantly visited by the physician while at work so that he may note their general progress and regulate the hours of work (which in no case exceed seven per diem) in accordance with individual requirements. Dr. Gorriti speaks in the highest terms of the results of this systematised work in the treatment of insane patients. He enumerates some of the chief benefits of the method as follows: 1. A diminution of agitation and motor excitability with a corresponding improvement in the patients' sleep, which becomes quiet and restful and longer in duration. 2. A postponement in chronic cases or a complete escape from the onset of a condition of total dementia. This Dr. Gorriti ascribes to the beneficial action of the slight intellectual exercise involved in the occupation followed. 3. A return of the power to work, the importance of which, especially when there is added to it a practised acquaintance with some definite occupation, can hardly be over-estimated in the case of patients sufficiently recovered to leave the asylum or return to active life.

HOAXING AN EDITOR.

ONE of the Berlin daily papers which is antagonistic to scientific medicine and advocates the so-called "natural" methods of treatment, Christian science, antivaccination, and other unorthodox procedures, has lately been the object of an unkind practical joke. A correspondent wrote to the editor to say that at the last Congress of Internal Medicine one of the greatest medical authorities—His Excellency Privy Councillor Professor Dr. von Rutan—had read a paper which caused a very great sensation owing to the fact that the celebrated professor had stated that modern medicine was a humbug, and that all the great discoveries had been made by laymen, such as Pastor Kneipp and Priessnitz, and that he had decided for the future to take no part in the fraudulent pretensions of allopathic medicine to which he had hitherto adhered. The editor of the journal remarked that he had no intention of expressing a decided opinion in reference to a matter regarding which the medical profession was not unanimous, although the views of a man in such a position as His Excellency Professor Dr. Rutan deserved careful consideration. He only wished to draw attention to the fact that presumably the medical organs had conspired together to exclude any report of that important address which was not found in any medical journal, and that this had been obviously done by order or on behalf of the president of the congress. A kind of terrorism, he said, existed to-day in scientific medicine, and by a common agreement the opinions of opponents of allopathic treatment were never mentioned in the medical journals, a procedure which was a public scandal. This editorial effusion caused much amusement in medical circles, because the journal had always been hostile to the medical profession, and the editor was invited by some journalists to read the name of the celebrated professor backwards, when it appeared that the name Rutan was merely an inversion of the word "Natur."

---

[1] La Semana Medica, Buenos Aires, Feb. 12th, 1914.

THE SPREAD OF TUBERCULOSIS VIEWED FROM THE LABORATORY AND FROM THE EPIDEMIOLOGICAL STANDPOINTS.

AN interesting comparison between conclusions drawn from laboratory evidence and others based on an epidemiological examination of families in regard to the spread of tuberculosis is made in the United States Public Health Reports for Feb. 20th. In April, 1913, Dr. E. R. Baldwin, of Saranac Lake, New York, a pioneer station of the scientific study of tuberculosis, as the result of an analytical study of the experimental work done on immunity and the susceptibility of a once-infected animal to superinfection or reinfection, laid down, as "reasonably sure conclusions," that most adults have received some tuberculosis infection, thus acquiring a variable degree of specific allergy. It would follow that during ordinary health the tissues would repel tubercle bacilli partly by this aid; that reinfection is mostly autogenous superinfection and is due to disease, overstrain, trauma, or lowered vitality; and that consequently adults are very little endangered by close contact with open tuberculosis, and not at all by ordinary association. "Childhood," he said, "is the time of infection, youth the time of superinfection and that from the extension of the primary disease." Dr. Baldwin's purpose was to allay a grossly exaggerated phthisiophobia by contrasting the relatively slight danger of infection in adult life as compared with that in childhood. On the other hand, a study of the spread of tuberculosis in families, by Herbert G. Lampson, made in Minneapolis under the supervision of a committee, was published in December, 1913, as a bulletin of the University of Minneapolis. Lampson examined with the tuberculin test 173 individuals in 33 families containing open cases of pulmonary tuberculosis. Of these 124 showed evidence of infection, 41 no evidence, 8 were doubtful. Of the doubtful cases one has since been declared tuberculous, and one has had a pulmonary hæmorrhage. Deducting the 23 centre cases yet living from the 124 infected, 101 individuals, or 67 per cent., were presumably infected from the 33 centre cases. In four families with latent centre cases, out of 22 individuals examined 8 showed tuberculous infection, 3 were suspicious—deducting the 4 centre cases, an infection of 22 per cent. of individuals exposed. In three families with healed centre cases, of 12 individuals examined 6 were infected, or, deducting the 3 centre cases, 33 per cent. In ten families "classed as containing non-tuberculous centre cases," out of 56 individuals examined 1 showed tuberculous infection and 2 were suspicious —1·7 per cent. of all individuals in the household. In five control families containing no suspected cases of tuberculosis, out of 24 individuals examined, 1, or 4·1 per cent., showed evidence of infection. To sum up, a comparative test was thus made in 40 tuberculous families representing 207 individuals, of whom 138, or 66⅔ per cent., showed tuberculosis, and 15 non-tuberculous families representing 80 individuals, of whom 2 showed tuberculosis and 2 were suspicious—i.e., 2½ per cent. Of the 40 families 10, containing 54 individuals, showed tuberculosis in every individual. From these data Lampson concludes that the spread of infection in families having open cases of tuberculosis is greater than is generally believed; that in families where no case of tuberculosis has been found evidence of tuberculous infection was only 2½ per cent., and that the spread of infection is not so great in families with merely latent infection, or with healed cases, as in those with open cases. While, therefore, agreeing with Dr. Baldwin that phthisiophobia is to be strongly deprecated, it would seem as though epidemiological evidence must so far prevail as to resist very strongly any slackening of vigilance against the spread of infection from one human being to another.

THE INSANITARY CONDITION OF DARTMOUTH.

A STRONG indictment of the sanitary condition and management of this historical and picturesque Devonshire town appears in a recently issued report to the Local Government Board by Dr. F. St. George Mivart.[1] Its older houses, which at first sight seem externally to be of a substantial character and reasonably habitable, appear on closer examination often to be built with their backs against the earth, badly lit and ventilated, and with abundant dilapidations. They have long fallen out of fashion and have become subdivided into tenements made without any regard to the requirements of healthy dwellings. Even on bright sunny days the gloom of many of these places is described as oppressive; in the winter it must often be impossible for inmates to carry on any sort of work without artificial light. Inner rooms are partitioned off and used for sleeping which have only borrowed light, and windows are often fixed shut. All kinds of dilapidation and neglect were observed in the condition of the common stairways, passages, and yards. The occupants are described as dirty and careless in habits; on the other hand, as Dr. Mivart observes, it is difficult to see how they could be otherwise in such surroundings. The town water-supply comes from a number of different local sources, some of which are open to considerable suspicion of pollution, and the waterworks management and such methods of filtration as are employed were found quite unreliable. House refuse when collected is dumped, pending removal, in a stoneyard adjoining the quay, where the ground is fouled, attracting swarms of flies. Most of the bakehouses were found in a disgraceful condition, and from the facts stated in the inspector's report his conclusion that their state constitutes a scandal appears fully justified. The milk-supply is obtained from insanitary cowsheds.

and the institution represented as an isolation hospital "seems of little value in its present fragmentary condition." The town council, which is responsible for these and many other glaring defects, resolved in September last that "the council do not concur in the observations of the medical officer of health that the housing conditions of certain areas are insanitary," and their sanitary policy, if it can be so called, is apparently one of resistance to all proposals for efficient execution of the ordinary duties of a sanitary authority under the Public Health and Housing Acts. On a vacancy which occurred over a year ago in the office of inspector of nuisances applicants were invited by an advertisement requiring them to state the salary required. Some 108 replies were received, many being from men with experience of the duties or with certificates of sanitary knowledge obtained from the Royal Sanitary Institute. The appointment, however, was given to a local builder and member of the council, stated to possess no sanitary certificate or special qualifications. While we believe that complaints against local authorities in sanitary matters are often made without much discrimination, and that frequently these authorities and their health officers are given too little credit for what they accomplish, there unfortunately seems no room for doubt in this case. It may be hoped that the incompetence described in this report is quite exceptional in its degree, and that the Local Government Board will not be content until it has been removed. We note that Dr. Mivart's investigations resulted originally from the action of the Admiralty, which is naturally concerned with the health of the inmates of the Royal Naval College which is situated in the borough. It may be expected that the Admiralty will exercise effective pressure to obtain comprehensive reforms.

THE VALUE OF COLLOID SULPHUR IN CHRONIC RHEUMATISM.

Professor A. Robin in a clinical lecture reported in the *Gazzetta degli Ospedali* of April 12th relates two cases of chronic arthritis deformans in which an extraordinary amount of benefit was obtained from the administration of colloid sulphur. Examination of many cases of chronic articular rheumatism revealed a number of discordant facts, but some characteristics common to all. They all suffered from some form of disordered digestion, especially gastric, with lactic acid fermentation. The digestion of albuminoid substances was the most defective, the elimination of lime and magnesia sensibly increased. A diminution in the elimination of phosphoric acid and an increase in the urinary chlorides were also noticed. The blood, with a reduced hæmoglobin index, contained a somewhat excessive quantity of chlorides, showing that there was a certain degree of retention. Treatment directed to these conditions produced temporary improvement, but never resulted in cure. Sulphur was at one time largely given as a remedy in chronic rheumatic conditions, and its efficacy is proved by the beneficial use of the mineral waters of Aix-les-Bains, Luchon, and Cauterets. The administration of free sulphur has, however, fallen into comparative disuse owing to its insolubility and the size of the granules which render its absorption difficult and uncertain. Maillard had the happy inspiration to resort to colloidal sulphur which is endowed with all the properties of colloidal bodies; a tablespoonful of this substance, about 15 grammes, contains 0·20 gramme of sulphur, about as much as is contained in a litre of the old preparations. It has been shown, moreover, that colloid sulphur is entirely and rapidly absorbed by the digestive tract and undergoes all the transformations by which the element is able to pass into the tissues. Its elimination by the urine is effected by one-half or two-thirds under the form of sulphates, the other half or third under the form of sulphur-containing bodies the result of its organic combinations. Colloidal sulphur may be given at the commencement in doses of two teaspoonfuls daily increasing to two tablespoonfuls; this amount should not be exceeded for fear of provoking diarrhœa.

A STUDY OF A MAN.

Mr. Morley Roberts, in "Time and Thomas Waring: A Study of a Man," has revealed with great skill the feelings of a sensitive patient suffering from excessive shock after a heroic colectomy. His hero, a genius, passionate and soured, a mixture of Pharisee and sinner, passes through a phase of agony during recovery from general anæsthetisation which assuredly has fallen to the lot of very few even in these days of major operations. So vividly is the process of return from insensibility described that we become convinced that here is the record of a personal experience. Just as the human embryo passes in utero from the cell to something fish-like, thence to something ape-like, and so to man, the consciousness of Thomas Waring passes during a very short lapse of time through all the phases of the existence of life upon this planet. As he emerges from the depths of insensibility he is in the monad stage, "a point, a point of strange fire, a live speck; something infinitely small in which was concentrated immortal, unmeasured, and infinite suffering." After what seems the process of æons the living speck becomes many specks, each advancing in agony. In other words, the cells in Waring's brain begin to interact, the enduring agony of pain extends. And at last, after what has seemed the whole life of the universe, the summation of all previous existence, the human reason emerges, and he becomes conscious of the presence of another human being in the room. This is his nurse, whose arm he grips so savagely as to bruise it. Then follows another spell of oblivion, and only very gradually Waring regains his powers of thought. But for days he has a strange metallic taste in his mouth, and conceives of the universe as a mechanism of metal. His sense of the values of things has been revolutionised. Nothing matters at all, and from having been a hard man, living a double life, he becomes the kind of philosopher who believes only in kindness. There can be no doubt that when the hero of this remarkable book first approached the operating-table there was a great weight upon his mind, which was besides morbidly awake—he was a famous journalist—to every kind of impression and to the thought of possible death. Consequently, after an operation lasting two hours his poor body suffers a fierce shock, which is followed by strange ethical results. Mr. Morley Roberts has presented an exceptional case in a skilful manner. He has, moreover, dedicated his book to his many medical friends, and though he represents his professional characters as talking together in a strangely unprofessional manner, his dedicatees will be more inclined to chuckle than to grumble at this. In the famous preface to "The Doctor's Dilemma" the medical profession is manhandled, but in the novel before us it is criticised by a sympathetic admirer. The severest judges of the book will probably be found among that army of martyrs who have been themselves operated upon. The average man who has undergone appendicectomy or an operation for piles has probably during anæsthesia and recovery therefrom had experiences quite different from those recorded for Thomas Waring. In such matters individual experiences vary through an enormous range.

HYDATID CYST OF THE BRAIN.

Hydatid cyst of the brain is sufficiently uncommon to render all cases worth notice. In the *Australian Medical Journal* of Jan. 17th Dr. T. F. Ryan has reported two cases which present many features of interest. A girl, aged 6½ years, was seen in June, 1911, with a history of gradual loss of power in the right hand and arm during the previous three weeks. Examination showed some weakness of the right hand and arm. There was no muscular wasting or loss of sensibility. Observation over several days revealed the fact that at times the right radial artery ceased to beat at the wrist for periods of several hours. The brachial artery could always be felt to pulsate normally. A skiagram of the right shoulder showed nothing abnormal. The tendon reflexes in the right arm were normal and the plantar reflexes were flexor. There was some tendency to incoördination of the movements of the arm. The fundi were normal, but there was a little indefinite nystagmus. During 1912 the patient was seen on a few occasions when it was evident that the whole of the right side was becoming involved. There was some contraction of the flexors of the elbow, wrist, and fingers, and weakness of the leg, mainly in the extensors, with paralytic equino-varus. Paresis of the right side of the face was present, and the tongue was deviated to the right. On the right side the tendon reflexes were exaggerated and the plantar response was extensor. In December weakness became manifest in the left arm and leg, and speech became difficult and hesitating. Examination showed right hemiplegia affecting face, arm, and leg with flexor contracture. The left arm was weak and ataxic. All the tendon reflexes were extremely active. Except for a small patch of anæsthesia over the right shin sensibility was normal. There was double optic neuritis, slight in the right eye, well marked in the left. Percussion of the head gave "a peculiar high tympanitic note" in the left fronto-parietal region. A lateral skiagram of the head showed thinning of the skull in the fronto-parietal region; an antero-posterior skiagram, thinning in the left fronto-parietal region and the outer circumference of a cyst. On Jan. 31st, 1913, an osteoplastic flap was turned down over the left Rolandic area. The skull here was very thin, in some places less than 2 mm. in thickness. The dura mater showed no tendency to bulge and no pulsation, and the flap was replaced. On Feb. 5th the second stage was performed. On removing the bone flap and incising the dura mater a large hydatid cyst presented and was removed. It occupied a large part of the left cerebral hemisphere, its greatest convexity being in the Rolandic area. The bone was not replaced, but the soft tissues were sutured and a small rubber drain was inserted from which serous fluid flowed for a few days. On April 23rd the optic neuritis disappeared and speech became almost normal. There was still some contraction of the flexors of the right arm and some weakness of the right leg with foot-drop. In January, 1914, she could walk well and use her right arm very well. It is noteworthy that at no time was there any headache or vomiting. In the second case the patient, a farmer aged 43 years, had not such a fortunate experience. He was in perfect health until October, 1910, when he fell to the ground whilst ploughing and was carried home unconscious. After 15 minutes he vomited and recovered consciousness. Next morning he resumed work and remained well for six weeks. He then complained of violent headache, which continued for six weeks, until Dr. Ryan saw him for the first time. His mental and physical condition was good, and there was no paralysis or abnormal reflex. There was double optic neuritis. That night he slept well for five hours, and then called out to the nurse who found him unconscious and breathing stertorously. He died in about an hour. The necropsy showed a hydatid cyst of the size of an orange near the left fissure of Rolando.

IS THE REFLEX THE FUNCTIONAL NERVE-UNIT?

IT is not an infrequent phenomenon that in the advance of some branch of science there is evolved an outstanding tenet which later work appears to support, and upon which, as a basis, real advance is made, but which itself is finally uprooted by the very observations which it has stimulated. It appears as if a fate of this kind may befall the long-accepted view that the reflex arc constitutes the basal functional nerve-unit. The reflex, as we know it in its simplest form, is made up of a centripetal or afferent process, whose activity is reflected through the grey matter of the cord into an efferent, effector, or centrifugal mechanism. A reflex which has received very full attention is that of the step, the normal act of progression. In such an act the afferent stimulus was held to be received from the peripheral tegumentary receptors, added to which, as Sherrington showed, are also the stimuli from muscles and joints, the propioceptive receptors. Such stimuli were held to evoke the necessary efferent movements, actions characterised by their rhythmic alternation of opposing forces, and the underlying basis of which was the graded antagonistic opposition of muscle groups, flexion being aided by simultaneous inhibition of extension, and *vice versâ*. Rhythmic progression is conditioned by an equal balance of two antagonistic central activities. Are these activities of fundamentally peripheral origin? If we accept the true reflex mechanism as being responsible for them we are bound to admit that they are. Against this view, however, Dr. Graham Brown, in the current issue of the *Journal of Physiology* (1914, Vol. XLVIII., p. 18) reviews, on the basis of much experimental work of his own and others, the evidence which opposes this idea, and himself advances suggestions which, in brief, allocate to the efferent nerve-units and not the reflex arc the fundamental functional nerve-unit. He has shown, firstly, that the act of progression can occur after all afferent channels, exteroceptive or propioceptive, have been abolished by deep narcosis and section of nerves. This demonstrates independence from the afferent system. Now it has been shown that rhythmic phenomena are conditioned during the balance of equal and antagonistic opposite activities in the antagonistic "half centres"—i.e., the two efferent neurons to antagonistic muscles. It is conceivable, therefore, that, even in the absence of peripheral stimuli, the factors of fatigue and "rebound" in such centres may explain the rhythm. But Dr. Brown's experiments have shown that with the degree of narcosis he employed both these factors were eliminated. He suggests that the activation of the half centres may be fundamentally conditioned by a stimulus equivalent to the blood stimulus in respiration. Such stimuli may be slight in degree; but it is known that stimulus is most effective when there is a close approximation to an equal and opposite activation of the half centres, so that slight changes would be sufficient. So far, the reasoning is certainly in favour of the truth of the writer's contention. There is next to be asked, however, Of what value are the peripheral stimuli? Do they count for nothing? It is suggested, and here certain facts of evolution enter into the argument, that the spinal reflexes which excite progression are in the nature of distortions of the "beat" of the fundamental rhythm. The fundamental rhythm, being, as the experiments showed, the last to be abolished, is essentially of more primitive and fundamental origin. Originally it was possibly conditioned by circumstances closely allied to the more elemental blood stimuli with its asphyxial changes and in the mechanisms of which afferent organised channels played no part. It was the later organisation which added higher complexity. The reflex was grafted on, as it were, to the fundamental rhythm. Such an addition is represented by the normal reflexes of progression; and this now dominates, by distortion of the original beat, the original rhythm. But it remains a superimposition. It is not, in essence, the fundamental nervous mechanism. We see in this paper a carefully reasoned case against the currently accepted view, and one which must meet with a measure of acceptance until further evidence is forthcoming.

THE RELATION BETWEEN DEFECTIVE AND PROLIFIC STOCKS.

THE paper by Mr. M. Greenwood, jun., and Mr. G. Udny Yule on the Determination of Size of Family and of the Distribution of Characters in Order of Birth from Samples taken through Members of the Sibships[1] is one of considerable importance in that it impugns on statistical grounds statements made on high statistical authority, which if true would give serious cause for alarm. These statements are, first, that defective stocks are more prolific than the normal; and, secondly, that the earlier-born members of a family are more liable to exhibit defects than the later born. The significance of the latter view rests on the fact that the decline in the average size of the family, which has indubitably taken place in recent years, means that the proportion of first- and second-born has increased. Both circumstances would thus lead to an increasing prevalence of defect. Mr. Greenwood and Mr. Yule express their criticisms in a mathematical form, but the principles on which their reasoning is based are quite easily intelligible to persons without mathematical training and appear obvious when pointed out. Bulletins No. 10A and 10B of the Eugenics Record Office (Cold Spring Harbour, Long Island, New York) contain the report of the "Committee to Study and to Report on the Best Practical Means of Cutting Off the Defective Germ Plasm in the American Population." No. 10A describes the scope of the committee's work and No. 10B the "Legal, Legislative, and Adminstrative Aspects of Sterilisation." The latter contains a valuable summary of the sterilisation laws which have been passed in 12 States of the American Union, and of the Bills introduced in other State legislatures which did not become law, but were either thrown out or vetoed by the governor or revoked by referendum. The result of all this legislative activity has been very meagre. In only three States have any sterilisation operations been performed under the statutes—namely, about 300 in Indiana, 268 in California, and 7 in Connecticut. At the present time no operations of this kind are being performed as the constitutional nature of the laws is in question. But although they are dormant it would be premature to conclude that they are dead.

"LOCALISED" TUBERCULOSIS IN THE PIG.

A REPORT made to the Local Government Board by Dr. A. Eastwood and Dr. F. Griffith,[1] which has been issued recently, gives the results of a valuable series of observations on the distribution of visible tuberculous lesions and of tubercle bacilli in a considerable series of pigs selected at the slaughter-house as examples of minor degrees of pig tuberculosis. The term "localised" tuberculosis is often loosely used in meat inspection, but in the sense in which it is used in this report it signifies disease which as a result of naked-eye examination is apparently confined to the lymphatic glands in relation to the alimentary tract. It is clear that among the ordinary pigs which come to the slaughter-house tuberculosis which is actually localised in this way is much less common than tuberculosis which is more or less widely disseminated. Thus at the Brighton abattoir, from which a large part of the material was obtained, 24,144 pigs were examined during the period of selection, of which 209 were reported by the meat inspector to be affected by general tuberculosis, 393 had slightly disseminated tuberculosis, while localised tuberculosis was present in only 59. The pig, as the work of the Royal Commission on human and animal tuberculosis showed, is susceptible to infection with various bacilli of mammalian type (including bovine and human) and with avian bacilli. By far the most common source of its natural infection is the bovine, derived from tuberculous milk or from the tuberculous fæcal discharges of cattle; but avian infection may also arise from ingestion of the excreta of fowls affected by the disease, while in one or two of the series here reported on the bacilli were found to be of the eugonic type, of low virulence for rabbits, indicating a human source of infection. Avian infection in the pig appears to have much smaller tendency to dissemination—when judged by the presence of naked-eye tuberculous lesions—than bovine infection. As a rule, though not invariably, when infection was due to avian bacilli the affected glands were either not enlarged or only slightly so; and they contained gritty or calcareous nodules which were easily shelled out of the surrounding tissue, leaving behind smooth fibrous-walled cavities. With bovine infection, on the other hand, a greater degree of local gland affection was apparent, and when closer examination was made in the laboratory of lungs, liver, spleen, and certain other tissues of the pigs which had been classified in the slaughter-house as examples of "localised" tuberculosis, naked-eye evidence of dissemination was frequently found. Of the 59 pigs above referred to, for example, the disease was ascertained by this special examination to be strictly localised only in 24. In regard to the presence of tubercle bacilli in apparently normal organs and tissues, it was noteworthy—and reassuring in view of the comparative harmlessness of the avian bacillus to man—that the bacilli were readily found in tissues presenting no naked-eye lesions when avian infection was in question, but very seldom in the case of bovine infection. The interesting observations in this report will have special interest for those medical officers who are consulted in connexion with meat inspection. The Royal Commission of 1896 went so far as to recommend that the whole carcass of the pig should be regarded as unfit for food if tuberculosis was present in any degree, and their finding receives some support as a result of these investigations. In practice, however, the recommendation has often been considered too drastic to be generally acted upon, and various modified standards of condemnation have been adopted instead. It may be concluded from the report that where partial condemnation is practised it is important that the examination of the carcass and its organs at the slaughter-house should be thorough, so that the extent to which the animal is affected can be accurately gauged. It should be added that the large amount of pathological work which Dr. Eastwood and Dr. Griffith have undertaken for this report is very fully reported and tabulated. In one or two instances the examination of the tuberculous lesions of the pig demonstrated the coexistence of mammalian and avian bacilli, or of different kinds of mammalian bacilli, in the same animal.

THE ELECTRICAL TREATMENT OF MILK.

WE have received a copy of the report of the city bacteriologist of Liverpool (Professor J. M. Beattie), which presents the details of the experimental inquiry and apparatus involved in the electrical treatment of milk. The results show the complete destruction of disease-producing bacteria, while the chemical constitution of the milk remains unimpaired and the taste is not altered, so that the milk from this point of view may be described according to this report as "raw milk." The conclusions reached are so momentous that we propose to deal with the report in greater detail in a future issue.

THE HISTORICAL MEDICAL MUSEUM.

THE Historical Medical Museum, which was founded by Mr. Henry S. Wellcome in connexion with the Seventeenth International Congress of Medicine, will be reopened on May 28th as a permanent institution in London. It will be known in future as the "Wellcome Historical Medical Museum" and will be open daily from 10 A.M. to 6 P.M., closing at 1 P.M. on Saturday; entrance 54A, Wigmore-street, Cavendish-square, W. Members of the medical and kindred professions will be admitted on presenting their visiting cards. Since closing last October the collections in the museum have been considerably augmented and entirely rearranged. Many objects of importance and interest have been added, which it is hoped will increase the usefulness of the museum to those interested in the history of medicine.

THE INTERNATIONAL SURGICAL ASSOCIATION.

(FROM OUR OWN CORRESPONDENT.)

THE Fourth Congress of the International Surgical Association was held at the Hotel Astor, New York, from April 13th to April 16th inclusive.

The Association meets triennially, and hitherto the meetings have taken place in Brussels; but as Professor A. Depage, of Brussels, President of the Fourth Congress, explained in his opening address, the Association was delighted to accept an invitation to hold a meeting in America, having a high esteem for their American colleagues and for American ideas of peace and civilisation throughout the whole world.

About 100 foreign members attended the meeting, many of them accompanied by their wives, and an almost equal number of members from the United States were present. Moreover, as the annual meeting of the American Surgical Association, which also was held in the Hotel Astor, only terminated its sessions on April 11th, there was a large number of surgeons both from the United States and Canada present at most of the society's meetings. New York and Chicago were well represented; the same may be said of Montreal and Toronto, the visitors from these cities, with Dr. Hamilton Russell, of Melbourne, standing for British surgery in the unavoidable absence of members of the society from the British Isles.

The Opening Meeting.

The opening general meeting, at which many ladies were present, took place at 11.30 A.M., in the grand ballroom of the Hotel Astor. The attendance was large, and of the foreign members Germans were in the majority. In the unavoidable absence of the PRESIDENT of the United States, owing to stress of national affairs, Surgeon-General WILLIAM C. GORGAS presided. and welcomed the Association.

Dr. WILLIAM J. MAYO, of Rochester, Minnesota, president of the American Surgical Association, welcomed the foreign members in the name of that organisation. He was particularly gratified, he said, that the first meeting of the society held outside Brussels should be held in New York. The American medical profession owed a deep debt of gratitude to Europe, for American medicine and surgery started from the shoulders of Europe. He had been asked frequently, whether he thought that Americans had developed their own type of surgery, and he had always answered No. For nearly a century they had depended upon Europe and the British Isles; although there had been and were good surgeons in America, the origin of their knowledge and skill was Europe. He concluded by hoping that the members would go to all the big cities of the United States, for he felt certain that surgeons throughout the country would take the greatest pleasure in showing them all there was to be seen.

In the absence of Professor M. CHARLES WILLEMS, of Ghent, the President of the International Surgical Association, Dr. J. P. HOGUET, of New York, Secretary of the Congress, read his address in French and English. This consisted of a welcome to the members of the Association, a hearty expression of thanks to their American hosts, and an affirmation of the important place in surgery now taken by the Association. He closed by referring to the loss which the society had experienced in the death of the late lamented Dr. Lucas-Championnière, who presided over the Congress with so much dignity and tact in 1911.

Dr. L. L. MACARTHUR, of Chicago, chairman of the American Committee, who spoke next, made feeling references to the loss sustained by surgery in the death of Dr. Roswell Park, the great Buffalo surgeon having had much to do with the early organisation of the society. It was sad that having worked so hard for the success of the movement, he should not have lived to witness the first meeting in his native country.

Professor A. DEPAGE then delivered his presidential address. After expressing his pleasure in accepting the invitation of American surgeons, he paid a special tribute to the contributions made by America to military surgery. He pointed out how the time had passed when the art of war was but a manifestation of exalted personal courage; it had now called science to its aid in every department, including those of military surgery and sanitation. American medical writers, such as Borden and O'Reilly, had rightly laid stress on the responsibility entailed by the practice of military surgery and on the need for thorough medical organisation of armies. Precautions which would have sufficed in former times were inadequate at the present day. Professor Depage insisted on the necessity for development of the international understanding in the matter of ambulance services. Red Cross organisations had already done much, but the responsibility of the surgeon increased with the dangers of the present time. The Balkan war had emphasised the lesson taught by the war in Manchuria—viz., that the fate of the wounded depended more than anything upon the aid given at the front of the battle, since while an engagement lasted the exposed ground was inaccessible to the ambulance men. Every combatant should carry with him, side by side with his cartridges, the articles necessary for a first dressing. Various countries had already adopted this solution of the difficulty, but a uniform first-aid outfit was desirable, and, above all things, the sanitary education of the soldier must be improved; he must be made to realise the dangers of infection by earth, dust, and water, and the elementary principles of asepsis. But although immediate aid was most efficacious on the battlefield, this help should be limited to precautionary measures. Serious operations, such as amputations and extraction of bullets, should be reserved for hospitals of the second line, provided with experienced surgeons and with civil consultant surgeons attached on regular duty. During recent wars surgeons had been filled with astonishment at the comparative harmlessness of the modern gun; but the so-called "efficacy of the shrapnel" was too horrible, and the Imperial Surgical Society at Constantinople in December, 1912, expressed the fervent wish that the use of shrapnel might be abolished on the same grounds as the explosive bullet. The President concluded his address with a moving plea for universal peace.

On the afternoon of April 13th papers were read and discussions took place on the

Technique of Amputations.

The first paper was read by Dr. WITZEL, of Düsseldorf, and dealt with amputation of the arm and forearm. Dr. Witzel gave as his conclusion that the indications for an amputation could only be pronounced upon by those in touch with all the modern resources for the preservation of wounded, diseased, and deformed limbs. While the aseptic treatment of open wounds, contusions, and fractures allowed the postponement of amputation in time of war as well as in ordinary practice, the processes of suture, resection, anastomosis, and transplantation of the blood-vessels led to the preservation of parts of limbs wounded or affected by arteriosclerosis. Bier's method of prophylactic hyperæmia, together with small carefully made incisions in the suppurating parts, would preserve limbs when septicæmia and pyæmia would have otherwise demanded amputation. Modern operative orthopædics by means of osteotomy and musculotendinous transplantations could restore their powers to useless limbs. Dr. Witzel reminded his hearers next that in cases of simple tumours and in myeloid sarcoma excision followed by transplantation was more than ever justified. In malignant tumours radiotherapy and chemotherapy were giving great promise.

Amputation of itself, he said, can never endanger life, and should procure for the patient a useful and painless stump, the following being his generalisations.

(*a*) The danger of the actual operation is decreased by an increase of the resisting powers of the subject, whether it is a case of emergency or not; there should be complete arrest of hæmorrhage in accidents; the heart action must be strengthened by drugs, saline infusions, inhalation of oxygen, application of heat, and respiratory exercises. Esmarch's tourniquet and preservation of warmth during the operation all play their part. The choice of the anæsthetic is also an important factor. General anæsthesia is preferable on account of the psychic effect resulting from amputation, Hackenbruch's process is suitable for minor operations, Braun's endoneural anæsthesia for bigger removals, always with addition of narcotics and with strict attention to discipline in the working of the operating theatre; Bier's rachi-anæsthesia will rarely be indicated.

(*b*) After the operation life will be preserved mainly by simple and thorough asepsis, the carrying out of which depends as much on the choice of the site of amputation as in the technique itself. The possibility of operating in a clean manner permits the use of more complicated methods. The section of tissues should be clean; in order not to injure their vitality it is necessary to work with "gentleness, heat, and moisture." For this end the use of antiseptics must be avoided, and there must be a strict arrest of hæmorrhage. Cardiac tonics and respiratory exercise prevent thrombo-embolism.

(*c*) To obtain a painless and serviceable stump clean section is necessary well above the nerve stumps; the production of neuritis by fixation of the nerve roots on the surface of the divided bones must be avoided. Protective occlusion of the medullary canal by the processes of Bier, Wilms, Ritter, or Bunge also prevents this accident. Methodical movement of the soft tissues by massage and early utilisation of the stump in temporary artificial limbs serve the same purpose. For a good utilisation of the stump as a lever for future apparatus regard must be taken of the unequal retraction of the muscles and tendons, while the suture of neighbouring muscles in opposing groups between themselves helps to maintain functional equilibrium.

Dr. P. VON KUZMIK, of Budapest, contributed a paper on Amputation of the Hand. He considered that before proceeding to amputate the hand or even a finger the surgeon is in duty bound to try every physical method of treatment—heliotherapy, Roentgen rays, Bier's hyperæmia, thermotherapy, and immobilisation. For amputation of hand or fingers, all the modern methods have given good results and all operators ought to be as conservative as possible.

Dr. J. F. BINNIE, of Kansas City, read a paper on Amputations of the Leg. No particular improvement has been made in the methods of amputation below the ankle-joint. Amputations through the leg (below the knee) seem all to be equally safe no matter at what level they are performed. If a good weight-bearing stump is secured, then the more of the leg that is retained below the knee the more useful will it be to the patient. The improvements in amputations of the leg are all in the direction of better weight-bearing stumps and the designs of artificial limbs must in the future adapt themselves to these improvements. Hirsch and Bunge's aperiosteal treatment of the bony stump in any amputation and osteoplastic amputations under particularly favourable circumstances are, he said, "very valuable means towards obtaining ideal weight-bearing stumps. Free transplantation of a fragment of bone to the end of the divided tibia may replace the more difficult and complicated osteoplastic methods of Bier and others."

Dr. M. DURAND, of Lyons, read a paper on Amputations of the Leg and Foot. He summed up his conclusions as follows:—

I. *Amputation of toes.*—One of the three middle toes may be amputated (*a*) by disarticulation of the second phalanx, (*b*) by metatarso-phalangeal disarticulation, and (*c*) by amputation in continuity of the first phalanx. These operations do not alter the functions of the foot. The conditions apply to the little toe, and no other operation is recommended. Total disarticulation of the great toe, especially if carried out by the subperiosteal method, gives an excellent result. Simultaneous disarticulation of the five toes makes but slight difference to the walk.

II. *Amputation of the metatarsal bones.*—Amputation of one of the four last metatarsal bones, in continuity or by disarticulation, presents but small difficulty. The disarticulation of the first metatarsus is a little more serious from the functional point of view, but has not the disadvantages ascribed to it, the subperiosteal method being particularly favourable. More than two metatarsal bones must not be amputated, keeping the others. Transmetatarsal and tarso-metatarsal amputations give generally excellent functional results.

III. *Amputations and disarticulations of the anterior tarsus* which do not suppress it entirely must be recommended; their results are very similar to those of Lisfranc's disarticulation. But Chopart's disarticulation is an unreliable operation; it should be reserved for exceptional conditions.

IV. *Amputations of the posterior tarsus.*—Ricard's operation and sub-astragaloid disarticulation are both excellent and have practically the same value. The osteoplastic amputations of the posterior tarsus (those associated with the names of Sédillot, Pirogoff, Pasquier-Lefort) are useful, and the tibio-tarsal disarticulation (Syme or Jules Roux), carried out according to Ollier's subperiosteal method, gives a supple and enduring stump; it leaves such good functional results that it may be considered equal to the greater part of the more conservative operations of the posterior tarsus.

V. *Supra-malleolar amputations.*—Amputations of the lower third of the leg, employing in the stump solid skin tissues obtained from the heel, sometimes permit the direct resting of the stump on any necessary artificial limb; the length of the leg lever and the power of the muscles which they preserve give a usefulness here very similar to that which follows tibio-tarsal disarticulations.

VI., VII., and VIII. *Amputations of the middle third of the leg* require modification, and *amputations of the leg above the middle part* should be performed only when the extent of the injuries does not permit a lesser sacrifice. Larrey's intracondylar amputation appears preferable to the disarticulation of the knee.

IX. Amputations of the leg and foot owe their gravity solely to the affection which necessitates their performance, and to the general condition of the patient. The progress of surgical technique and of asepsis has done away with the primitive formation of stumps, enabling a more correct adaptation of the stumps to the suitable apparatus. Manufacture of this has considerably improved, and the need for amputations of the middle and lower third of the leg has to a large extent disappeared.

Dr. E. RANZI, of Vienna, read a paper on Amputations below the Knee, in which he supported Bunge's methods, while pointing out that in every amputation it is of importance that the patient should take walking exercise and have massage, as well as put his weight on the artificial limb as soon as possible.

Among those who took part in the discussion were Dr. DEPAGE, of Brussels; Dr. STEINTHAL, of Stuttgart; Dr. MORESTIN, of Paris; Dr. FRANKE, of Braunschweig; Dr. LORTHIOIR, of Brussels; Dr. ZAHRADMKY, of Heneky-Brod; Dr. LAMBOTTE, of Antwerp; and Dr. RITTER, of Posen.

(*To be continued.*)

THE
PREVALENCE OF PNEUMONIA AMONG THE NATIVE LABOURERS ON THE RAND.

THE fact that the mortality among the native labourers on the Rand was excessive has long been notorious, and it has formed the subject of official inquiry from time to time. The last annual report of Dr. Charles Porter, medical officer of health for the municipality of Johannesburg, shows that the chief cause of this high mortality is pneumonia.

In 1911 a special report was prepared by Mr. G. D. Maynard, at the request of Dr. Porter, on the incidence of this disease in the workers in the mines, but it was found that no comparison of one mine with another could properly be made without due consideration being given in each case to such factors as territorial origin of the native workers, diet, nature of housing, depth of the mine, and general sanitary conditions. Sir Almroth E. Wright, who visited Johannesburg for the purpose of ascertaining if the prophylactic inoculation of a pneumococcal vaccine might serve to protect the African natives on the Rand from the ravages of pneumonia, presented a report which was published in THE LANCET.[1] More recently the mine owners in 1913 invited Surgeon-General Gorgas, of the United States Army Medical Corps, whose successful work in lowering the mortality of certain diseases in Cuba and in the Panama Canal Zone is so well known, to make an investigation on the spot and advise as to the best means of preventing the present heavy loss of human life on the Rand. His report, we understand, has not yet been published.

Report on Results of Inquiry.

Meanwhile a very valuable further contribution to the literature of the subject has been recently supplied by Mr. Maynard, now statistician and clinician to the South African Institute for Medical Research, in the form of a memoir issued by that institute.[2] This investigator has the advantage of possessing a wide local knowledge of the circumstances of labour on the Rand, since he was formerly assistant medical officer to the Witwatersrand Native Labour Association. He brings also to his aid in attempting to solve some of the problems the application of the highly technical mathematical methods now employed by modern statisticians. He defines the pneumonia which is met with on the Rand as meaning the disease clinically known as lobar pneumonia when bacteriologically associated with the pneumococcus of Fraenkel. The majority of the "tropical natives" brought to labour in the mines are obtained from the Portuguese districts of Quilimane, Mozambique, Tete, and Portuguese Nyasaland; they are recruited at their kraals and then marched in gangs from rest-camp to rest-camp down to the coast, where at one or other of the ports they embark for Lorenzo Marques, the voyage lasting for several days. After landing they entrain there for the Transvaal, stopping for a few days for medical examination at the low veld station of the company at Ressano Garcia. If found healthy they are passed on to the association's compound at Johannesburg, and remain there under close medical supervision for a further period of at least three weeks. At the end of this time they are again medically examined, and if regarded as fit for work they are allotted to one or other of the mines. It is a fact worth noting that it is during this period of their stay at the Native Labour Association's compound, and before they have begun to work in the mines, that many of the cases of pneumonia are reported, and there is no doubt that the greatest incidence of the disease occurs immediately on the arrival of the natives on the Rand, and that it decreases as the length of their residence increases.

Johannesburg is situated at an altitude of 6000 feet, and therefore climatic conditions are likely to be different there from those to which some at least of the natives have been hitherto accustomed. It appears that pneumonia is most prevalent on the Rand during the cold season, and that second and even third or more attacks are by no means uncommon. A fatal termination is most frequently noted about the fourth day of the illness. Mr. Maynard comes to the conclusion that both the pneumonia attack-rate and the death-rate among "tropical natives" are influenced by the country of origin from which the labourer has come, and the highest attack-rates are found in those persons having the poorest physique. Pneumococcal meningitis as a complication of pneumonia seems to be more common among the "tropical natives" than among Europeans. There is, he thinks, no evidence that pneumonia spreads from case to case. The prophylactic inoculation of a pneumococcal vaccine when employed immediately on the arrival of the natives on the Rand appears to reduce the incidence of the disease for a limited period, but the experimental treatment of cases with a pneumococcal vaccine did not favourably affect the fatality of the disease.

Bacteriological Questions.

Mr. Maynard, in concluding his report, admits that his investigation has not succeeded in throwing much new light on the problem of the causes which lead to the attack of newly arrived native labourers by pneumonia; further inquiries are therefore necessary before any satisfactory pronouncement can be made. He has, however, recently begun the examination of the nasal and throat secretions of a small number of "East Coast" natives after their arrival on the Rand, in order to determine whether the pneumococcus is present at that time; and although the series of examinations is not yet completed, it appears that it is not uncommon to find the organism in the natives' nasopharynx within a few hours of their arrival in the compound at Johannesburg. It will consequently be advisable to find out if the pneumococcus exists in the nasal passages of these natives when they are at home in their kraals, and, if not, at what point of their journey to the Rand they become infected.

[1] THE LANCET, Dec. 14th (p. 1633) and 21st (p. 1701), 1912; Jan. 3rd (p. 1) and 10th (p. 87), 1914.

[2] An Inquiry into the Etiology, Manifestations, and Prevention of Pneumonia amongst the Natives on the Rand, Recruited from Tropical Areas, by G. D. Maynard, F.R.C.S. Memoir No. 1, published by the South African Institute for Medical Research, Johannesburg, November, 1913, pp. 123, with maps and charts. Price 5s.

Mr. Maynard regards it as being of practical importance to discover whether change of climate is accompanied by the appearance of the pneumococcus in a previously uninfected nasopharynx, or whether there is no increase in the rate of such infections owing to change of locality. It is possible that some other conditions, such as lowered resistance brought about by change of climate, may be factors in the morbid process that occurs in the natives. It is difficult to obtain trustworthy information from native sources, but it appears to be likely that pneumonia occurs among the people at home in their villages. A suggestion is made that there may be several strains or varieties of the pneumococcus possessing different properties and qualities of virulence, and that perhaps one strain affords no immunity to the attacks of another strain. Arrangements, we learn, are being made at the South African Institute to carry out further inquiries on the lines above indicated, including the examination of the natives under ordinary conditions at their own kraals, as well as at the various resting camps and compounds situated on the routes usually followed to reach the Rand.

Further Investigations.

It is worth mentioning in conclusion that when, in 1912, the Union Government of South Africa appointed a Commission, of which Dr. Porter is a member, to investigate the subject of tuberculosis, an instruction was given that they should also "inquire into and take evidence for the purpose of ascertaining the extent and causes of the mortality of natives employed in the Witwatersrand mines, and their susceptibility to pneumonia, with special reference to those coming from tropical areas, and to make recommendations thereon." This Commission has not yet presented its report, but we presume it will not long be delayed. It is hoped that with this and Surgeon-General Gorgas's report, supplemented by the further investigations of the South African Institute already referred to, most of the doubts and difficulties concerning this disease in the Rand district will be cleared away. Surgeon-General Gorgas's report is fully dealt with this week by our Special Correspondent on the spot.

REPORT OF THE TROPICAL DISEASES RESEARCH FUND.[1]

SINCE the Tropical Diseases Research Fund was established about ten years ago the advisory committee has effected a large amount of valuable work, but it is somewhat humiliating to a colonising nation like ours to find that the British Government does not give anything like adequate support to the scientific researches which have done so much already to reduce the excessive sickness and mortality rates recorded in many of our colonies and protectorates. The present income of the fund is unable to meet in a proper manner the pressing requirements of tropical research, the total receipts being only £3445, of which the British Government contributes £1000 and India £500, while the Dominion and Colonial Governments give £1945.

The Expenditure of the Fund.

The expenditure for 1913 amounted to £3600—that is, £155 more than the income—the excess having to be met, as in some previous years, by drawing upon a balance accumulated in the past. It is obvious that something should be done to place the finances on a sounder basis. The committee strongly urge the extreme desirability of having the income increased in view of the many directions in which important researches might be instituted for the benefit of our tropical colonies and dependencies if only sufficient means were permanently available. In allocating the grants, and looking at the unsatisfactory position of the finances, it was carefully considered whether a reduction could be made in the amounts voted to the Schools of Tropical Medicine in London and Liverpool; but on certain representations being made it was decided to give £1200 to each of them, £750 to the University of London, and £450 to the University of Cambridge. The grant to the London School was expended in paying the salaries and maintaining the laboratories of the teachers and investigators of helminthology, protozoology, and entomology. The Liverpool School employed their grant to defray the cost of special researches in their laboratories on trypanosomiasis, general parasitology, helminthology, and entomology, as well as in carrying out some investigations on malaria. The sum given to the University of London was used as before in paying the salary of the professor of protozoology, and the grant to the University of Cambridge was employed partly to support a research studentship in medical entomology, partly in helping to pay the salary of an assistant in the Quick Laboratory and also that of a helminthologist, and partly in assisting to defray the general expenses of that laboratory. It is worth noting that the sum given to the University of Cambridge in 1913 was larger by £100 than in the previous year; in the opinion of the committee this increase was amply justified by the importance and extent of the research work carried on in the Quick Laboratory by Professor Nuttall and his assistants.

The Work of the Advisory Committee.

The committee was consulted during the year on a variety of matters by the Secretary of State, among other things being the important question of the measures to be taken to safeguard India and our Eastern colonies against the danger of the introduction of yellow fever after the opening of the Panama Ship Canal. To their report the committee have appended a number of returns received from certain colonies and protectorates in accordance with a request contained in the circular despatch dated Dec. 20th, 1910; these give statistical and other information respecting mosquito-borne diseases, including malaria, blackwater fever, yellow fever, filariasis, and dengue, and contain also a brief account of the antimalarial measures adopted in each colony or protectorate. The committee, it appears, attach much importance to the regular receipt and careful preparation of these returns, and they call special attention to the excellence of those received from South Nigeria and the Straits Settlements. In the appendices affixed to the committee's report are reports of the London and Liverpool Schools of Tropical Medicine, the report of the Professor of Protozoology in the University of London, and the report on the work carried on in the Quick Laboratory at Cambridge. Appended also are a number of reports on laboratory and field work from some colonies. So far as considerations of space permit, we make a short reference to most of these reports.

The Report of the Professor of Protozoology in the University of London.

Professor Minchin among other work continued his investigations, in conjunction with Dr. J. D. Thomson, on trypanosoma lewisi. He has had to modify his former opinion as to the way in which the rat received its infection, having formerly held that the trypanosomes were regurgitated from the infected flea's stomach through the proboscis, and then entered the rat by inoculation of the skin. His experiments, however, have failed to support this view, and he now admits that the opinion expressed by Nöller and by Wenyon is likely to be the correct one—namely, that the trypanosomes pass out of the flea in the fæces and the rat becomes infected by licking the fæces off its skin. Professor Minchin's work, we regret to learn, was somewhat hindered for a time by the state of his health. Various researches were conducted in his laboratories by other investigators under his supervision. His assistant, Dr. H. M. Woodcock, made two special researches—the first on a remarkable parasite of the goat and other ruminants and certain flagellates which develop in goat dung, the second being on the possible transmissive agent or agents of the blood parasites of common British birds.

The Work Done at the Quick Laboratory, Cambridge.

No fewer than 23 scientific papers were published during the year by workers in the Quick Laboratory. These papers dealt with pathogenic protozoa and the diseases caused by them, the structure and biology of ticks, and observations on the biology of insects. Professor Nuttall states that probably the most interesting results obtained in 1913 were those relating to the conditions influencing the transmission of East Coast fever, the reproduction of Canadian "tick paralysis" in a dog in Cambridge by means of a single imported tick, and the observations of parthenogenesis and variability in ticks under experimental conditions.

---

[1] Report of the Advisory Committee of the Tropical Diseases Research Fund for the Year 1913. Presented to both *Houses of Parliament* by command of His Majesty. London: His Majesty's Stationery Office. 1914. *Pp.* 239. *Price* 2*s.* 4*d.*

Research Work at the London School of Tropical Medicine.

For six months Dr. R. T. Leiper, the helminthologist, was in West Africa investigating the carrier of filaria loa, the causal agent of "Calabar swelling." On his return he was engaged with Surgeon Atkinson, R.N., in examining the collection of entozoa, made by the Scott Antarctic Expedition, containing trematoda, cestoda, acanthocephala, and nematoda. Dr. C. M. Wenyon, the protozoologist, conducted researches on leishmaniasis from South American skin lesions, on trypanosoma lewisi, and on T. rhodesiense, the two latter in conjunction with Dr. H. M. Hänschell. Later in the year Dr. Wenyon went to Malta to carry out observations on Oriental sore and sandflies, and also to study human and canine kala-azar. The entomologist, Lieutenant-Colonel A. Alcock, furnishes routine reports, and, among other work, observations and experiments were carried out to elucidate or confirm the life-history of the human flea, the cat flea, the blue flesh-fly, and the bed-bug.

Research Work at the Liverpool School of Tropical Medicine.

Professor J. W. W. Stephens and Dr. H. B. Fantham made a series of further measurements of trypanosoma rhodesiense and T. gambiense, and Professor Stephens with Dr. B. Blacklock studied the morphology of two strains of T. brucei, one from Uganda and the other from Zululand. Some observations on external myiasis in a monkey were carried out by Dr. Blacklock and Mr. H. F. Carter. Professor Warrington Yorke and Dr. Wakelin Barrett made some experiments in hæmoglobinæmia and on the relationship of hæmoglobin to bile pigments. An examination of the efficacy of stibium trioxide (trixidin) as a remedy for trypanosomiasis was carried out by Professor Yorke and Dr. Blacklock, and the same investigators also studied the trypanosomes causing dourine (mal de coït), and dealt with the classification and identification of the more important mammalian trypanosomes. Dr. H. B. Fantham investigated the spirochætes affecting the vascular and respiratory systems of man, the various pathogenic trypanosomes of man and transport animals, and various parasites of birds, fish, and insects; he also continued his researches on the "bee disease." Dr. D. Thomson visited Panama and British Guiana to make observation of the sanitation of these places, and since then he has been engaged with Dr. J. G. Thomson in the cultivation of malarial parasites *in vitro.* Dr. Fantham in 1912, at the invitation of the Anglo-Egyptian Government, visited Khartoum and brought back with him much valuable material.

Laboratory and Field Work in the Colonies.

British Guiana.—Investigations were made by Dr. K. S. Wise and Dr. E. P. Minett on (1) aspergillar mycosis, (2) septicæmia and filaria bancrofti, (3) epidermophyton cruris, and (4) epidemic dropsy. Interesting facts are given as to this last-named disease, which broke out among the carriers of an expedition into the interior. The occurrence of this malady was attributed to the long-continued use of dried and tinned foods, leading to a deficiency of certain substances essential for maintaining health.

Ceylon.—Dr. A. Castellani carried out researches on (1) a new intestinal protozoal parasite causing dysenteric symptoms; (2) peculiar bodies found in a case of tropical splenomegaly with fever; (3) cases of pseudo-diphtheria due to fungi; (4) the plurality of species of the so-called thrush fungus; and (5) typhoid-paratyphoid vaccination with mixed vaccines.

Fiji.—The treatment of yaws and syphilis by salvarsan is discussed by Mr. P. T. Harper, who regards the use of this in yaws as economical since it shortens greatly the patient's stay in hospital. Mr. A. E. Ireland reports on the examination of certain specimens of rice in some of which the pericarp and in some also the subpericarpal layers had been removed wholly or in part in the process of milling, Siam rice being the most denuded. There had been, however, no beri-beri following the long-continued use of such rice, this being probably accounted for by the fact that dhal is invariably eaten with the rice.

Hong-Kong.—An investigation of the mosquitoes of this colony was carried out, special search being made for stegomyia fasciata, but practically this species is absent, S. scutellaris being the predominating species. As, however, S. fasciata exists in Japanese ports as well as in the Philippines and Singapore, with which Hong-Kong is in communication by shipping, there is a possibility of its importation.

Jamaica.—Dr. H. H. Scott made a number of investigations on enteric fever, ankylostomiasis, dysentery, and "vomiting sickness," details of which are given. As regards the last-named disease, he puts forward evidence to disprove its relationship with yellow fever; on bacteriological grounds he shows that some of the reported cases were suffering from cerebro-spinal fever. Dr. W. D. Neish contributes a report on the tabanidæ of Jamaica, and gives notes on malaria and ankylostomiasis.

Leeward Islands.—The medical officers of St. Kitts report on the treatment of yaws by salvarsan, the average stay in hospital being reduced by it to 21 days. One case of filariasis was also treated by salvarsan, and has progressed favourably since he received two injections.

Malay States.—In the Institute for Medical Research, of which Dr. H. Fraser is director, attempts were made to cultivate the leprosy bacillus but without success, though the technique, described by those who claim to have succeeded, was carefully followed.[2] Dr. W. Fletcher continued his researches on blackwater fever, and Dr. A. T. Stanton made investigation into the anopheles mosquitoes of Malaya and their larvæ; he also inquired into the changes which occur in certain characters of these larvæ in the course of their growth. Mr. J. D. Gimlette reports on beri-beri in Kelantan, and we gather that he holds the view that rice "acts only as a vehicle" of the poison and not as a "causative agent" of the disease.

Sierra Leone.—Among the reports furnished are several on the splenic index in some of the districts. Dr. J. W. Collett investigated the subject of dried vaccine lymph; he prefers a lanolated calf lymph. Dr. J. Y. Wood gives notes on 257 cases of goitre collected in the Koinadugu district in a period of six months.

Trinidad.—Dr. F. L. de Verteuil reports on cases in the leper hospital, and states that he finds nastin valuable in instances where there is no ulceration, especially when it is combined with antileprol; but to be successful the treatment must be continued for two years or more, whereas most patients give up the remedy after a few months' trial.

Windward Islands.—Some 245 cases of yaws were treated with salvarsan, of which 229 were discharged from the hospital as cured; 12 cases, or 5 per cent., had a relapse within three months, but it is probable they had not received a sufficient dose of the drug. It appears that the natives apply eagerly for the treatment, and if there had been a regular and adequate supply of salvarsan available the number of cases treated would have far exceeded the number stated above.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the thirty-first meeting of the Royal Commission on Venereal Diseases evidence was given by Mr. F. Richardson Cross, one of the representatives before the Commission of the Royal College of Surgeons of England. Mr. Cross dealt principally with the effects of venereal diseases upon the eye. He described the serious results which venereal diseases produced in this connexion, and expressed the opinion that a large proportion of the cases of blindness were due to these diseases. He was not able to give complete statistics on this point, but he gave as an example an examination conducted at a blind school which showed that blindness was due to ophthalmia neonatorum in 47 cases out of 102. He also referred to the results of an investigation at a French institution which suggested that out of 625 cases of blindness 325 were traceable to venereal disease. Mr. Cross considered that the importance of venereal diseases was only realised by a very limited number of people, and he thought that the medical profession ought to instruct the public. It should be pointed out that any of these forms of disease were not local things which would pass off, but that the individual might be stamped for life with it, and that it might go down to his or her posterity. It was necessary that the knowledge should be spread very tactfully, but it ought to be done.

---

[2] THE LANCET, Sept. 27th, 1913, p. 913.

Mr. Cross alluded to the importance of early diagnosis and energetic and satisfactory treatment of these diseases, and urged that some assistance should be given by the State. He did not think that the Insurance Act touched this matter at all. The doctor under the Insurance Act could not be expected to make a scientific investigation, and neither he nor the chemist could afford the expense of injections of salvarsan. Laboratories in which tests could be made for purposes of diagnosis should be subsidised and developed, and grants should also be made to assist treatment by hospitals. He was not in favour of special hospitals for venereal diseases, but thought that persons suffering from them should be treated among the ordinary patients as far as possible. It ought to be made easy for people to get thorough treatment for these diseases, and it would be an advantage if evening clinics could be established to deal with them.

At the thirty-second meeting Dr. C. T. Parsons, medical superintendent of the Fulham Poor-law Infirmary, gave evidence. Dr. Parsons described the treatment he had adopted, which followed the lines of that used at the Rochester-row Hospital. Salvarsan or neosalvarsan had been used at the Fulham Infirmary since April, 1911. The experience had been that most lesions healed very rapidly under its influence. The results had been most striking in cases of acquired syphilis, and had been less successful in the case of congenital syphilis, while only temporary relief of symptoms had been obtained in the case of para-syphilitic conditions. On the whole neosalvarsan had been found to be better tolerated but less efficacious than salvarsan. No bad results of a serious character had followed the injections. The only difficulty in carrying out the treatment had been in inducing patients to submit to it and to remain until it was completed. A few patients refused to have any injection after the first, and some insisted upon taking their discharge directly the lesions had healed.

Dr. Parsons said that one of the greatest needs of the Poor-law infirmary in connexion with the treatment of venereal diseases was the provision of facilities for bacteriological examinations and the carrying out of Wassermann tests.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 18,120,059 persons, 9467 births and 5259 deaths were registered during the week ended Saturday, April 25th. The annual rate of mortality in these towns, which had declined from 16·5 to 14·9 per 1000 in the four preceding weeks, rose to 15·1 per 1000 in the week under review. Among the several towns the death-rate ranged from 4·7 in Eastbourne, 4·9 in Swindon, 6·9 in Ilford, 7·3 in Edmonton, and 7·5 in Reading, to 21·1 in Plymouth and in Dudley, 21·8 in Great Yarmouth, 23·1 in Dewsbury, and 23·5 in Stoke-on-Trent.

The 5259 deaths from all causes were 67 in excess of the number in the previous week, and included 445 which were referred to the principal epidemic diseases, against 433 and 438 in the two preceding weeks. Of these 445 deaths, 166 resulted from whooping-cough, 140 from measles, 66 from infantile diarrhœal diseases, 40 from diphtheria, 23 from scarlet fever, and 10 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3, against 1·2 and 1·3 per 1000 in the two preceding weeks. The deaths attributed to whooping-cough, which had been 172, 150, and 117 in the three preceding weeks, rose to 166 last week, and caused the highest annual death-rates of 1·3 in Leicester, 1·4 in Sheffield, 1·6 in Rotherham, 1·7 in Tynemouth and in Swansea, 1·9 in Cardiff, and 2·1 in Middlesbrough. The deaths referred to measles, which had been 137, 134, and 153 in the three preceding weeks, fell to 140 last week; the highest death-rates from this cause were 1·7 in Sheffield, 1·8 in Merthyr Tydfil, 1·9 in Burnley, 2·0 in Leicester, and 3·0 in Dudley. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 77, 54, and 61 in the three preceding weeks, further rose to 66 last week, of which 18 were registered in London, 4 in Birmingham, 4 in Liverpool, 4 in Manchester, and 3 each in Stockport, Birkenhead, Middlesbrough, and Newcastle-on-Tyne. The deaths attributed to diphtheria, which had been 51, 44, and 50 in the three preceding weeks, declined to 40 last week, and included 10 in London, 3 in Coventry, and 2 each in Portsmouth, Stoke-on-Trent, Birmingham, Leicester, Liverpool, and Salford. The deaths referred to scarlet fever, which had increased from 33 to 40 in the four preceding weeks, fell to 23 last week; 5 deaths were recorded in London, 4 in Birmingham, and 2 each in Manchester, Salford, and Sheffield. The fatal cases of enteric fever, which had been 12, 12, and 17 in the three preceding weeks, declined to 10 last week, of which 2 occurred in London.

The number of scarlet fever patients under treatment in the London Fever and the Metropolitan Asylums Hospitals, which had been 3182, 3068, and 2992 at the end of the three preceding weeks, had further declined to 2886 on Saturday last; 305 new cases were admitted during the week, against 399, 306, and 289 in the three preceding weeks. These hospitals also contained on Saturday last 1141 cases of diphtheria, 356 of whooping-cough, 101 of measles, and 57 of enteric fever, but not one of small-pox. The 1248 deaths from all causes in London were 7 fewer than the number in the previous week, and corresponded to an annual death-rate of 14·4 per 1000. The deaths referred to diseases of the respiratory system, which had been 280, 219, and 263 in the three preceding weeks, fell to 258, and were 71 below the number registered in the corresponding week of last year.

Of the 5259 deaths from all causes in the 97 towns, 193 resulted from various forms of violence, and 408 were the subject of coroners' inquests, while 1527 occurred in public institutions. The causes of 35, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Bristol, Hull, Nottingham, Salford, and in 55 other smaller towns. Of the 35 uncertified causes of death, 8 were recorded in Birmingham, 3 in Gateshead, and 2 each in Stoke-on-Trent, Liverpool, Bootle, and Blackburn.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1359 births and 702 deaths were registered during the week ended Saturday, April 18th. The annual rate of mortality in these towns, which had been 16·5, 18·6, and 16·5 per 1000 in the three preceding weeks, further declined to 16·0 per 1000 in the week under notice, against an average rate of 18·2 in the 13 weeks of last quarter. Among the several towns the death-rate ranged from 8·8 in Motherwell, 11·8 in Leith, and 12·1 in Dundee, to 19·0 in Kirkcaldy, 21·8 in Coatbridge, and 22·0 in Ayr.

The 702 deaths from all causes were 25 fewer than the number in the previous week, and included 55 which were referred to the principal epidemic diseases, against 81 and 65 in the two preceding weeks. Of these 55 deaths, 20 resulted from measles, 13 from infantile diarrhœal diseases, 11 from whooping-cough, 7 from scarlet fever, and 4 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1·3 per 1000, and coincided with the rate recorded in the 97 large English towns during the same week. The deaths attributed to measles, which had been 34, 37, and 31 in the three preceding weeks, further fell to 20, and comprised 15 in Glasgow, 3 in Ayr, and 2 in Edinburgh. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 14, 14, and 5 in the three preceding weeks, rose to 13, of which 6 were recorded in Glasgow, 2 in Dundee, and 2 in Aberdeen. The fatal cases of whooping-cough, which had been 11, 15, and 12 in the three preceding weeks, were 11, and included 5 in Glasgow and 3 in Coatbridge. The 7 deaths attributed to scarlet fever, of which 5 occurred in Glasgow, were slightly below the weekly average in the preceding quarter. The fatal cases of diphtheria, which had been 9, 9, and 7 in the three preceding weeks, further declined to 4, and comprised 2 in Glasgow, 1 in Edinburgh, and 1 in Aberdeen.

The deaths referred to diseases of the respiratory system, which had been 111, 166, and 137 in the three preceding weeks, further fell to 120 in the week under notice; and 29 deaths resulted from various forms of violence, against 33 and 28 in the two preceding weeks.

In the 16 largest Scotch towns 1236 births and 741 deaths were registered during the week ended Saturday, April 25th. The annual rate of mortality in these towns, which had been 18·6, 16·5, and 16·0 per 1000 in the three preceding weeks, rose to 16·9 per 1000 in the week under review. Among the several towns the death-rate ranged from 7·7 in Perth, 7·8 in Falkirk, and 12·6 in Motherwell, to 21·6 in Hamilton, 21·9 in Aberdeen, and 23·6 in Ayr.

The 741 deaths from all causes were 39 in excess of the number in the previous week, and included 71 which were referred to the principal epidemic diseases, against numbers decreasing from 81 to 55 in the three preceding weeks. Of these 71 deaths, 29 resulted from measles, 18 from infantile diarrhœal diseases, 9 from whooping-cough, 9 from diphtheria, 4 from scarlet fever, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·6, against 1·3 per 1000 in the 97 large English towns. The deaths attributed to measles, which had been 37, 31, and 20 in the three preceding weeks, rose to 29 last week, of which 20 occurred in Glasgow, 3 in Edinburgh, and 3 in Hamilton. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 14, 5, and 13 in the three preceding weeks, further rose to 18, and included 10 in Glasgow and 2 in Kilmarnock. The fatal cases of whooping-cough, which had been 15, 12, and 11 in the three preceding weeks, further declined to 9, and comprised 8 in Glasgow and 1 in Coatbridge. The deaths attributed to diphtheria, which had been 9, 7, and 4 in the three preceding weeks, rose to 9 last week, of which 4 occurred in Glasgow, 2 in Edinburgh, and 2 in Kilmarnock. The deaths referred to scarlet fever, which had been 4, 6, and 7 in the three preceding weeks, fell to 4 last week, of which 2 were registered in Glasgow. The 2 fatal cases of enteric fever were recorded in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 166, 137, and 120 in the three preceding weeks, rose to 130 in the week under review; and 31 deaths resulted from various forms of violence, against 28 and 29 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,205,280 persons at the middle of this year, 673 births and 584 deaths were registered during the week ended Saturday, April 25th. The annual rate of mortality in these towns, which had been 21·7, 20·3, and 22·5 per 1000 in the three preceding weeks, rose to 25·3 per 1000 in the week under notice, against corresponding rates of 15·1 and 16·9 in the English and Scotch towns respectively. The death-rate was equal to 27·9 in Dublin (against 16·9 in Glasgow and 14·4 in London), 23·4 in Belfast, 33·3 in Cork, 16·5 in Londonderry, 28·4 in Limerick, and 24·7 in Waterford, while in the 21 smaller towns the mean rate was 22·2 per 1000.

The 584 deaths from all causes were 65 in excess of the number in the previous week, and included 69 which were referred to the principal epidemic diseases, against numbers increasing from 48 to 75 in the three preceding weeks. Of these 69 deaths, 37 resulted from measles, 12 from whooping-cough, 7 from scarlet fever, 7 from infantile diarrhœal diseases, 3 from diphtheria, and 3 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3·0, against corresponding rates of 1·3 and 1·6 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 26, 37, and 42 in the three preceding weeks, fell to 37 last week, of which 35 occurred in Dublin. The deaths referred to whooping-cough, which had been 10, 9, and 14 in the three preceding weeks, fell to 12, and included 8 in Belfast and 2 in Dublin. The 7 fatal cases of scarlet fever, of which 6 were registered in Belfast, were 2 in excess of the average in the four preceding weeks. The deaths of infants (under 2 years), attributed to diarrhœa and enteritis, which had been 6, 8, and 10 in the three preceding weeks, declined to 7, and included 3 in Dublin and 2 in Belfast. The 3 deaths referred to diphtheria, which were all recorded in Dublin, were equal to the average number in the four preceding weeks. The 3 fatal cases of enteric fever occurred in Cork. Lisburn, and Ballymena.

The deaths referred to diseases of the respiratory system, which had been 118, 102, and 115 in the three preceding weeks, fell to 112 in the week under notice. Of the 584 deaths from all causes, 192, or 33 per cent., occurred in public institutions and 10 resulted from various forms of violence. The causes of 23, or 3·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 large English towns the proportion of uncertified causes last week did not exceed 0·7 per cent.

VITAL STATISTICS OF LONDON DURING MARCH, 1914.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 7·4 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding months the rates were 9·0, 8·3, and 8·5 per 1000 respectively. The lowest rates in the month were recorded in Chelsea, the City of Westminster, St. Marylebone, Holborn, Finsbury, Shoreditch, and Stepney; and the highest rates in Hammersmith, Fulham, Hampstead, Southwark, Greenwich, and Woolwich. Scarlet fever was less prevalent than it had been in the preceding month; the greatest proportional prevalence of this disease was recorded in Hammersmith, Fulham, Southwark, Lambeth, Deptford, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 3810, 3543, and 3328 at the end of the three preceding months, had further declined to 3138 at the end of the month; the weekly admissions averaged 337, against 445, 400, and 379 in the three preceding months. The prevalence of diphtheria also showed a slight decrease as compared with that in the preceding month; this disease was proportionally most prevalent in Hampstead, Southwark, Battersea, Greenwich, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 1306 diphtheria patients at the end of the month, against 1099, 1092, and 1225 at the end of the three preceding months; the weekly admissions averaged 158, against 146, 153, and 166 in the three preceding months. The prevalence of enteric fever showed a very considerable decline as compared with that in other recent months; among the several metropolitan boroughs this disease was proportionally most prevalent in Fulham, Chelsea, the City of Westminster, Islington, Bethnal Green, Southwark, and Greenwich. There were 66 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 51, 65, and 82 at the end of the three preceding months; the weekly admissions averaged 6, against 9, 14, and 15 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Finsbury, Shoreditch, Bethnal Green, and Southwark. The 43 cases of puerperal fever notified during the month included 5 in Shoreditch, 5 in Wandsworth, 4 in Fulham, 4 in Islington, 4 in Lambeth, and 3 in St. Marylebone. Of the 10 cases of cerebro-spinal meningitis, 2 belonged to Poplar, and the 3 cases of poliomyelitis belonged respectively to Paddington, Islington, and Stepney.

The mortality statistics relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates for all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the five weeks ending April 4th the deaths of 6591 London residents were registered, equal to an annual rate of 15·2 per 1000; in the three preceding months the rates had been 14·9, 18·4, and 14·8 per 1000 respectively. The death-rates for the month ranged from 10·1 in Lewisham, 10·7 in Wandsworth, 10·9 in Hampstead, 11·7 in Kensington, and 13·1 in Stoke Newington, to 18·0 in Finsbury, 18·1 in Bethnal Green, 18·4 in Poplar, 19·2 in Shoreditch and in Southwark, and 20·3 in the City of London. The 6591 deaths from all causes included 415 which were referred to the principal infectious diseases; of these, 79 resulted from measles, 33 from scarlet fever, 61 from diphtheria, 138 from whooping-cough, 12 from enteric fever, and 92 from diarrhœa and enteritis among children under two years of age. The lowest death-rates in the month from these infectious diseases were recorded in Paddington, Kensington, Stoke Newington, Battersea, and Lewisham; and the highest rates in St. Pancras, Bethnal Green, Poplar, Camberwell, Deptford, and Greenwich. The 79 fatal cases of measles were 310 fewer than the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Finsbury, Stepney, Bermondsey, Camberwell, Deptford, and Greenwich. The 33 deaths from scarlet fever were 12 in excess of the corrected average number; the greatest proportional mortality from this disease occurred in Kensington, St. Pancras, Islington, Poplar, Southwark, Lambeth, and Camberwell. The 61 fatal cases of diphtheria were 4 above the corrected average number; the highest death-rates from this disease were recorded in Hammersmith, Chelsea, Finsbury, Bethnal Green, Poplar, Bermondsey, and Woolwich. The 138 deaths from whooping-cough were 34 fewer than the corrected average number; this disease was proportionally most fatal in St. Marylebone, Hampstead, St. Pancras, Hackney, Shoreditch, Bethnal Green, Poplar, and Southwark. The 12 deaths from enteric fever were slightly in excess of the corrected average number, and included 2 in Islington, 2 in Poplar, and 2 in Greenwich. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Hammersmith, St. Marylebone, Hackney, Bethnal Green, Poplar, Lambeth, and Camberwell. In conclusion, it may be stated that the aggregate mortality in London during the month under notice from the principal infectious diseases, excluding diarrhœa, was 41·3 per cent. below the average.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MARCH, 1914.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Surgeon-General: W. H. Norman to the *Vivid*, additional, for Plymouth Hospital. Fleet-Surgeons: J. McElwee to the *Egmont*, additional, for Malta Dockyard; and E. Cooper to the *Carnarron*. Staff-Surgeons: A. I. Sheldon to the *Philomel*, on recommissioning, for service under New Zealand Government; R. R. Horley to the *Psyche*, additional, and on recommissioning; and J. Bourdas to the *Hearty*. Surgeons: B. Taylor to the *Triumph*, additional, for Hong-Kong Hospital; and C. M. R. Thatcher to the *Dreadnought*.

ARMY MEDICAL SERVICE.

Colonel M. W. O'Keeffe, on completion of four years' service in his rank, is placed on the half-pay list (dated April 23rd, 1914).

Lieutenant-Colonel Charles C. Reilly, from the Royal Army Medical Corps, to be Colonel, vice M. W. O'Keeffe (dated April 23rd, 1914).

ROYAL ARMY MEDICAL CORPS.

Surgeon-General Sir A. T. Sloggett, C.B., C.M.G., has arrived home from India on transfer to the Home Establishment.

Colonel R. W. Ford, D.S.O., has been appointed Deputy Director of Medical Services to the Aldershot Command.

Brevet-Colonel F. Smith, D.S.O., has been selected for appointment as Medical Inspector of Recruits on the Headquarters Staff of the Irish Command. Brevet-Colonel S. Hickson has been transferred to the London District.

Lieutenant-Colonel R. J. Windle has been selected for the higher grade of his rank for promotion. Lieutenant-Colonel J. C. Connor has arrived home from India for duty in the Irish Command. Lieutenant-Colonel M. P. C. Holt, D.S.O., has been appointed to hold charge of the Cambridge Military Hospital at Aldershot. Lieutenant-Colonel W. Turner has been appointed Deputy Assistant Director of Medical Services to the Welsh Division. Lieutenant-Colonel G. H. Barefoot has taken over charge of Queen Alexandra's Military Hospital. Lieutenant-Colonel J. H. Daly has been appointed Senior Medical Officer of the North Irish Coast Defences. Lieutenant-Colonel H. D. Rowan has been appointed to hold charge of King George V. Military Hospital at Dublin.

Major H. P. W. Barrow has arrived home for duty from Jamaica. Major H. M. Nicholls has been appointed to the Scottish Command. Major M. H. G. Fell has joined at Aldershot. Major P. S. Lelean has taken up duty at the Royal Army Medical College as Assistant Professor of Military Hygiene and Sanitation. Major E. T. Inkson, V.C., has arrived home for duty from India. Major W. L. Baker has been appointed to the London District. Major R. B. Black has arrived home on leave of absence. Major M. O. Wilson has joined the Eastern Command. Major W. J. Taylor has arrived home for duty from the Sierra Leone Protectorate. Major M. Leckie has been appointed to the Southern Command. Major G. J. A. Ormsby has been appointed to the Dublin District. Major F. E. Gunter has been transferred from the Military Hospital at Tidworth to the Royal Military College at Sandhurst. Major G. Baillie has been placed under orders to officiate in charge of the Military Hospital at Ipswich. Major J. F. Martin has been transferred from the Royal Military College at Sandhurst to the Aldershot Command. Major A. C. Adderley has been appointed Company Officer to No. 22 Company of the Royal Army Medical Corps at Wynberg, Cape Colony.

Captain W. C. Nimmo has been appointed Specialist in Midwifery and Diseases of Women and Children, and placed in charge of Military Families Hospital at Aldershot. Captain S. Field has arrived home for duty from Jamaica. Captain A. G. Wells has been appointed to the Scottish Command. Captain G. H. J. Brown has been appointed in charge of the Military Hospital at Aberdeen. Captain C. Bramhall has taken up duty as Adjutant of the Royal Army Medical Corps School of Instruction at Manchester. Captain D. Ahern has joined at Dublin. Captain O. R. McEwen has arrived home for duty from India. Captain R. M. Davies has been appointed to hold medical charge of the Detention Barracks at Headquarters, Pretoria. Captain W. A. Spong has arrived home on leave of absence. Captain R. J. C. Thompson has been appointed to the Southern Command. Captain H. C. Hildreth has been appointed to hold charge of the Military Families Hospital at Fermoy. Captain T. S. Eves has been appointed Staff-Surgeon at Lucknow. Captain J. T. McEntire has been appointed to the Irish Command. Captain P. G. M. Elvery has joined at Cairo for a tour of duty on the staff of the Military Hospital. Captain H. S. Dickson has been selected for appointment as Embarkation Medical Officer at Gibraltar. Captain R. Gale has joined the Public Health Department in Egypt. Captain C. W. Holden has joined the London District. Captain W. E. C. Lunn has arrived home from Lahore Cantonment. Captain W. E. Marshall has been transferred from the Military Hospital at Cork to Kinsale. Captain M. G. Dill has been appointed to hold charge of the Military Hospital at Ayr. Captain J. C. L. Hingston has been appointed Specialist in Dermatology and Venereal Diseases to the Burma Division. Captain M. J. Williamson has been transferred from the Military Hospital at Potchefstroom to Wynberg. Captain J. H. Douglass has been appointed Specialist Sanitary Officer in Sierra Leone Protectorate. Captain C. M. Nichol has been transferred from the Military Hospital at Cairo to Alexandria. Captain F. Worthington has been appointed to Gravesend. Captain J. H. Duguid has been appointed Specialist in Otology to the Military Hospital at Secunderabad Cantonment. Captain A. Shepherd has been transferred from the Military Hospital at Rangoon to Shwebo Cantonment. Captain N. Low has taken up duty at Colchester on transfer from the Military Hospital at Golden Hill. Captain J. R. Lloyd has been appointed to hold charge of the Section Hospital at the Crater, Aden. Captain R. P. Lewis has been appointed Specialist in Physical Training to the Aldershot Command. Captain G. W. G. Hughes has been appointed Specialist in Ophthalmology to the Military Hospital at Plymouth. Captain A. T. Frost has been transferred from the Military Hospital at Calcutta to Lucknow Cantonment.

Lieutenant E. G. S. Cane has been appointed Specialist in the Prevention of Disease to the Bombay Brigade and placed in charge of the Bacteriological Research Laboratory at the Military Hospital, Colaba. Lieutenant C. J. H. Little has been appointed to the Military Hospital at Rawal Pindi Cantonment. Lieutenant H. J. S. Shields has been transferred from the London District to the Military Hospital at Caterham. Lieutenant R. C. Carlyle has embarked for Malta. Lieutenant G. F. Allison has been appointed Company Officer to No. 8 Company, Royal Army Medical Corps, at York. Lieutenant D. Reynolds has been appointed to hold charge of the Military Hospital at Attock Cantonment. Lieutenant E. P. A. Smith has joined at Lucknow Cantonment.

INDIAN MEDICAL SERVICE.

Colonel P. Hehir has been transferred from the Sixth (Poona) Division and appointed to officiate as Deputy Director of Medical Services at Army Headquarters, Simla.

Lieutenant-Colonel F. J. Dewes has been appointed Civil Surgeon at Myingyan. Lieutenant-Colonel C. MacTaggart, C.I.E., has been selected for appointment as Officiating Inspector-General of Civil Hospitals in the United Provinces of Agra and Oudh, *pro tem.* Lieutenant-Colonel S. E. Prall has arrived home on leave of absence from India. Lieutenant-Colonel E. Hudson has been appointed Superintendent of the Central Prison at Allahabad. Lieutenant-Colonel R. H. Castor has been appointed to the Civil Medical Department in Burma. Lieutenant-Colonel R. C. Macwatt has been appointed Civil Surgeon at Ajmer. Lieutenant-Colonel A. R. S. Anderson has joined at Dacca.

Major J. G. P. Murray, officiating civil surgeon at Cuttack, has been granted three months' leave of absence. Major G. Y. C. Hunter has been appointed to the Jail Department in Bihar. Major A. H. Moorhead has been appointed to hold substantive medical charge of the 16th Cavalry. Major W. F. Harvey has arrived home on leave of absence from India. Major T. H. Delany has been appointed Civil Surgeon at Saran.

Captain H. Watts, officiating civil surgeon at Betal, has been granted three months' leave of absence. Captain D. G. Rai has been appointed District Medical and Sanitary Officer at Arcot and Nellore. Captain F. A. F. Barnado has been appointed to officiate in the Civil Medical Department, Bengal Presidency. Captain A. K. Lauddie has joined the Jail Department in Ludhiana. Captain B. F. Steel has been granted two years' leave of absence home from India. Captain H. R. B. Gibson has arrived home on leave of absence from India. Captain R. M. Barron has been appointed to hold substantive medical charge of the 32nd Lancers. Captain J. McPherson has been appointed an Agency Surgeon under the Foreign Department of the Government of India. Captain F. C. Rogers has been appointed Sanitary Officer at Kurnool. Captain W. R. J. Scroggie has taken up duty in the Civil Medical Department of Madras Presidency. Captain J. H. Burgess has been appointed Surgeon to the Governor of Bengal. Captain J. W. Illius has taken up duty as District Medical and Sanitary Officer at Arcot. Captain H. H. G. Knapp has been appointed Superintendent of the Central Jail at Rangoon. Captain W. H. Odlum has been appointed to hold substantive medical charge of the 30th Lancers.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Captain Samuel M. Sloan resigns his commission (dated April 25th, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd East Lancashire Field Ambulance, Royal Army Medical Corps: Arthur Morrell Johnson to be Lieutenant (dated March 16th, 1914).

3rd Lowland Field Ambulance, Royal Army Medical Corps: Robert Balfour Barnetson to be Lieutenant (dated April 29th, 1914).

For attachment to Units other than Medical Units.—Samuel Macfarlane Sloan (late Captain, Special Reserve, Royal Army Medical Corps), to be Captain (dated April 25th, 1914); and Harold Seddon to be Lieutenant (dated Feb. 1st, 1914).

Attached to Units other than Medical Units.—Lieutenant John Graham to be Captain (dated Nov. 7th, 1913). Captain William W. Jones to be Major (dated Dec. 1st, 1913). Lieutenant Charles H. Caldicott to be Captain (dated Jan. 22nd, 1914). Captain Walter R. N. Smithard to be Major (dated March 17th, 1914). Captain William S. Paterson resigns his commission (dated April 29th, 1914).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Major William Watkins Jones, from the list of Officers attached to Units other than Medical Units, to be Major (dated Dec. 1st, 1913).

ARCHIVES DE MÉDECINE ET DE PHARMACIE NAVALES.

In the February number Dr. Chastang, principal medical officer of the French squadron in China, discusses the question of venereal prophylaxis, and tells us that the incidence of these diseases in that squadron (137 cases per 1000 men per annum) is double that (63) observed in the fleet at home. This greater prevalence he ascribes to two causes—the vast number of prostitutes everywhere in Asia, and the relative dulness of the lives of the seamen. He gives information regarding the prevalence of venereal disease in Japan when he quotes figures showing that in 1911 48,105 public women were examined on 2,839,810 occasions, when 34,538 cases of gonorrhœa and its sequelæ were observed, 17,561 of soft chancre, and 3837 syphilitic manifestations (each woman examined some 59 times, and the relative prevalence of disease—gonorrhœa 62, soft sores 31, and syphilis 7 per cent.). Considering that to some extent the men are driven to associate with prostitutes for want of other amusements, Dr. Chastang recommends games to them—football, gymnastics, tennis—and tells us that one group of men in China ceased to develop cases of venereal disease when their officers incited them to play games. As to therapeutic prophylaxis, it was ordered in the French navy in 1909, but medical officers have not been busy to see it was carried out. Encouraged by their principal medical officer several French naval doctors in China have taken more hold of this question, besides they say they have found it well handled in the British and German ships lying alongside them. So now proper arrangements are made, the men who contract venereal disease, but have not reported their risk and taken the treatment, are punished, and we are given stories to read of the immediate decrease of cases, very similar to those that were so frequently being told from the United States Service a few years ago. Dr. Chastang is of opinion that venereal prophylaxis will always be successful if the ship's medical officer is convinced it is a good thing and determines it shall be used. Its success then in any ship might well be considered as a claim by her medical officer for his promotion. At the end of the number are reports of a great many cases of tropical fevers of uncertain origin, spoken of as three, four, seven, and ten day fevers, and one is struck by the great need there is for adding a blood count, at least a differential leucocyte count, to every clinical report on a tropical or any other fever. We have heard that in South-Eastern Europe women are definitely assigned by the War Office to some of the supply services on mobilisation, but what is the French Admiralty doing (p. 157) issuing orders about "Rest for women before childbed." Perhaps of course it is to apply only in the dockyards, not in the service afloat.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on April 21st, the Medical Director-General of the Navy in the chair, the sum of £40 was distributed among the several applicants.

ROYAL INSTITUTION.—On Tuesday next, May 5th, at 3 o'clock, Professor W. Bateson will deliver the first of two lectures at the R[illegible] (1) Double [illegible]oyal Institution on [illegible]ry. Flowers and (2) the Present State of Evolutionary Theory. The Friday evening discourse on May 8th will be delivered by Professor Karl Pearson on Albinism in Men and Dogs, and on May 15th by Professor Frederick Keeble on Plant Animals: a Study in Symbiosis.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

LIVERPOOL.

Tropical Medicine.

WITH a view to carrying on research work in its various branches the School of Tropical Medicine intends to establish a permanent laboratory on the West Coast of Africa. The colony of Sierra Leone has been selected for this purpose. It possesses special advantages for such work, as there is ample material for the study of tropical diseases, and being one of the nearest tropical colonies to England, is accessible more rapidly and cheaply than any other suitable place in the tropics. It is hoped that the laboratory will act as a base from which expeditions may be despatched from time to time to other regions of tropical Africa.

St. Helens Hospital.

The annual meeting of the St. Helens Hospital was held on April 23rd. The Mayor (Sir David Gamble), who presided, referred appreciatively to the work of their first and late President, Colonel W. W. Pilkington. It was unanimously agreed to ask Mr. Richard Austin Pilkington to succeed his father as President. The forty-first yearly report stated that the income for the year amounted to £5919, and the expenditure to £5145. The 1*d.* a week subscription showed a gratifying increase; £4515 had been raised in this manner, being £376 in excess of last year. The number of patients admitted during the year was 1228, compared with 1179 patients in hospital in 1912.

Doctor's Widow's Action.

Mrs. Amy Louisa O'Donoghue, the widow of Mr. William Charles O'Donoghue, brought an action against the Cheshire Lines Committee to recover damages for herself and her infant children in respect of the loss of her husband. The case was tried at the Liverpool Assizes on April 23rd before Mr. Justice Ridley. In December last Mr. O'Donoghue was returning to Liverpool from Manchester by train. He was seized with sickness and put his head out of the window for a few minutes. While he was in this position a local train passed on an adjoining line and an open swinging door in one of the carriages struck him on the head and killed him instantly. Mr. Rigby Swift, K.C., M.P., for the plaintiff, said everyone knew there were certain *risks* about putting one's head out of a carriage window, but a railway door carelessly left open was not a risk which must be reasonably contemplated. There were no circumstances which could more strongly justify a passenger *acting* in that way than the circumstances related in this case. Mr. Gordon Stewart, K.C., M.P., for the defence, argued that the deceased had been negligent in thrusting his head so far out of the window. Mr. O'Donoghue was subject to train sickness and ought *to* have been prepared for its oncoming and should have gone to the window on the near side where no trains would pass. His lordship said he could not get himself to see in what duty the railway company had failed in regard to a passenger in other train when *nothing* could have happened him if he had kept his head indoors as he intended to do. Mr. Swift argued that the doctor's action was not a negligent one, because he happened to be sick, but that was not the way to measure the reasonableness of the act. "I have been in steamboats, and I daresay members of the jury have too," went on his lordship, "when five or six people in the same cabin have all been sick one after the other. Did any of them take the trouble to go to the side? No, they were all sick in the presence of each other. It cannot seriously be put forward that because there were others present a man is justified in taking on himself the risk of thrusting his head through the window. If the train were stationary and no other train was approaching, of course a gentleman would take means to avoid giving trouble to his fellow passengers." The jury found that the defendants had been guilty of negligence in allowing the door to be open, and that the deceased was not negligent in putting his head out of the window and keeping it there in the circumstances. They awarded £2750 damages in all, £1250 for the widow and £500 for each of the three children. Mr. Justice Ridley: "I entirely disagree with the verdict, but I will grant a stay without any terms."

April 28th.

BRISTOL AND WESTERN COUNTIES.

Lord Mayor's Hospital Sunday Fund.

THE total sum collected up to now amounts to £2041 4s. 1d., a figure only exceeded on two previous occasions, both of them in the last decade. There are still a few collections to come in, so that it is possible that this year's total may reach second place. In view of the very natural apprehensions that were expressed as to the effect of the National Insurance Act on this and similar funds, so successful a result is particularly gratifying.

Tuberculosis Dispensaries in Bristol.

The Bristol tuberculosis scheme will shortly take a fresh step towards completion. A second dispensary is to be opened in the east central district to supplement the work that is already being carried on at the municipal dispensary in the south-west of the city. This will necessitate the appointment of a second whole-time tuberculosis officer.

Medical Inspection of School Children in Gloucestershire.

At a recent meeting of the Gloucestershire county council the remarkable statement was made that only about 40 per cent. of the children examined were normal. This raises the question, "What is normal?" It was not this, however, that agitated the council, but a straight hint from the Board of Education to the effect that the small percentage of reported children securing successful treatment rendered some better system necessary if certain maximum grants were to be secured. Something is proposed in the way of dental treatment, and an extension of the plan by which the recommendations of the school medical officer are carried out by visiting nurses is also mooted.

University of Bristol Colston Research Society.

The subscriptions to this society during the past year amounted to £505, and a sum of £300 was handed to the University for expenditure on research. The committee controlling the allocation of these funds to various researches has been enlarged by the addition of six members of Senate, and the president of the society is to be president *ex-officio* of the committee during his year of office.

Winsley Sanatorium.

At the annual meeting of supporters a curious state of affairs was disclosed in regard to this institution. As is known, it was opened some years ago as a private venture, with a certain number of its beds reserved for public bodies who contributed proportionate sums to its upkeep. Gradually the demand for this type of bed has increased, and it was recently proposed that more beds still should be allotted to public authorities. This proposal was carried, in spite of the strong disapproval expressed by a section of the managing board; but the execution of the plan was delayed by a request from the Charity Commissioners for the title deeds of the sanatorium, backed by a refusal on the part of the Local Government Board to sanction loans to public bodies to pay for the sanatorium beds which those authorities were under contract to purchase, unless the request of the Commissioners were acceded to. On inquiry the sanatorium management found that this difficulty did not arise from any dissatisfaction on the part of the Commissioners or the Board with the general management of the institution; however, the obstacle has not yet been removed. Apart from this the financial position is excellent; some very necessary extensions are being carried out, and a large legacy will allow of the erection of suitable premises for the resident medical officer. Since its opening there have been 1124 patients admitted to the sanatorium, 983 of whom came from Bristol. Of those discharged during the past year 53 per cent. were certified fit for some work.

Teignmouth and the Mussel Trade.

Dr. F. C. H. Piggott, medical officer of health for Teignmouth (Devon), in his annual report for 1913, states that the death-rate was 12·98 per 1000 and the birth-rate was 13·30. 50 per cent. of the children born during the year were vaccinated. Dr. Piggott, in alluding to the removal of the "embargo" on mussels gathered from the river Teign, mentions that the Fishmongers' Society had recommended that mussels should have a certificate stating that they had been "relaid" at Saltby for seven days, and if this certificate was not forthcoming the fish should be seized and condemned. He adds that there seemed to be a few reckless individuals who had distributed uncleaned mussels locally from the upper part of the river Teign, and these people by their selfish action had imperilled the whole trade.

The late Mr. Arthur John Awdry.

Mr. Arthur John Awdry, honorary medical officer to the Berkeley Hospital, who died at his residence, Berkeley, Gloucestershire, on April 23rd, from influenza followed by pneumonia, received his medical education at Birmingham University, and qualified L.R.C.P. and M.R.C.S. in 1901. He shortly afterwards joined his brother, Dr. W. R. Awdry, in partnership at Berkeley. He was extremely popular, and sympathy with his family is felt throughout the neighbourhood.

April 28th.

SCOTLAND.

The National Insurance Act and Aberdeen Doctors and Chemists.

ON April 22nd a largely attended meeting of Aberdeen doctors who are on the panel was held for the purpose of considering the deduction of 10 per cent. made from the payments to doctors under the National Insurance Act by the Aberdeen Burgh Insurance Committee. The finding of the meeting was ultimately embodied in the following resolution:—

That the Panel Committee be instructed to take legal advice in reference to the matter of deduction and to report.

It was also agreed to protest against the method of crediting to the Insurance Committees their share of the Medical Benefit Fund of Scotland. With regard to the county of Aberdeen, a final settlement has not been made with the doctors in respect of their payments, but it is understood there is still some money in hand, and no difficulty such as that existing in the city is anticipated. In the county the "floating sixpence" is available. In Aberdeen this has been absorbed to meet the drug bill, and a further total deduction in pharmaceutical charges of £620, or nearly as much as the 10 per cent. docking of the doctors' fees, has been made on the accounts rendered by the chemists, the chemists thus being 10 per cent. short of their legitimate payments. The amount available is £5000, the chemists' accounts have come to £5615, and there has been paid to chemists the sum of £4995.

Chancellorship of the University of Aberdeen.

At a statutory meeting of the general council of the University of Aberdeen held on April 18th, the Earl of Elgin and Kincardine was elected Chancellor of the University of Aberdeen. There were no other nominations. Lord Elgin has been pleased to accept office.

Diphtheria in Inverness.

Within the last fortnight a smart outbreak of diphtheria has occurred in Inverness, 26 cases having been notified. A large majority of these cases were found to have had their milk from one dairy, and the outbreak has been definitely traced to two women employed there. The bacillus was found in the noses of those women, who are now segregated and under medical care, though they have not developed the disease themselves.

Proposal for Sick Children's Hospital in Dundee.

The committee formed to make full inquiry into the whole question regarding a new sick children's hospital for Dundee have after consideration come to the conclusion that for the present the scheme is impracticable. Sufficient funds, in their opinion, would not be forthcoming, and the committee recommend that the directors of the infirmary be approached to see what accommodation can be provided at the infirmary.

Medical Service in Skye.

A deputation of the Highlands and Islands Medical Service Board visited Portree on April 23rd and had an interview with representatives from the seven parishes in Skye. Evidence was given on the financial positions of the Martin Hospital, Uig, and the Mackinnon Hospital, Broadford, it being stated that the latter is altogether dependent on outside aid. It was suggested that besides the fever hospital at Portree another is required to provide the necessary accommodation for the needs of the district and of the growing iron ore industry which is now established at Raasay. Nursing in the various districts was also discussed. Locomotion is very difficult, many of the roads being not passable for bicycles. Inquiry was also made into the housing accommodation available for doctors and nurses, and also into the need for providing a motor ambulance to be stationed at Portree, to be used for the conveyance of patients to the various hospitals.

April 28th.

IRELAND.

Irish Medical Association.

THE annual meeting of the Irish Medical Association has been arranged for Wednesday, June 3rd, and is to be held in Dublin. Dr. F. W. Kidd has accepted nomination for the presidency. He has had long experience in the working of the association, and he holds the full confidence of the profession.

Royal College of Physicians: Honorary Fellowship for Sir Arthur Chance.

On April 23rd Sir Arthur Chance, the well-known Dublin surgeon, was formally admitted to the honorary Fellowship of the Royal College of Physicians of Ireland. The ceremony took place in the College hall, Kildare-street, in the presence of a large assembly. The registrar of the College, Dr. Percy Fitzpatrick, introduced Sir Arthur Chance to the audience in a sympathetic speech, in which he made special allusion to the splendid work done by their new Fellow as a member of the General Medical Council. The President, Dr. C. E. Fitzgerald, then formally admitted Sir Arthur Chance to the Fellowship, afterwards investing him with the appropriate gown, and spoke in eloquent terms of the esteem and affection with which he is regarded by his colleagues.

The Friendly Societies and Certification.

At a meeting of the executive committee of the Orange and Protestant Friendly Society held on April 21st a resolution was passed recommending that for the purposes of certification whole-time doctors should be appointed to certify those incapable of work, always provided that a number of certificates be apportioned to each society, and that the society shall have the right of nominating candidates for such appointments.

Meath Hospital.

The annual meeting of the Meath Hospital and co. Dublin Infirmary was held recently in the hospital. The report stated that the debit balance against the hospital had increased during the year from £8509 7*s*. 5*d*. to £9211 14*s*. 1400 patients had been treated in the wards during the year and 8106 accident cases attended. The dispensary cases numbered 9924. The average number of beds occupied was 117·43. An appeal was made for funds to build a new operating theatre.

Poliomyelitis in County Tyrone.

At a meeting of Cookstown rural council held on April 25th four deaths from poliomyelitis were reported, three being members of one family and the fourth a cousin, all in the Stewartstown dispensary district. Three other cases are doing well. The houses, the church, and the school, where the children were present, have been disinfected. It was decided to remove all cases to the hospital.

April 28th.

PARIS.

A Hunger Strike in the Paris Asylums.

THE Conseil Général de la Seine, on Dec. 24th, voted that the hospital staffs should be allowed to get their evening meal away from the hospitals, authorising for this purpose a per capita allowance of 85 centimes. The object of this arrangement was to permit of married outside employees having one meal daily with their families. As, however, four months elapsed without any attempt being made to bring this ruling into force, and as the direction of the Assistance Publique, notwithstanding repeated requests by the members of the syndicate of hospital nurses, refused to state at what date they would give effect to the ruling, the syndicate, weary of waiting, decided on a hunger strike in the asylums of Vaucluse, Villejuif, Maison-Blanche, and St. Anne, and 900 male and female nurses accordingly refused their evening meal. Out of courtesy to the catering staff they informed them that their action was intended as a strike, and not in any sense as a mark of dissatisfaction with the culinary service. The strike lasted four days, after which the Assistance Publique agreed to fix a date at which the new regulation should come into force.

A Backward Step in the Crusade against Alcohol.

Notwithstanding the efforts of the medical profession to obtain from Parliament the regulations necessary to repress alcoholism, a regrettable backward step has been taken by the Chamber of Deputies. On the eve of a new election the Chamber has voted for the suppression of the wine-seller's licence—that is to say, of the permit required by law for opening a drinking shop, which entails the payment of an annual toll. Besides the fact that by the loss of this toll the Budget will lose 38 millions of francs yearly, no restraint is any longer placed on the establishment of new drinking shops. Bills for limiting the number of these places, by controlling the establishing of new ones, have been brought many times before Parliament, but as often rejected, though each time with a decreasing majority, so that a hope was entertained that such a Bill would one day pass. The profound dismay at the action now taken may therefore be understood. Unfortunately, on the eve of an election the deputies feel the need of securing at all costs the support of the publicans, whose premises for the most part serve as meeting places where the chances of future elections are discussed. Consequently, at the end of its term, every four years, the Chamber of Deputies rarely fails to commit some folly of this kind, or to accept some outrageous expenditure in favour of interested localities whereby the members hope to gain the support of the electors. The Bill, however, will not become law until accepted by the Senate, whose members, being nominated by a limited constituency and for nine years, are less dependent on the discussions of pot-house politicians; and it is hoped that it will reject this Bill, whose authors will by then have received the benefit of it in the shape of re-election, which for most of them is all that matters. Nevertheless, the Anti-Alcohol League has forwarded to the Senate an energetic protest, in which its president, Professor Debove, points out the dangers that would ensue should the Bill become law.

April 27th.

SOUTH AFRICA.

Sanitation at the Mines: Report of Surgeon-General Gorgas.

THE Transvaal Chamber of Mines has just issued the report of Surgeon-General W. C. Gorgas, late chief sanitary officer of the Isthmian Canal Commission. This officer, it will be remembered, was invited by the Chamber to investigate the causes of the high death-rate from pneumonia among the native labourers, and to make such recommendations as might appear necessary for the reduction of the mortality and the improvement of the general sanitary conditions of the mines and compounds. In his investigation, which began in December last, he was assisted by Major R. E. Noble and Dr. S. T. Darling, both on the staff of the Isthmian Canal Commission.

The report is an interesting one, and considering the short time at Surgeon-General Gorgas's disposal he was evidently able to make a fairly thorough survey of the conditions on the Rand. In the course of the report he points out that the uniformity with which pneumonia attacks preponderatingly the recently arrived native is as pronounced on the Rand as it is on the Isthmus of Panama, and that this seems to be the only generalisation yet drawn with regard to the incidence of pneumonia of epidemiological value. This indicates that the question of immunity is the most important element in the causation of the death-rate. In the construction of the Panama Canal in its incipiency there was much the same trouble with pneumonia amongst the negroes as amongst the natives in the mines of the Tranvaal, and the death-rate for pneumonia among the black employees of the Canal Commission in 1906 was 18·74 per 1000, higher than the death-rate for this disease among native employees in the proclaimed labour district of the Transvaal for any year since. During the first few years on the Isthmus the negroes were housed in barracks containing 84 men, and of such dimensions as to give them about 30 feet each of floor space. In 1907 the Commission allowed the negro labourers to scatter out along the line of the canal and to build huts and bring out their families. There was a sudden and permanent drop in the death-rate from pneumonia, due, in Surgeon-General Gorgas's opinion, mainly to the scattering of the natives, and he argues this step should if possible be taken on the Rand. He points out that the most serious sanitary defect on the Rand is the matter of housing.

Conditions of Housing.

The native quarters are much too crowded. The native labourer has generally about 200 cubic feet of air space, or about 14 feet of floor space; the occupants are thus in close personal contact. and the spread of any infectious disease is largely increased. This applies particularly to pneumonia, tuberculosis, and cerebro-spinal meningitis. The great American sanitarian thinks that if the native labourers were to be placed in individual buildings with their families it would have the same result as on the Isthmus. It reduced the death-rate from pneumonia there in the course of a year from 18·4 per 1000 to 2 per 1000. It would probably reduce the Transvaal rate of 15 per 1000 (the highest monthly rate for 1913) to 2 per 1000. If this is not considered feasible at present the nearest approximation to it should be attempted. What does strike him as feasible is to extend the family locations, and instead of spending large sums in recruiting endeavour to attract a permanent force of married men who would live in the locations and be always available as a source of labour for the mines. Such locations should be self-supporting, and would correct the unsatisfactory health conditions of the compounds by giving more floor space *per capita* to those who continue to live therein. If it is not possible to put the natives into huts with their families, he recommends that they should be put into huts without their families, arranged so as to give each native 50 square feet of floor space. If huts are not practicable, they should be put into barracks, but the latter should be divided into small rooms and arranged to give each native 50 square feet of floor space.

Surgeon-General Gorgas notes that the compounds appear to be well kept, but that in the native living quarters the very opposite is the case.

> Food was always present in dirty vessels in considerable quantities, old clothing and wearing apparel of all kinds, soiled and dirty, littering up everything, and litter of all kinds was stowed away under the sleeping platforms.

He does not think that much in the way of correction can be done in the present overcrowded condition of the barracks.

Immunisation.—Death-rates.

He considers that the question of immunisation for pneumonia as recommended by Sir Almroth Wright should be more carefully looked into, and he suggests that it would be useful for the experimental inoculation against pneumonia to be continued, using the different strains of pneumococci. When inoculating natives he considers that at least one-half at present should be kept as controls. He points out also that the death-rate from enteric fever is far too high, and expresses the opinion that it would be abolished altogether if all native employees were vaccinated for enteric fever as a routine procedure.

The report deals at length with the statistics showing the prevalence of pneumonia and other diseases amongst natives. The death-rate among natives employed on the mines and on industrial works in the Transvaal in 1903 was 71·7 per 1000; in 1912 for some 300,000 employees in the same area it was 26·84. "This rate," says the report, "is still very much too high, as we are considering men in the prime of life." According to the Native Affairs Department, the total death-rate in this year from diseases was 22·6 per 1000, the four highest being pneumonia 9·8, phthisis 5·4, meningitis 1·3, and enteric fever 1·1. It is pointed out that—

> these four diseases are all more or less infectious and contractable. If they could be gotten rid of entirely, the rate for 1912 would be reduced to 5·0 for all other diseases. While the eradication of these diseases cannot at present be accomplished in this or any other community, probably by proper hygienic measures a very appreciable reduction could be accomplished.

Summary of Recommendations.

In a summary of the recommendations, the report states:—

> Of the sanitary recommendations, I consider that of increasing the floor space to about 50 feet the most important and pressing, and by far the best way of doing this to be the village hut system and the introduction of families. If this particular method cannot be carried out, to come as near it as possible. The second in importance I consider the improvement in the hospital system and the care of the native sick. This can be best carried out by a central hospital. If a central hospital is not possible, by such concentration of hospitals as is possible. The third in importance is the establishment of a central sanitary bureau or department under the Chamber of Mines, the head of this department to represent the mines on all sanitary questions. The revision of the present regulations regarding matters of sanitation, so that the sanitation of the mines might be accomplished by the authority of one official of the Government or municipality, instead of with five different interested parties as is now the case.

In regard to these recommendations, it will be remembered that Sir George Turner, when medical officer of health for the Transvaal, on more than one occasion came into conflict with the mining houses on the ground that insufficient air space was provided for native labourers, and there can be little doubt but that it is high time that steps are taken to remedy the evil. On more than one occasion this question has been referred to in THE LANCET. It is very doubtful whether the village system could be greatly extended, and even if it were possible it is doubtful whether a permanent force of skilled workmen would be always available as a source of labour for the mines. Surgeon-General Gorgas has overlooked the fact that the average kaffir will not work for more than about six months in the year, and that considering the nature of his work on the mines it is perhaps as well that he does not do so. It will be generally agreed, however, that the strictures passed on the existing native quarters are fully justified, and that these buildings call for alteration with a view to remedying their overcrowded condition. Also no one will find reason to doubt the wisdom of the recommendations made in respect of the mine hospitals. The need for improvement here has long been felt. The staffing of these hospitals is also unsatisfactory, and it would be well if they could be staffed with coloured female nurses instead of orderlies. This, however, could not be done at once for lack of trained coloured nurses. With the recommendation for the centralisation of sanitary control under one authority no one can quarrel. This has already been urged in these columns. It is doubtful, however, whether the Chamber of Mines should directly have anything to do with it. What is required is a board of health representing the municipalities, the Chamber of Mines, the Department of Native Affairs, the Department of Mines, the Department of the Interior, and the Provincial Government. This board should be given special rating powers, and should control through a medical officer of health the sanitation of the whole area. Something of this sort is what Surgeon-General Gorgas probably means, but he does not say so definitely.

Surgeon-General Gorgas and his staff are to be congratulated on the work they have accomplished, and it is to be hoped that his recommendations will be given trial as far as practicable.

March 31st.

DONATIONS AND BEQUESTS.—By will the late Mr. Ernest Dresden, of London and Newmarket, left £5000 to the Middlesex Hospital and £1000 each to the Rous Memorial Hospital, Newmarket; the County Hospital, Bury St. Edmunds; the Infant Orphan Asylum, Wanstead; the Cancer Hospital, Fulham-road, S.W.; and the Hospital for Children, Great Ormond-street.—The late Mr. Frederick Burton, of Pendleton, Manchester, and Gwaynynog, Denbigh, has left £2000 to the Salford Royal Hospital and £1000 each to the Manchester Royal Infirmary and St. Mary's Hospitals, Manchester, and £500 to the Denbigh Infirmary.—Under the will of the late Mr. Henry Skeate White the testator left £200 each to the Royal Ear Hospital, Soho; the Royal Dental Hospital, Leicester-square; the Royal Hospital for Incurables, Putney; and the British Home and Hospital for Incurables, Streatham.—The late Mr. David Sturrock has left £1000 to the Glasgow Western Infirmary for the purpose of endowing a bed to be called the David Sturrock bed.—King Edward's Hospital Fund for London has received £500 from the Clothworkers' Company.—The late Dr. William Watts Thetford left by will £100 to the Royal Medical Benevolent Fund Society of Ireland.—Mr. L. E. Raphael has presented the Jewish board of guardians, of which he is a member, with a gift of £2500 for the purpose of providing sick children with treatment in hospitals or at the seaside.—The late Mr. Francis Arthur Farrell, of Dublin, has left £200 each to the Hospital for Incurables at Donnybrook, St. Mary's Asylum for the Female Blind, Dublin, the Mater Misericordiæ Hospital, St. Vincent's Hospital, and St. Michael's Hospital, Kingstown.

Correspondence.

"Audi alteram partem."

LUNACY IN EGYPT.

To the Editor of THE LANCET.

SIR,—A most interesting problem in the treatment of the insane is at present being worked out under very trying conditions in Egypt. About 20 years since a start was made by Dr. F. M. Sandwith at the disused palace of Abassia near Cairo. The palace was badly adapted for the reception of lunatics, but by degrees it has been brought into shape, fresh buildings have been added, and quarters for the medical staff have been built, but every visit to the place impresses the visitor with the great difficulties, structural, economic, and administrative, which have had to be overcome. The governing authorities looked upon the whole matter as a nuisance, because there were constant calls for money for work which they considered unremunerative. There was at that time no real lunacy department, the asylums being under the Department of Public Health. Much was attempted and a great deal done by Dr. J. Warnock, who for 18 years has been struggling against enormous odds. It is wonderful what he has managed to do. The method of the working of the large and crowded asylum is splendid, and to this I shall refer later. His work now stands a good chance of recognition and, what is more to him, of receiving genuine support. On April 1st the then head of Public Health in Egypt handed over the asylum work to the Ministry of the Interior. Dr. Warnock continues to be the head of Abassia, and will also be Director in Lunacy for Egypt. It is anticipated that some definite sums of money will be specially provided for the regular development of the care and treatment of the insane.

The overcrowding and overwork have caused delay in producing the annual reports, so that the reports for the years 1911 and 1912 have only just been received. During that time the chief matter of importance has been the starting of what one may call the relief asylum at Khanka, on the other side of Cairo. This is only begun, but in due course will develop into a very large asylum. Another matter of general importance is that the criminal lunatics have been removed from Tura to Abassia. This involves extra work and extra risks to the officers and staff, and I cannot help thinking this can only be a temporary measure, for the English experience is that criminal lunatics should be separated from the non-criminal ones.

The great difficulty of obtaining trustworthy nurses, male and female, is felt. The lack of Egyptian women who are in any way trained or trainable makes it imperative that the backbone should be trained English nurses. This deficiency, after years of effort on the part of Dr. Warnock, has been partly met this year by three English asylum nurses being obtained. As is pointed out, too, the pay at present for the men is not sufficient to attract those who are suitable. When it is shown that the majority of the nurses can neither read nor write, nor in fact recognise the numbers of the doors of the bedrooms, it will be seen how grave is the task of working with such material.

Special attention is called first to the overcrowding of both the parent and the second, or relief, asylum. Many patients have to sleep on the ground, though this certainly is not felt to be a hardship by the natives. Next, as a result of the crowding, patients have to be discharged as soon as they cease to be actively dangerous. One consequence of this has been that a certain number of these unstable persons have committed crimes, and it has been said that the Abassia patients have contributed to the serious crimes in Cairo; but Dr. Warnock shows that this is not true, and that criminals have found it convenient to plead past or recent lunacy and thus have hoped to escape their full punishment. Doubtless some of the convalescent patients have committed crimes, and as so many of the patients admitted have been suffering from abuse of alcohol or hashish, it is not surprising that on their release they return to the habit and again become dangerous.

Another point of interest is the very large number of recent injuries from which the residents in the asylum suffer. The numbers would astonish the English Commissioners. They are partly to be attributed to the untrained attendants and partly to the infusion of criminal lunatics and the hashish maniacs. The number of sufferers from pellagra is noteworthy, and Dr. Warnock contributes interesting pathological observations on the post-mortem changes which he found. He is certainly convinced that maize is not the one and only cause of the disease.

The reports give in most elaborate detail all the facts and statistics which can be wanted, and must have involved an enormous amount of work. Tables are given showing the admissions and discharges, the forms of malady, duration of disorder, the causes of the disease, and the cost of maintenance, with all the details of the costs of administration. One can only admire the clear and definite way in which every part is explained.

One, therefore, feels now that there is a fair prospect before the Director of Lunacy that this work, so well started and developed, will be continued under his direction until the whole of lunacy can be treated along fixed and definite lines. The two asylums are not enough, for though the relief one at Khanka will in time receive 1000 patients, yet that will not suffice for all Egypt. In the report it is shown that many insane pass through the various general local hospitals, but the medical officers at these institutions have as a rule a very limited experience of insanity, and are not competent to treat or even advise as to the need of asylum treatment for the cases which are sent to them. It is certain that there ought to be a well-established criminal lunatic asylum not far from Cairo, and probably some hospital asylum for the paying cases and for Europeans. There is no fully recognised system of lunacy law in Egypt, and for this there is special need of the practical experience of Dr. Warnock.

Before concluding this letter on Egyptian lunacy one must make a special reference to the asylum at Khanka, under Dr. H. W. Dudgeon, who has had over ten years' experience in Egypt. A large farm has been taken, and it is determined to try to work this farm by quiet and harmless patients so that it shall produce the vegetables for both asylums, and later possibly produce profitable crops such as cotton. The space is ample. The general want being water, it is hoped that soon communication will be established by the Irrigation Department with a canal near, thus giving a more regular supply at all seasons. At Khanka the difficulty of overcrowding exists, for with ample space the buildings are still wanting. The administration is difficult, for though they receive the quiet cases, yet as soon as these become useful workers the pressure of space requires that they should be discharged, though it would be better for their future if they could remain longer under care. The isolation of Khanka is a trial for the resident officers and their families which makes prolonged holidays necessary.

I must conclude by expressing satisfaction at the work done and the prospect of its further encouragement by the Government.

I am, Sir, yours faithfully,

Devonshire-place, W, April 21st, 1914. G. H. Savage.

THE UNIVERSITY OF LONDON AND EXTERNAL DEGREES IN MEDICINE.

To the Editor of The Lancet.

Sir,—Your editorial note to Dr. A. Percy Allan's letter in The Lancet of April 18th challenges a reply which has been delayed owing to my absence from town. In that note you reaffirm the correctness of a statement made in your leader of March 21st which had been so definite that I had concluded that you had received information not at my disposal; but the sole authority which you give for the statement is the report of the Commission, and I submit with all courtesy that you have misread the latter.

The statement to which I refer reads thus in your leader of March 21st: "...... the spokesmen from all the London medical schools but one, and a number of other witnesses, urged the abolition of the external degrees in medicine." The reference in the report, which you give as your authority in your editorial note, runs thus: "Moreover, with the exception of the witnesses from St. ...... Hospital Medical School, all the witnesses from the London medical schools, *who referred to this matter*, and a number of other witnesses, urged the abolition of the external degree in medicine."

I submit that the omission of the qualifying clause, which I have italicised, makes your version much more sweeping than that of the report; and that it is not supported by the facts is evident from an inspection of the footnote to the reference, in which the schools which are instanced as having given hostile evidence are specified by name. Omitted from this list are not one but four schools, whose importance may be measured by the fact that they contribute 547 University students as against the 454 such students contributed by schools which are included in that list. Dr. Allan will be pleased to know that "Guy's" is not named with the hostile schools; in fact, the representatives of Guy's made it clear that there was a majority at their school in favour of the retention of external degrees, but this is not mentioned in the report of the Commissioners, who are anxious to draw attention only to the opinions of critics hostile to the external side. Indeed, they are apparently not above twisting expressions of hostility out of evidence which does not sustain that imputation, as in an instance I give immediately below.

The "other witnesses" referred to both by the report and your leader are also specified by name in a succeeding footnote in the report. As so much has been made of these it is of some importance to analyse this list in turn. There are seven names cited. The first is Lord Moulton. A perusal of his evidence, which in its general tenour is an impressive appeal for continuance of external degrees, shows that the only countenance for including him in a list of "witnesses who urged the abolition of external degrees in medicine" is to be found in his admission that "tuition and residence" are necessary in the case of medical students who cannot qualify by "private study." But he nowhere says that the tuition and residence must be restricted to London schools.

I have before me as I write a letter from Lord Moulton, dated April 20th, 1914, in which he says: "I remember nothing that I said in my evidence before the Commission which could justify the use of my name as supporting the abolition of the external degree in medicine." I submit, therefore, that Lord Moulton is quite improperly included in this list, and I have his authority for publishing the categorical denial quoted above. Of the remaining six witnesses, five are Professors or Fellows of University College. This is surely a noteworthy preponderance, and inevitably leads to the inquiry whether this college has any material interest in the suppression of the external degrees in the University, an interest which would make this collective hostility of its members a mere act of laudable patriotism towards their college, but which would at the same time necessarily detract from its moral force as a protest against those degrees. There is abundant evidence for answering that inquiry in the affirmative.

"It is openly avowed," says Dr. Waller (himself a purely internal representative on the Senate), "on the internal or College side that the existence of the external side of the University of London is an intolerable hindrance to their development. To the disinterested spectator the position of the Colleges now incorporated in the University of London of 1898 has been one of steady progress towards the acquisition of an unimpeded monopoly. ...... During the last ten years the Colleges have become incorporated by the University, and have steadily drawn the clothes over to their side of the bed and steadily complained of the intolerable pretensions of their external bedfellow. In this respect we may certainly admit that the policy of University College has been a continuous and unchanging policy."[1]

I claim to have shown that the extent of the opposition to the retention of the external degree in Medicine has been greatly exaggerated, and, further, that where it exists it is very largely an interested opposition. May I, in concluding, compliment you on the generosity of your reception of my letters, a generosity which has, indeed, justified your proud motto of "Audi alteram partem."

I am, Sir, yours faithfully,

Wimpole-street, W., April 27th, 1914. E. Graham Little.

THE EFFECT OF THE INSURANCE ACT ON NATIONAL NUTRITION.

To the Editor of The Lancet.

Sir,—May I put in a plea for a more careful consideration of the economic effects of the Act than it generally obtains in the medical press? It is often forgotten that the problem of the public health is mainly economic. If the poor were well-to-do their death and sickness rates would rapidly fall to the level of those of the classes above them; and the question that confronts a statesman is not to deal with disease, leaving poverty unrelieved, but to do all he can to abolish poverty in the sure knowledge that the rest will follow of itself.

---

[1] A Short Account of the Origins of the University of London. By Augustus D. Waller, F.R.S., LL.D., Member of the Senate, late Dean of the Faculty of Science in the University of London. (See p. 22.)

Free trade rapidly gave to England the lowest death-rate of any industrial or populous country in the world, and the lesson it teaches is that if you would make a people healthy you must raise real wages (i.e., make necessaries plentiful) by freeing production; and that the distribution of these necessaries may be left to natural agencies. It follows, in accordance with Dr. Farr's well-known maxims, that if a malignant government aimed at lowering the health of the community its readiest method would be to tax production.

Apart from the degradation of compulsion applied to a class because it is poor, the blot on the Act is the 5*d.* weekly per head said to be given "free" to the beneficiaries. The older economists knew and preached that the State cannot make a gift to the working class save at the expense of the normal market rate of (real) wages. Every business man takes into consideration all the expenses of his trade, and bases his prices on those expenses, whether normal or imposed by State or municipality, where he can; and it is only the struggling businesses which cannot in the long run recoup themselves for rates and taxes. In a word, a business man gets interest on his outlay, and his outlay includes artificial State burdens. This fact has been proved *ad nauseam*, and the child-like faith that a Ministry has only to say that the employer must pay a tax to prevent him transferring that tax would seem difficult even for legislators intoxicated with the sense of their omnipotence, when they see, as they must see, that the gross assessments to income-tax have risen faster under a Government which has set itself to tax the rich, than under the Government which conducted the Boer war; while they have at the same time to admit that wages have fallen in purchasing power, and specially—as Mr. Ramsay Macdonald himself has just stated—in the last two years. In a word their efforts have made the "rich richer and the poor poorer."

A very simple test may be applied to the Act—Would it have been passed if the beneficiary had been made directly responsible for the whole 9*d.*? It is safe to say that not only would it have not been passed, it would not have been suggested. But the case is worse, if under the pretence of a partly free benefit, Government has actually put more than the whole burden on people whom they state to be too poor to afford the uncomplicated cost. No one can go from cottage to cottage and hear the constant complaint of raised prices (in which the Act plays a dominant part) without seeing that the Insurance Act has already done that; the day I wrote this, a workman's wife estimated that she was paying "something like 2s. for the 9*d.*"; that is, no doubt, a great exaggeration, but there is no question that the cost of the 9*d.* will go on rising for some time. For the well-to-do among the working class this diminution in real wages does not matter much; but no one pretends that the Act was necessary for these, who were all well insured before. To the class for whose benefit it was intended, the class which must save any possible extra expense out of food, this means dire distress in times of depressed trade; and, looking at their case, one is driven to believe that the Act is a dreadful mistake. To relieve some it has made all poorer. No administrative benefit can ever compensate for lowered nutrition. Without Mr. Masterman's promises at the Bethnal Green election we knew that sooner or later the benefit for this class will have to be free, and if for one section, necessarily, as in the case of education, for all sections. Friends of the Act who trust that by sheer weight of organisation it must endure are living in a fool's paradise. English people have never yet been forced into a duty, for the performance of which they must directly pay; in this single instance of education of their children (which yet stands on a different footing) they have had to be deluded into the notion that they do not pay. If this Act becomes wholly "free," it has become a poor law, naked and unashamed, and falling with all its cruel, if unappreciated, weight on the very class it is meant to relieve. The alternative is that right English remedy, the voluntary system. If you must advocate compulsion, there is a third way, the honest and the cheapest way, which, like the voluntary system, would have the merit of raising wages—viz., putting the whole cost directly on the beneficiaries. But as no Government dare suggest this, it is out of the range of practical politics.

I am constantly meeting with working men who already suspect that they are bearing, now before two years are past, more than the whole cost; if the conviction becomes general there is no fear that the Act will endure on its present basis; and the solution which will naturally suggest itself is voluntaryism. The dilemma in which the profession finds itself is highly unpleasant. Either we are gaining by the Act, in which case we are parasites on the community, guilty of that worst of national sins, depressing the level of wages; or if we are losing, as many of us are, we are being despoiled by the State which should protect us in all legitimate enterprise, in compensation for our clear conscience. But at least we can do this, and I suggest it as a duty for all men, whether advocates of the Act or haters of it with a hatred that grows from day to day; we can do our utmost to stimulate clear thinking among panel patients, and to induce them to inquire whether they are really getting benefits at the ostensible rate or buying them at a cost that spells disaster to the poorer among their ranks.

I am, Sir, yours faithfully,

B. G. M. BASKETT, M.B. Oxon.

Rayleigh, Essex, April 21st, 1914.

THE PAYMENT OF FEMALE MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—You were good enough to publish a letter under this heading *re* salaries under the Board of Control (Mental Deficiency Act) in your issue of Feb. 28th from Dr. F. M. Dickinson Berry and myself. As a result of that letter Dr. Sophia B. Jackson, who was an accepted candidate for the women's post of medical inspector under the Board of Control, and whose self-sacrificing stand for the principle of equal pay for equal work in the medical profession is well known, on being interviewed by the Board, made her acceptance of the post conditional on either the salary being made equal to that of the medical man doing the same work or the work to be done being definitely restricted. The second candidate also made the same stipulations.

A good deal of correspondence between the first and second candidates, the Board of Control, the British Medical Association, and the Registered Medical Women's Association has taken place, and briefly summarised is as follows. On April 8th the second candidate wrote in thorough concurrence with Dr. Jackson's *actions, stating that* she would certainly decline to accept the post were it offered to her. On April 9th Dr. Jackson was informed *that* the second candidate had had a conversation with one of the Commissioners of the Board of Control, who told her the work was restricted, and that the post would probably be lost to medical women if the stand of equal pay were forced, because the salary had been fixed by the Treasury and was unalterable. At the same time she gave Dr. Jackson to understand that if she (Dr. Jackson) persisted in refusing it, she (the second candidate) would feel justified in accepting it. She also added that she would take no "definite step" till she had communicated with Dr. Jackson. The second candidate eventually accepted the post.

Within the last few days an official letter has been received stating that the Board have come to no decision, as alleged, that the duties of the woman inspector to be appointed under the Board *are to be "definitely restricted."*

In these circumstances, surely any candidate who had accepted a post, believing certain conditions were attached to it which now she knows are not, should refuse to take it. I pass by the extraordinary fact that a Commissioner should make statements that are proved to be incorrect, on the strength of which we may assume the candidate accepted the post.

Apologising for the length of this letter, which I am sure you will allow to deal with principles vital to our profession,

I am, Sir, yours faithfully,
JANE H. WALKER,
President of the Registered Medical Women's Association.

Harley-street, W., April 28th, 1914.

THE BIOLOGY OF TUMOURS.

To the Editor of THE LANCET.

SIR,—The difficulty of defining the relationship that exists between growth and reproduction (growth beyond the individual) to which Mr. H. C. Ross refers in THE LANCET of April 25th, is very largely due, it appears to me, to his assumption that such a highly specialised structure as a cell is to be taken as the unit of life. It is necessary to go much farther back—to what we believe to have been the simplest and most primitive beings, to the time when life made its first appearance upon the earth. Whatever the relationship that existed between growth and reproduction then, it is the same now. Details may have changed, but not the principle.

In these primitive forms of life reproduction was the direct outcome of continued growth. Bulk increased by the ingestion and assimilation of foreign matter until the size of the organism was no longer suited to its environment and it was forced to divide. The dimensions varied in each case. There was no definite size at which division took place. It depended entirely upon circumstances, but when circumstances continued to be the same for generation after generation it gradually came about that division (reproduction) occurred at more or less regular intervals. Then two classes of organisms arose—one in which the daughter units separated from each other at once and lived apart; the other in which they still maintained their connexion with each other. But the power of division (reproduction) remained the common property of every unit in equal degree. The former class advanced no farther. They are the protozoa still. In the latter, owing to emergencies imposed by the division of labour, the function of reproduction which had been the common property of every unit gradually became restricted to one special group of cells. In these the power was developed more and more highly as time went on, and it diminished proportionately in all the rest. But it did not disappear or die out. With the exception of very highly specialised structures, such as the organs of special sense, the power of reproduction is still present in all tissues and can be called into action at any moment, especially while the cells are young.

Reproduction, therefore, is only a form of growth. External conditions originally determined when the growth of the individual should become growth beyond the individual; and these conditions, acting from immeasurable time, impressing their power upon generation after generation, at length led to reproduction taking place only when a definite stage of growth was reached. Auxetics may stimulate reproduction, but reproduction is the product of hereditary transmission from the time when life began upon the earth.

Mr. Ross asks me to suggest a line of experiment. There are certain clinical facts which seem to me to point with no uncertain finger. The secret of the origin of tumours (including cancer) lies not in trying to find influences or agents that will stimulate growth and reproduction, but in isolating and investigating the action of substances that possess the power of checking development and interfering with functional activity. Development controls growth and reproduction. If development is arrested (as, for example, the development of epithelial cells is arrested under certain conditions by arsenic or soot) the functional activity of the tissues is arrested; the power of growth and reproduction, or so much of it as the cells still retain, is freed from control, and if there is the least provocation, such as may be caused by continued irritation, cells and tissues at once begin to increase and multiply at their own free will. The result is a shapeless, formless mass of cells, resembling more or less closely the parent that gave them birth, never advancing beyond it in development, never doing any useful work, but growing without ceasing, so long as there are supplies of food—in other words, a tumour.

I am, Sir, yours faithfully,
C. MANSELL MOULLIN.

Wimpole-street, W., April 27th, 1914.

WILLIAM HAWES AND THE ROYAL HUMANE SOCIETY.

To the Editor of THE LANCET.

SIR,—Your interesting annotation on this subject in THE LANCET of April 25th rekindles the embers of a controversy which a century and a half ago was waged with characteristic mid-Georgian scurrility on either side. Hawes, as you say, published in 1774 "An Account of the Late Dr. Goldsmith's illness so far as relates to the Exhibition of Dr. James's Powders, &c." This pamphlet, with subsequent corrections and the accretion of an appendix, ran through several editions in the course of the year. Perusal of it leaves one in doubt as to whether Goldsmith died in spite of James's powders or because of them. I would add that a leading argument of the pamphlet is based on Hawes's own statement that he was not a doctor, but an apothecary, so that I am not sure that he should be entitled "Dr." Hawes. But the claim put forward by Hawes to be the pioneer in establishing the Humane Society was too much for his brother apothecary F. Spilsbury to swallow in silence, and in 1776 he published a venomous tract entitled "Free Thoughts on Quacks and their Medicines," full of personal abuse of Hawes. In this tract Spilsbury asserts that all the directions for establishing such an institution had long since been laid down by Dr. Mead in an essay "Of the Mad Dog"; but what is more to our point, he proceeds to show that Dr. Alexander Johnson was "really the first promoter of the scheme for establishing in this kingdom an institution for the recovery of drowned persons, after the manner of similar institutions, already established in France, Holland, Germany, and other places," which had greatly impressed him during his travels abroad. Of his priority to Hawes, at any rate in the matter of publication, there is no question, for in 1773 Johnson had published in London "A Short Account of a Society at Amsterdam Instituted in the Year 1767 for the Recovery of Drowned Persons, with Observations Showing the Utility and Advantage that would accrue to Great Britain from a similar Institution Extended to Cases of Suffocation by Damps in Mines, Choaking, Strangling, Stifling, and other Accidents, by Alexander Johnson, M.D." Now, if this were all, we might well assume that Hawes was unaware of Johnson's work, and had inadvertently and independently turned the same furrow; but it is not all. In the Annual Register, Vol. XX., 1777, Hawes is to the fore again with a project, which he entitles "Cautions against the Burial of Persons Supposed Dead." After some blood-curdling assurances of the frequency of burial of the living he proceeds: "It was the intention of the writer to publish a work upon this subject, but as his various avocations will not permit him to carry that design into execution, he thought it his duty to throw out the above hints; and if they should be the means of preventing one person from being laid out, or, what is more horrible, buried alive, it will afford the writer a pleasure of the noblest kind, that arising from the consciousness of doing good to his fellow-creatures." Now there is hardly a single idea or illustration in this effusion by Hawes but which is transferred in crude and wholesale fashion from Johnson's publication, and this in spite of the fact that only a year previously Spilsbury had openly accused him of pillaging Johnson's wares. By all means let Hawes wear the halo you have so generously bestowed on him—may we all earn ours as easily!—but let us remember that the light that illumines it is but the reflected light of Dr. Alexander Johnson, doctor of physic.

I am, Sir, yours faithfully,

April 28th, 1914. RAYMOND CRAWFURD, M.D., F.R.C.P.

CASE OF SIMULATED GANGRENE OF THE LUNG.

To the Editor of THE LANCET.

SIR,—Some years ago in distant Vancouver I received an urgent summons to a patient I had occasionally but not recently treated for chronic bronchitis. On entering his room a putrid odour was noticeable, which I found came from a small quantity of expectorated sputum. The patient was pale, with pinched, drawn features, clammy cold surface, and small weak pulse, apparently *in extremis*. So much did he feel that way that he had sent for his lawyer to make an alteration in his will.

I did not doubt but that I had a case of gangrene of the lungs to deal with. As the first indication was obviously to rid the bronchi of the literally putrid sputum, I gave a full dose of vin. ipecac., which was the means of promptly bringing away more stinking sputum. In a few minutes there was a marked improvement in the patient's condition, and in less than 15 minutes he was out of danger. The next forenoon he was as well as usual. The presence of the putrid sputum and its resultant infection of the system was, there can be little doubt, due to the patient taking too freely of a patent sedative cough "cure," which caused the sputum—infected doubtless by some one or more of the flora which Dr. H. Batty Shaw in his lecture published in THE LANCET of April 18th enumerates as the cause of gangrene of the lung—to be retained. I had the patient under observation for some years after this experience and never knew of his expectorating offensive sputum again; the bronchitis somewhat lessened and the health improved. Had the patient died I would unhesitatingly have assigned gangrene of the lungs as the cause of death, and had a necropsy been made the neighbouring lung tissue would infallibly by then have become infected, and hence my diagnosis have been triumphantly confirmed. To my mind this single case shows that offensive expectoration, due to whatever cause, should be treated by frequent emesis.

I am, Sir, yours faithfully,

D. L. BECKINGSALE, M.D.Edin.

Hampden Club, N.W., April 21st, 1914.

EXTRAPERITONEAL URETERO-LITHOTOMY THROUGH A MEDIAN SUPRAPUBIC INCISION.

To the Editor of THE LANCET.

SIR,—I have read with considerable interest in THE LANCET of April 25th the article by Dr. Gordon Whitehead and Mr. John Morley on the method of approach of the lower end of the ureter by means of a median suprapubic incision.

During the last two years I have used in three cases a method which is slightly modified in that a vertical incision is used a little to one side of the mid-line, and I can fully endorse their statements as to its value in cases where a stone is impacted close to the bladder. I had believed that this method was a device of my own, but in the last (the March) number of the *Annals of Surgery* Judd has described three cases in which he used a similar method. In two of his cases, as in all of mine, the operation was deliberately planned as an approach to the ureter itself and the bladder was not opened. In one of Judd's cases, as in that reported by Mr. Morley and Dr. Whitehead, the bladder was opened previous to the laying bare of the ureter. The following is a brief account of the cases in which I made use of this method.

1. A male aged 35 years. Dull aching pain for 14 years in right loin, steadily increasing, and for two years definite attacks of colic. Never any trouble with micturition or hæmaturia. Neither kidney could be felt and nothing abnormal was seen in the radiograph. No abnormality of the urine. On cystoscopy indigo carmine seen to be secreted from left ureter; none from right ureter. Catheter passed readily up left ureter, but stopped abruptly three-quarters of an inch from opening of right ureter. A vertical incision 1 inch to the right of the mid-line was used, the peritoneum stripped off the bladder, and the bladder pulled over to the left. The bifurcation of the

common iliac artery was readily laid bare. After some difficulty the ureter was found; it was the size of a coil of small intestine, and hence was overlooked several times in the search. It was then easily traced to the base of the bladder, the vas being seen as it crossed and hooked on one side. The ureter was opened and a stricture found at its entry into the bladder. The catheter passed upwards, however, for a distance of 20 inches. It was evident that the pelvis was much dilated. The ureter was therefore ligatured and divided close to the bladder, the upper end of the ureter being freed as far as possible in an upward direction. The wound was then closed and the kidney, which was in a condition of extreme hydronephrosis, removed together with the ureter by the ordinary incision in the loin.

2. A male aged 30 years. Six weeks before admission sudden onset of acute pain passing from right groin to loin, followed by hæmaturia and frequency; one similar attack since. A radiograph showed an oval calculus in the position of the lower inch of the right ureter. On attempting to catheterise the right ureter the catheter was stopped 1 inch above the orifice. A 2-inch suprapubic incision was made 1 inch to the right of the mid-line. The ureter was readily found and traced down to the bladder, the stone being felt about half an inch above the bladder wall. The ureter was opened and the stone was easily extracted, a ureteric catheter then passing freely into the bladder. The opening in the ureter was stitched with three catgut sutures and a small tube inserted; the rest of the wound being closed. There was a slight discharge of urine for four days, after which the wound closed entirely, and the patient was discharged cured.

3. A male aged 42. Typical attack of renal colic two weeks before admission to hospital, followed by hæmaturia. The radiograph showed a typical shadow of a renal calculus about 2 inches above the vesical orifice on the left side. A catheter was obstructed at the corresponding point. An incision similar to that used in the last case was made to the left of the mid-line, and the stone easily extracted. There was a slight discharge of urine for nearly a week, after which the wound healed rapidly.

By the use of the lower rectus incision a very good view is obtained of the lower 6 inches of the ureter. Its point of entry into the bladder is laid bare and is rendered so accessible that operations upon it can be readily carried out, and the adjacent portions of the bladder are also exposed. The vas and vesiculæ can be seen, as also the iliac arteries. The peritoneum being unopened no difficulty is experienced from the proximity of the intestines. The operation being wholly extraperitoneal the danger of infection is slight and the wound can be freely drained. The exposure is infinitely preferable to that given by a parasacral or iliac routes.

I am, Sir, yours faithfully,
ALBERT J. WALTON.

Weymouth-street, W., April 25th, 1914.

THE FATALITY OF MEASLES.

To the Editor of THE LANCET.

SIR,—In a leading article in THE LANCET of Feb. 21st on "The Control of Measles" you quote with approval Dr. James Kerr's statement that "the chief hope of combating measles lies in improvements in regard to habits of life, housing, and space to live." No doubt this contains much truth, but it does not quite hit the principal nail on the head.

It is universally admitted that the fatality of measles is almost negligible among the educated and well-to-do classes, but considerable among the poor and ignorant. To a certain extent want of abundant fresh air and of comfortable accommodation is responsible; but the chief cause, I have long been certain, is the scare of a "chill" on the part of the poor and ignorant parents and friends; and in order to escape from this illusory Scylla they run into the real Charybdis of the opposite extreme. Thus the child is packed more or less tightly in a bundle of clothes—usually of flannel or flannelette—covered with a superabundance of impervious bedclothes, and sometimes (as I have seen in London) kept near a large fire, and, of course, in a badly ventilated room. To touch the skin with water would be looked upon as next door to murder, so that the child is not refreshed by washing or changing the clothes.

This process of overheating is, I believe, far more prejudicial and dangerous than any chill that is likely to be sustained while the pyrexial period lasts. It intensifies the disease, and it is the intensity of the disease that mainly determines aggravation of bronchitis or the onset of pneumonia—the chief causes of death. That this fact is recognised and acted upon by most medical men I readily allow, but I do not remember having seen it expressly stated, especially in codes of instruction for popular use.

Small-pox used to be regarded and treated in the same way by popular and medical assent until Sydenham taught the beneficial effects of keeping the patient cool and giving him fresh air.

It is, of course, useless, to expect any advantage from notification of the disease—the nostrum of many health authorities. The important desideratum is that cases of measles shall be attended by sensible medical men. If pneumonia should develop in the course of the disease, the most effectual treatment is blood-letting—not necessarily venesection as was always practised with good effect in old times, but, in the case of children, by the application of one or two leeches, which usually suffice.—I am, Sir, yours faithfully,

F. LUCAS BENHAM, M.D., M.R.C.P.

Exeter, South Australia, March 25th, 1914.

TRAUMATIC DISLOCATION OF THE HIP-JOINT.

To the Editor of THE LANCET.

SIR,—By an odd coincidence I read Mr. Harold Rischbieth's account of the above injury in a boy aged 10, reported in THE LANCET of April 18th, a few hours after seeing a boy who was in the Children's Hospital at Shadwell at the age of 7 for a similar accident. I had written to the boy asking him to come up to report himself.

On referring to my notes I find that the boy was admitted on Oct. 23rd, 1910. He had fallen down in the street on the day of admission and the left femur had been dislocated dorsally. He had suffered from no previous injury to the limb. The femur was markedly flexed, adducted, and rotated inwards, the left knee being in apposition with the lower end of the right thigh just above the right knee. The great trochanter was well above Nélaton's line, and there was a deep pit in Scarpa's triangle. Passive movements caused great pain. The boy was given chloroform and placed on a mattress on the floor. Reduction of the dislocation by flexion, adduction, and external rotation, associated with raising of the limb and sudden extension, was accomplished without great difficulty. A long side-splint was applied for 24 hours, after which sand-bags were substituted. Passive movements were commenced three days after the injury, and the boy was allowed to walk on Nov. 3rd. X rays showed no injury to bone or epiphysis. The history since the accident has been uneventful.

I am, Sir, yours faithfully,
HILDRED B. CARLILL.
Harley-street, W., April 24th, 1914.

THE STATE, THE MOTHER, AND THE CHILD.

To the Editor of THE LANCET.

SIR,—The leading article with this title in THE LANCET of April 25th approves "the efforts which are now being made to extend State action in all that relates to maternity and infant welfare," and says that "individualists, if any such remain," and "the eugenist," may argue against these efforts. Then you remark that "such arguments, however, usually appear to be pleas for inaction." This is very true; for few individualists and eugenists have the courage to advocate the extension of the knowledge of family limitation to the poor, which is the only alternative to State action on their behalf. So we are progressing towards a stage when the married couples with more than 30s. a week will be having an average of only one child per family in order to help to maintain the large families of those with less than 30s. a week! I earnestly hope, however, that there are many colleagues who share my view that if people were encouraged to have no more than one child for every 20s. or so a week poverty would soon cease to exist; the race would quickly improve, and a welcome freedom from meddlesome and costly legislation and officialism would ensue.—I am, Sir, yours faithfully,

BINNIE DUNLOP, M.B., Ch.B.
Alexandra Court, S.W., April 25th, 1914.

THE NATIONAL INSURANCE ACT.

LONDON INSURANCE COMMITTEE AND THE SURPLUS FUNDS.

THE London Insurance Committee by a majority of four votes has decided to draw up a scheme for the distribution among the medical men on the panel of the surplus funds arising in respect of unallotted patients. At a meeting of the Committee held to consider the matter, Mr. Kingsley Wood first moved that having regard to the opinion of Mr. Danckwerts, K.C., whose death is recorded this week, the Committee should inform the Commissioners that it could not proceed with the distribution. Mr. Kingsley Wood argued that there should be either judicial or Parliamentary authority before dealing with the fund, but he pointed out that no action had been instituted by the medical practitioners which would have facilitated the obtaining of a judicial decision. Mrs. Handel Booth moved an amendment to the effect that a scheme for the distribution of the money should be prepared and submitted to the Commissioners, who would have the opinion referred to before them and whose decision would absolve the committee. After discussion this amendment was carried by 27 votes to 23. With regard to the risks suggested in the opinion of Mr. Danckwerts, it may be pointed out that even though a distribution were to take place which in law were wrong, it might still be difficult to find anyone having such an alternative interest in the money as would entitle him to raise any question in the courts with regard to it.

SANATORIUM BENEFIT IN LONDON.

The London Sanatorium Benefit Subcommittee in a report on arrangements for the present year estimates the income to be dealt with at £100,000, and the required expenditure to include £40,000 to medical practitioners for domiciliary treatment, £7620 for drugs, £5000 for dispensary treatment, and £54,600 to cover the cost of 700 beds for institutional treatment. In an explanatory memorandum the Sanatorium Benefit Subcommittee quoted the Chancellor of the Exchequer as having stated that at first the payment of 6*d.* for domiciliary treatment might be very much too high. At present the amount of the payment under this head could not be varied, but the subcommittee noted that before the end of 1915 there would be a reconsideration of the whole position. If it were not for money accumulated during the first six months' working of the Act, when applications for sanatorium benefit were few, there would be a deficit of £10,000 this year in respect of institutional treatment.

LONDON PRACTITIONER VINDICATED.

The Medical Service Subcommittee communicated to the London Insurance Committee on April 23rd the results of its inquiries into a case in which a practitioner on the panel had been censured (in his absence) by a coroner's jury, it being suggested that he did not properly examine a patient. Treatment had been given for dyspepsia and rheumatism; the post-mortem examination showed advanced tuberculous disease. A curious feature of the case appeared to be the reticence of the patient as to his symptoms. He never mentioned that he had night sweats, and definitely denied that he had cough or expectoration; he only mentioned diarrhœa, stomachic pains, and rheumatic pains in the knee. The practitioner had examined the patient a year earlier and had found him to be organically sound. The medical members of the subcommittee advised that there was no evidence to show that the tuberculous disease of the lungs was in any way active at the time of death, or that it was an active agent in causing death. The conclusion arrived at was that the practitioner exercised proper professional care and was not negligent in any way. At the request of the practioner—Dr. D. J. F. Bennett, of Walworth, S.E.—his name was publicly announced.

ARBITRATION UNDER THE INSURANCE ACT.

The Scottish Insurance Commissioners were recently invited for the first time to arbitrate between an insured patient and an Approved Society on the question of the refusal of the latter to pay sickness benefit. The applicant was Mrs. M'Cartney, a member of the Scottish Catholic Society, which had refused her the benefit claimed on the ground that she was not incapacitated. Mrs. M'Cartney, in accordance with the rules of the society, applied to the Commissioners to appoint an arbitrator to decide the question, and Mr. R. D. M'Ewen, chairman of the Glasgow Insurance Committee, being duly appointed by the Commissioners, held an inquiry and found in her favour. The society appealed to the Commissioners against this decision, and the Commissioners have now issued their award upholding that of the arbitrator, and finding that the insured person was incapacitated for the period for which she claimed. The Commissioners further found the society liable for £3 3s. as costs. Congratulations are due to the medical man on the panel whose certificate has thus been upheld.

THE QUESTION OF CERTIFICATION AT GLASGOW.

A conference was held on April 24th at the City Chambers, Glasgow, between representatives of the medical profession and the managing bodies of the larger medical institutions in the city regarding the question of the certification for sickness benefit of insured persons while under treatment in institutions. The conference was called in consequence of a motion in the following terms adopted by the Glasgow Insurance Committee:—

> That a conference be arranged of representatives of the Insurance Committee, the Local Medical Committee, the Panel Committee, and institutions treating insured persons, with a view to securing coördination in the certification of insured persons for sickness benefit while under treatment in institutions.

There were present: Dr. A. Johnston and Dr. J. McKie, representing the Local Medical Committee; Dr. A. T. Campbell, Dr. Miller Semple, and Dr. James R. Drever, representing the Panel Committee; Dr. D. J. Mackintosh (Western Infirmary), Dr. D. O. Macgregor (Victoria Infirmary), Dr. J. Maxtone Thom (Royal Infirmary), Dr. W. J. Richard (Merryflatts Hospital), Dr. John Brownlie (Ruchill Hospital), representing their respective medical institutions; Dr. A. K. Chalmers (medical officer of health of the city); Dr. A. Macgregor, tuberculosis officer; Mr. R. D. McEwan, Mr. John Grieve, Mr. John Maillie, and Dr. J. Grant Andrew, representing the Insurance Committee; and Mr. William Jones, clerk to the committee.

The Chairman having referred briefly to the position of insured persons under treatment in institutions, to the inability of panel practitioners to grant the usual certificates of incapacity during such period, and to the delays which had occurred, particularly in cases where there were dependents, in making payment of sickness benefit through lack of the necessary certificates, a discussion ensued, which was taken part in by, among others, Dr. Mackintosh, Dr. Chalmers, Dr. Brownlie, Dr. McKie, Dr. Richard, Mr. Maillie, and Mr. Grieve. The following forms of certificates were submitted:—

GLASGOW ROYAL INFIRMARY.

This is to certify that ....
is at present under treatment in the Infirmary, and is unable for work.

_______________________, House Surgeon.

WESTERN INFIRMARY, GLASGOW.

This is to certify that ....
is at present an .... Patient of this Infirmary.

As the result of the views expressed by the several speakers, it was agreed that such institutions as may not be already doing so be recommended to adopt a form of certificate, certifying that the insured person is an inmate of the institution, similar to the forms in use at the Royal and Western Infirmaries, which forms, it was understood, were freely accepted by Approved Societies.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND TREATMENT BY UNQUALIFIED PERSONS.

The following resolution was passed by the Royal College of Surgeons in Ireland on April 19th in relation to the employment of non-qualified persons for the purpose of medical treatment under the National Insurance Act:—

> The College observes with regret that in Section 44 (2) of the National Health Insurance (Medical Benefit) Regulations, 1913, and the Memorandum issued in connexion therewith, provision is made whereby insured persons who make their own arrangements for medical benefit under Section 15 (3) of the National Insurance Act may obtain treatment from non-qualified persons.
>
> Hitherto none but duly qualified medical practitioners have been employed, as such, in any public capacity; and the College deplores that, under an Act professing to promote the health of the nation, recognition should be given and provision made for the payment of public money to a class of persons who have not obtained a legal qualification to practise medicine, and concerning whose medical knowledge there exists no sort of guarantee.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—C. Bluett (Sections I and II.), London Hospital; E. S. Dufty (Sections I. and II.), Sheffield; and B. C. Piercy (Sections I. and II.), Leeds.

Medicine.—C. Bluett (Section II.), London Hospital; W. Brown (Section I.), Oxford and King's College Hospital; M. Dos Santos (Section I.), Louvain and London Hospital; H. Dudley (Section I.), University College Hospital; D. M. Hunt (Section I.), London Hospital; W. Smith (Section II.), Durham; and A. K. S. Wyborn (Section I.), Middlesex Hospital.

Forensic Medicine.—W. Brown, Oxford and King's College Hospital; and N. W. Rawlings, Manchester.

Midwifery.—J. C. Gillies, Leeds; and G. Robinson, Manchester.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: C. Bluett, E. S. Dufty, and J. C. Gillies.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL: UNIVERSITY OF LONDON.—A course of lectures on the Pathology of the Heart will be begun by Dr. Thomas Lewis on Wednesday, May 6th, at 11 A.M. The lectures, which are free to all medical men, will include discussion on the following subjects: recent anatomical discoveries; principles of electrocardiography; causes of cardiac syncope and unexpected death; rapid action of the heart; auricular fibrillation and its relation to mitral stenosis; the diagnosis of fibrosis of the heart; alternation of the ventricles; heart sounds and murmurs; dyspnœa in cardiac patients; and hypertrophy with special reference to physical signs. One lecture will be delivered each week.

MARGATE CHAMBER OF COMMERCE. — The seventh annual banquet of the Margate Chamber of Commerce was held in the Queen's Hall, Queen's Highcliffe Hotel, Margate, on April 24th. The occasion possessed particular interest in view of the organised effort now taking place to establish an extension of the holiday season and also of the memorial signed by 250 members of the House of Commons urging the Government to grant facilities for the passage of the Health Resorts and Watering Places Bill. Amongst other things, this Bill seeks to give powers to seaside and health resort municipalities to invest money out of the rates for the purpose of increasing and making known the attractions of the place. As was pointed out by Mr. Norman Craig, K.C., M.P., in his speech at the banquet, the Chamber of Commerce at Margate has worked very hard to make known to the world the advantages of Margate. This, however, has been a purely voluntary movement, but it is an illogical thing that while Margate is able to speculate £30,000 in a pavilion, it cannot spend a penny of the ratepayers' money in advertising. The corporation may, in fact, speculate, but they must not invest. Mr. Craig said that it was hoped that a reform in this direction would be gained by the passing of the Health Resorts and Watering Places Bill. The Hon. Harry Lawson, M.P., who was the principal guest of the evening, has taken a considerable practical interest in the suggestions in regard to extending the holiday season, and there is every prospect of the matter receiving careful consideration not only by the governing authorities of our seaside and health resorts, but by the great railway companies also. The Margate Chamber of Commerce is continuing its good work, and the excellent propaganda which its members have actively put forward during its existence since 1899 in the interests of the health-seeking public and of the town has developed very encouraging results which should induce other watering places to found a similar organisation. Margate possesses a splendid asset in its wonderfully recuperative air.

Edinburgh University Club of London.—The jubilee dinner of this club will be held on Wednesday, May 13th, in the Grand Hall of the Hotel Cecil, at 7.30 P.M. Lord Balfour of Burleigh will preside.

South London Hospital for Women.—The annual general meeting of supporters of this hospital will be held at 35, Wimpole-street, W., on Wednesday, May 6th, at 3.30 P.M., when the chair will be taken by the Viscountess Castlereagh.

Tuberculin Dispensary League.—On Saturday, May 9th, at 12 o'clock noon, H.R.H. Princess Christian of Schleswig-Holstein will declare open the new dispensary at 1, Manor-street, Chelsea, S.W. The dispensary will be open for inspection from 2 till 6 o'clock.

The Port of Exeter and Small-pox.—At the last meeting of the Exeter port sanitary authority it was decided to support the Association of the Port Sanitary Authorities in their action of urging the Local Government Board to grant powers to port authorities to detain all vessels which have cases of small-pox on board. Such power is already granted for cases of cholera, yellow fever, or plague.

The Medical Difficulty at Droitwich.—The Droitwich board of guardians at their last meeting decided, after considerable discussion, to submit their difficulty in obtaining a medical officer to the Local Government Board. The guardians originally offered the post at £90 per annum. As there were no applications they increased the offer to £100, but this also proved unacceptable to the medical men of Droitwich. Meanwhile the acting medical officer has been asked to continue his duties until June 21st.

Conference on Morals.—The International Federation for the Abolition of the State Regulation of Vice, which met last year in Paris, will hold its annual conference for 1914 in Portsmouth from June 15th to 18th, when representatives are expected to attend from France, Denmark, Italy, and other foreign countries, in addition to members of the British branch. The problem to be considered will be "A Constructive Policy" in relation to the reduction of venereal disease and of public immorality. At a meeting of representatives of public bodies interested in social questions held at the town-hall, Portsmouth, on April 24th, an executive committee to make arrangements for the conference was appointed. It was resolved to ask permission of the international committee to give an opportunity to discuss the subject from its economic and educational aspects, which were not included in the agenda of the conference.

Metropolitan Public Gardens Association.—London owes a debt of gratitude to this association for the preservation of many acres of open land which otherwise would have been occupied by buildings. During the past year the association has been responsible for much good work, among which may be mentioned its coöperation in securing for public use the central enclosure of St. Peter's-square, Hammersmith, in the projects for the purchase of farm land adjoining Wandsworth Common, in the extension of Valentine's Park, Ilford, and in the acquisition of Colley Hill, Reigate. The laying out of gardens in the large churchyard of St. Paul, Deptford, was also undertaken by the association; and its activities on behalf of the Wimbledon Common and Putney Heath Extension Scheme and the Wandle River open spaces have been attended with good results. These and other works have, however, entailed an expenditure greater than the actual income, which amounted to £2058, a deficit remaining on the year's working of £518. The association was formed in 1882 to supply one of the most pressing needs of the poorer districts of London by providing resting-places for the old and playgrounds for the young in the midst of densely populated districts, and no one can read the detailed work of the association in the annual report for 1913, which is published at 83, Lancaster Gate, price 6*d*., without realising the importance of the work and the need for its extension. A map of London on the scale of 1½ inches to the mile contained in the report is especially worthy of study.

Royal Society of Arts.—At the ordinary meeting at John-street, Adelphi, London, W.C., on Wednesday, May 6th, at 8 P.M., the paper on Inexpensive Motoring, by Mr. A. Ludlow Clayden, should prove of interest to many medical practitioners.

Post-Graduate College, West London Hospital.—A conversazione will be held at the West London Hospital, Hammersmith, by the staff of the college on Wednesday, May 20th, at 8.30 P.M. Exhibitions and music will form part of the entertainment, and refreshments and smoking will be provided.—The summer session of the college will commence on Monday, May 11th.

The Lord Mayor Treloar's Cripples' Hospital and College.—The first festival dinner of this useful institution, which is situated at Alton, Hants, will be held on Wednesday, May 13th, in the Merchant Taylors' Hall, Threadneedle-street, City. The chair will be taken by the Right Hon. Arthur J. Balfour, M.P., at 7.30 P.M.

Exhibition of the Arts and Industries of the Blind.—This exhibition will be held in connexion with the International Conference on the Blind at the Church House, Great Smith-street, Westminster, London, from June 18th to 24th, both dates inclusive. It will be open from 10 to 1, 2.30 to 7, and from 8 to 10 each day, Sunday excepted. There will be a charge for admission, but entrance will be free to members of the Conference on showing their cards of invitation. The exhibits will include (*a*) goods made by the blind; (*b*) machines, apparatus, books, &c., which may be used by the blind; and (*c*) objects, books, pictures, &c., illustrating the history, education, and training of the blind or connected with blindness or with notable blind men and women. A catalogue will be printed, and the forms of particulars of exhibits must be returned to Mr. Stuart Johnson, care of Miss J. B. Weippert, 110, Loughborough-park, S.W., by May 18th, but blind persons should send their exhibits to the societies for the blind with which they may be connected or else to the local secretaries not later than May 8th, who in their turn will send all exhibits to the Church House not later than June 8th. No charge will be made for space except to firms exhibiting goods under Class B. All correspondence connected with the exhibition should be addressed to Mr. Stuart Johnson, 64, Denison House, 296, Vauxhall Bridge-road, London, S.W., and marked outside "Exhibition." Persons possessing or knowing of objects likely to form interesting exhibits or desiring to assist in the work of the exhibition are requested to write at once.

International Society for Sexual Research.—This society is organising its first congress, to be held in Berlin this year from Oct. 31st to Nov. 2nd. The congress will cover the entire field of scientific sexual research, and will probably be divided into a biological-medical, a sociological, a legal (including criminal anthropology and psychology), and a philosophic-psychological-pedagogical section. The proceedings will be conducted in German, English, and French, the president being further empowered in special cases to permit the use of other languages. The following addresses are announced:—Professor Dr. Broman, Lund, "Causes and Spread of Natural Sterility and its Share in the Decreasing Birth-rate"; Professor Dr. Hans Gross, Graz, "Comparative Criminal Psychology of the Sexes"; Professor Dr. Ch. Klumker, Frankfurt a.M., and Pastor Wilhelm Pfeiffer, "What is to Become of the World's Illegitimate Children?"; Professor Dr. Mingazzini, Rome, "Female Criminality and Menses"; Professor Dr. W. Mittermaier, Giessen, "The Attitude of Criminal Law to Sexual Crimes in the Course of History"; Dr. Albert Moll, "On the Psychology, Biology, and Sociological Place of the Old Maid"; Professor Dr. Sellheim, "Propagation and Readiness to Propagate as the Task of Woman"; Professor Dr. E. Steinach, Wien, "Receptivity to Influence of the Sexual Characteristics"; Professor Dr. S. Steinmetz, Amsterdam, "The Individual Factor in Race-Blending"; Geh. Reg. Rat Professor Dr. Julius Wolf, Berlin, "Sexual Science as a Science of Education and Civilisation." Participation in the congress is free to members of the society. Non-members are expected to pay a registration fee of 10 marks. All inquiries respecting the congress and the society should be directed to Dr. Max Marcuse, Berlin W.35, Lützowstr. 85.

RURAL MIDWIVES ASSOCIATION.—The eleventh annual meeting of this association will be held at 3, Grosvenor-place, London, S.W., on Tuesday, May 5th, at 3.15 P.M., under the presidency of the Marchioness of Tullibardine. Miss Margaret Awdry will speak on Infant Mortality, and Mr. Francis E. Fremantle on Coöperation of Voluntary Associations with Public Bodies in Rural Areas.

MEDICAL RESEARCH IN CHINA.—With the object of ascertaining the mode of spread of trematode diseases of man and the relations of such human diseases to those in domestic animals, a party consisting of Dr. R. T. Leiper, of the London School of Medicine, Surgeon E. L. Atkinson, R.N., and Mr. Cherry-Gerrard has recently arrived in Shanghai. They will first ascend the Yangtze river and spend several months in the interior of China. The London School of Tropical Medicine is responsible for the despatch of the party.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Milk Legislation.

MR. HERBERT SAMUEL'S promise to expedite the introduction of a Milk Bill has been well received by those Members who have been pressing for legislation on this matter for years. Indeed, the object of Mr. ASTOR'S motion on Wednesday, April 22nd, was primarily directed to impress on the Government the necessity for a Bill on the subject. Mr. BURNS when he was at the Local Government Board desired to deal with the milk problem, and although he introduced a measure it was not found possible to press it in the face of the opposition of the dairy interest to some of its provisions. Mr. SAMUEL'S Bill will be more restricted than the one produced by Mr. BURNS.

HOUSE OF LORDS.

THURSDAY, APRIL 23RD.

Midwives (Scotland) Bill.

Lord BALFOUR of BURLEIGH, in moving the second reading of the Midwives (Scotland) Bill, said that the communications which had been received with reference to the Bill since it was introduced were entirely favourable, but a number of drafting amendments had been suggested.

The second reading was agreed to without debate.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 22ND.

Mortality Amongst Seamen.

Mr. MCGHEE asked the President of the Board of Trade whether his attention had been called to the statistics relating to mortality amongst seamen on British ships; and whether he proposed to take any steps in the matter.—Mr. BURNS answered: I am aware of the statistics to which my honourable friend refers, and by my direction the whole question of seamen's mortality is now being investigated by officers of my department in consultation with representatives of the Local Government Board and the General Register Office.

THURSDAY, APRIL 23RD.

Form of Declaring-on Certificate.

Mr. CHARLES BATHURST asked the honourable Member for St. George's-in-the-East, as representing the Insurance Commissioners, whether he was aware of the feeling among Approved Societies and their various organisations that the form of declaring-on certificate, Medical 34, issued by the Insurance Commissioners to panel doctors, should bear upon it words to the effect that the certificate should be sent in to the society immediately it was signed; and whether he would take steps to have the desired alteration carried into effect.—Mr. WEDGWOOD BENN replied: The question of the revision of the form in the manner referred to by the honourable Member is now under the consideration of the Insurance Commissioners.

Mr. BATHURST: How long will it be before this consideration leads to action?—Mr. WEDGWOOD BENN: The honourable gentleman has just made a suggestion which will be acted on if it is a good one.

Mr. BATHURST: Was it brought to the knowledge of the Commissioners many months ago?—Mr. WEDGWOOD BENN: Not to my knowledge.

Stoke-on-Trent Panel.

Sir HENRY CRAIK asked the honourable Member for St. George's-in-the-East whether his attention had been called to the delay which had occurred in paying the doctors on the Stoke-on-Trent panel, and whether the Insurance Commissioners could bring to an end a state of matters which inflicted heavy loss upon the doctors who had undertaken to serve under the Act.—Mr. WEDGWOOD BENN answered: My right-honourable friend is not aware that any avoidable delay has arisen in the case referred to. He is informed that the doctors in question have already been paid 94 per cent. of the amount estimated to be available for their remuneration, and as a matter of fact the accounts, with a view to a settlement, are in the hands of the doctors themselves for agreement by them.

MONDAY, APRIL 27TH.

Hop Substitutes in Brewing.

Mr. DUNDAS WHITE asked the President of the Board of Agriculture whether he would state what hop substitutes were used in the brewing or preparation of beer which were deleterious to health and were not already prohibited by the Sale of Food and Drugs Acts or other statutes.—Mr. HERBERT LEWIS (on behalf of Mr. RUNCIMAN) replied: The proposed legislation is not based on the assumption that hop substitutes are deleterious to health, and I am not prepared to say whether or not any hop substitutes can be so described.

Medical Cards.

Mr. DENNISS asked the honourable Member for St. George's-in-the-East what was the number for England, Wales, and Scotland respectively of insured persons' medical cards which had not been delivered by the Post Office to the addressee; where those cards were at present; what steps were being taken, or were proposed to be taken, to find the addressees and deliver the cards; and whether the Approved Societies had been invited to furnish the addresses of those of their members whose medical cards had been returned through the post; and, if so, with what result.—Mr. WEDGWOOD BENN answered: The numbers of medical cards returned through the Post Office are approximately 800,000, 125,000, and 20,000. These cards are with the Insurance Committees by whom they were issued; and steps are being taken in many cases to trace addressees by means of the sources of information accessible, including Approved Societies. Apart from any such steps cards had been issued upon application to a very large number of insured persons who did not receive a card upon the initial distribution.

TUESDAY, APRIL 28TH.

Notification of Infectious Diseases.

Mr. WING asked the President of the Local Government Board whether he would amend the Notification of Infectious Diseases Act, by order or otherwise, in such a manner as to make it compulsory on the part of private medical attendants to inform parents as to the nature of the illness of their children and its infectious character, and advise as to the exclusion of children from school pending the arrival of the medical officer of health; and whether he was aware that this proposal was recommended by several public officers of health.—Mr. HERBERT SAMUEL replied: I am aware that a suggestion of this kind has been made in the report of a medical officer of health, but I have received no representations on the subject. Legislation would be required to give effect to the suggestion, and I am not at present convinced of the necessity for adopting compulsion in this matter.

WEDNESDAY, APRIL 29TH.

Unallocated Panel Surplus in London.

Sir J. D. REES asked the honourable Member for St. George's-in-the-East whether the Government had sanctioned the distribution proposed by the London Insurance Committee of the unallocated surplus of about £200,000 in the panel fund to the doctors on the panel; and whether legal advice had been taken by the Insurance Commissioners as to the legality of such distribution.—Mr. WEDGWOOD BENN replied: The proposals of the London Insurance Committee as to the manner in which the sum at issue (the amount of which is overstated in the question) is to be distributed among the doctors have not as yet been submitted to the Insurance Commissioners.
